Abstract

Assuming CP violation arises solely through the Higgs potential, we develop the most general two-Higgs doublet model. There is no discrete symmetry that distinguishes the two Higgs bosons. It is assumed that an approximate global family symmetry sufficiently suppresses flavor-changing neutral scalar interactions. In addition to a CKM phase, neutral boson mixing, and superweak effects, there can be significant CP violation due to charged Higgs boson exchange. The value of $\epsilon'/\epsilon$ due to this last effect could be as large as in the standard model.

PACS numbers: 11.30.Er, 12.15.Cc
In gauge theories the standard gauge interaction is CP invariant so that the origin of CP violation always lies in the Higgs potential or the Yukawa interaction of the Higgs bosons with fermions. In the standard model with only a single Higgs doublet the only way to introduce CP violation is via complex Yukawa couplings. The simplest extension of the standard electroweak theory is to include two Higgs doublets instead of one. As a consequence there exist a variety of new sources of CP violation.

The most general Higgs potential for this case can be written

\[ V(\phi_1, \phi_2) = -\mu_1^2 \phi_1^\dagger \phi_1 - \mu_2^2 \phi_2^\dagger \phi_2 - (\mu_{12}^2 \phi_1^\dagger \phi_2 + h.c.) \]

\[ + \lambda_1 (\phi_1^\dagger \phi_1)^2 + \lambda_2 (\phi_2^\dagger \phi_2)^2 + \lambda_3 (\phi_1^\dagger \phi_1 \phi_2^\dagger \phi_2) + \lambda_4 (\phi_1^\dagger \phi_2)(\phi_2^\dagger \phi_1) \]

\[ + \frac{1}{2} [\lambda_5 (\phi_1^\dagger \phi_2)^2 + h.c.] + [\lambda_6 \phi_1^\dagger \phi_1 + \lambda_7 \phi_2^\dagger \phi_2] (\phi_1^\dagger \phi_2) + h.c. \] (1)

With \( \lambda_5 \) non-zero and real, CP violation can arise from non-zero values of one or more of \( \mu_{12}^2, \lambda_6 \) or \( \lambda_7 \). If these three (and \( \lambda_5 \)) are all real, CP violation can occur spontaneously when \( \lambda_5 > 0 \), because of the relative phase \( \delta \) between the vacuum expectation values (vevs)

\[ \langle \phi_1^0 \rangle = \frac{v}{\sqrt{2}} \cos \beta e^{i\delta}, \quad \langle \phi_2^0 \rangle = \frac{v}{\sqrt{2}} \sin \beta \] (2)

If one of \( \mu_{12}^2, \lambda_6 \) or \( \lambda_7 \) is complex there is explicit CP violation in the Lagrangian. In the models we discuss in this paper we assume that the Yukawa couplings are real so that the only source of CP violation comes from \( V(\phi_1, \phi_2) \). Whether the CP violation is spontaneous or explicit the consequences of interest all depend on the phase \( \delta \) in eq.(2).

A major issue with respect to multi-Higgs models is the possibility of flavor-changing processes mediated by the exchange of neutral scalar bosons (FCNE). There exist strong limits on FCNE from \( K^0 - \bar{K}^0 \) and \( B^0 - \bar{B}^0 \) mixing and from semi-leptonic processes like \( K_L \to \mu^+ \mu^- \) and \( B \to X \mu^+ \mu^- \). Following a theorem of Glashow and Weinberg it is often proposed to impose a discrete symmetry on the two-Higgs model under which

\[ \phi_1 \to -\phi_1, \quad \phi_2 \to \phi_2; \] (3)

\[ D_{R_i} \to D_{R_i} \quad \text{or} \quad D_{R_i} \to -D_{R_i}, \quad U_{R_i} \to U_{R_i} \] (4)
where $D_{R_i}$ and $U_{R_i}$ are the usual right-handed quarks with $i = 1 - 3$. As a result, only $\phi_2$ gives mass to up quarks and only $\phi_1$ or only $\phi_2$ gives mass to down quarks. Thus as in the standard model the final scalar boson couplings are proportional to the mass matrix and do not change flavor. It also follows from eq. (3) that the coefficients $\mu_{12}^2$, $\lambda_6$, and $\lambda_7$ in eq. (1) vanish so that no CP violation results from $V(\phi)$. Thus as in the standard model with one doublet the only source of CP violation is the complex Yukawa couplings, which lead to a phase in the CKM quark mixing matrix.

Various ways of modifying the restrictions of eqs. (2) and (3) have been proposed:

(1) The discrete symmetry of eq. (3) is violated only softly by the term proportional to $\mu_{12}^2$ and this is the only source of CP violation. In order to obtain the needed CP violation in the quark sector it is necessary to modify eq. (4) so that $d_{R_i} \rightarrow \eta_i d_{R_i}$ where $\eta_i$ is $(+1)$ for some generations and $(-1)$ for others [3]. The consequences of such a model have been worked out in detail by Lavoura [4], he finds this is a truly superweak [5] model with no CKM phase.

(2) The discrete symmetry defined by eqs. (3-4) is violated both in $V(\phi)$ and the Yukawa sector but the violation everywhere is small. This model discussed in detail by Liu and Wolfenstein [6] also leads to superweak CP violation but there exists in addition a non-zero CKM phase. Furthermore, the value of $\epsilon'/\epsilon$ is greater than in generic superweak models and is expected to lie between $10^{-4}$ and $10^{-6}$.

(3) One can abandon the discrete symmetry altogether and assume that an approximate family symmetry suppresses FCNE. The point here is that the smallness of the off-diagonal terms in the CKM matrix suggests that violation of flavor symmetry (described by a set of global U(1) transformations) are specified by small parameters. It then turns out that reasonable choices for these small parameters combined with the natural smallness of Higgs couplings allows one to meet the constraints on FCNE. This point made by Cheng and Sher has recently been reemphasized by Hall and Weinberg [7]. The consequences of this general assumption have been worked out in detail [8] by considering Approximate Global U(1) Family Symmetries (AGUFS) (i.e., one for each family) and is the major subject to be
emphasized in this note. Unlike Hall and Weinberg, we do not impose a particular formula for the small parameters. Of particular importance is a new source of CP violation for charged Higgs boson interactions that can lead to a value of $\epsilon'/\epsilon$ as large as $10^{-3}$ independent of the CKM phase.

After spontaneous symmetry breaking it is natural to use as a basis for the neutral Higgs fields

$$(v + H^0 + iG^0)/\sqrt{2} = \cos \beta \phi_1^0 e^{-i\delta} + \sin \beta \phi_2^0$$

$$(R + iI)/\sqrt{2} = \sin \beta \phi_1^0 e^{-i\delta} - \cos \beta \phi_2^0$$

Here $H^0$ is the "real" Higgs boson and $G^0$ is the Goldstone boson eaten up by $Z^0$. The orthogonal state $(R + iI)$ forms a doublet with the charged Higgs $H^\pm$. The neutral mass eigenstates $H^0_1, H^0_2, H^0_3$ are related to $(R, H^0, I)$ by an orthogonal matrix $O^H$.

The original Yukawa interaction has the general form

$$L_Y = \bar{\psi}_L (\Gamma_1 \phi_1 + \Gamma_2 \phi_2) D_R$$

plus a similar term in $U_R$. Here $\Gamma_1, \Gamma_2$ are matrices in flavor space and $\psi_L$ is the quark doublet $(U_L, D_L)$. The assumption of Approximate Global U(1) Family Symmetries (AGUFS) says that $\Gamma_1, \Gamma_2$ have small off-diagonal elements, typically between 0.2 and 0.01 of the related diagonal element in order to fit the known CKM matrix as well as the constraints on FCNE, i.e., AGUFS are sufficient for a natural suppression of family-changing currents (for both charged and neutral currents). From $L_Y$ one derives the mass matrices which are diagonalized in the usual way introducing the mass basis $u_L, u_R, d_L, d_R$ and the CKM matrix $V$.

We now rewrite $L_Y$ in terms of the Higgs basis of eq. (5) and the quark mass basis. We divide the result into a term $L_1$, which has no flavor-changing effects other than that expected for $H^\pm$ from the CKM matrix $V$, and $L_2$, which contains the flavor-changing effects for neutral bosons as well as small additional flavor-changing terms for $H^\pm$.

$$L_Y = (L_1 + L_2) \cdot (\sqrt{2}G_F)^{1/2}$$

(7)
with

\[ L_1 = \sqrt{2}(H^+ \sum_{i,j}^3 \xi_{d_j} m_{d_j} V_{ij} \bar{u}_L^i d_R^j \bar{d}_j u_R^j - H^- \sum_{i,j}^3 \xi_{u_j} m_{u_j} V_{ij}^\dagger \bar{u}_L^i u_R^j) \]

\[ + H^0 \sum_i^3 (m_{u_i} \bar{u}_L^i u_R^i + m_{d_i} \bar{d}_i u_R^i) \]

\[ +(R + iI) \sum_i^3 \xi_{d_i} m_{d_i} \bar{d}_i u_R^i + (R - iI) \sum_i^3 \xi_{u_i} m_{u_i} \bar{u}_L^i u_R^i + H.C. \] (8)

\[ L_2 = \sqrt{2}(H^+ \sum_{i,j}^3 V_{ij} \mu_{d_j}^{d_j} \bar{u}_L^i d_R^j - H^- \sum_{i,j}^3 V_{ij}^\dagger \mu_{u_j}^{u_j} \bar{d}_j u_R^i) \]

\[ +(R + iI) \sum_{i \neq j}^3 \mu_{d_j}^{d_j} \bar{d}_i d_R^i + (R - iI) \sum_{i \neq j}^3 \mu_{u_j}^{u_j} \bar{u}_L^i u_R^j + H.C. \] (9)

Where the factors \( \xi_{d_j} m_{d_j} \) arise primarily from diagonal elements of \( \Gamma_1 \) and \( \Gamma_2 \) whereas the factors \( \mu_{d_j}^{d_j} \) arise from the small off-diagonal elements.

There are four major sources of CP violation:

1. The CKM matrix. In addition to the usual CP violation in \( W^\pm \) exchanges there is also in all two-Higgs models a similar CP violation in the charged-Higgs sector.

2. The phases in the factors \( \xi_{f_i} \) provide CP violation in the charged-Higgs exchange processes that is independent of the CKM phases. These phases also yield CP violation in flavor-conserving \( R \) and \( I \) interactions.

3. The phases in the factors \( \mu_{ij}^f \). These yield CP violation in FCNE.

4. From the Higgs potential one derives the matrix \( O^H \) that diagonalizes the Higgs mass matrix. Even in the absence of fermions this \( O^H \) may violate CP invariance. This violation may also be described by an invariant analogous to the Jarlskog invariant for the CKM matrix. In models in which the CP violation in \( L_Y \) is negligible this is the major source of CP violation in effective quark interactions due to Higgs exchange.

A unique feature of the present analysis is the importance of the factors \( \xi_{f_i} \). To illustrate the origin of these factors one can simply neglect the off-diagonal elements in \( \Gamma_1 \) and \( \Gamma_2 \) of eq. (6). (This should be a reasonable approximation for the second and third generations although possibly not for the first.) For example, for the third down generation one finds
\[ m_3 e^{i\delta_3} = (g_1 \cos \beta e^{i\delta} + g_2 \sin \beta) v \]

where \( m_3 \) is the mass, \( \delta_3 \) is a phase associated with the mass, and \( g_1(g_2) \) is the 33 element of \( \Gamma_1(\Gamma_2) \). One gets rid of \( \delta_3 \) by redefining \( d_{R3} \). The corresponding coupling of \((R+iI)\) then is derived from eqs. (5) and (6) as

\[ (g_1 \sin \beta e^{i\delta} - g_2 \cos \beta) v e^{-i\delta_3} \equiv \xi_{d3} m_3 \]

If \( g_1 \) and \( g_2 \) are comparable in magnitude \( \xi_{d3} \) is of order unity and has a phase like \( \delta \). For example, if \( \delta = \pi/2 \) and \( g_1 = g_2 \) then the phase of \( \xi_{d3} \) is \( \pi/2 \) independent of \( \beta \). For large values of \( \tan \beta \) and \( \delta = \pi/2 \) one can show \( \xi_{d3} \approx i \tan \beta \sin \delta_3 e^{-i\delta_3} \) so that for a range of \( \delta_3 \) (corresponding to a range of \( g_2/g_1 \)) one can obtain an enhanced value of \( \xi_{d3} \) with a sizable phase. This same factor \( \xi_{d3} \) enters in the \( H^\pm \) couplings multiplied by the CKM matrix.

Some of the most distinctive features of these new sources of CP violation are

1. The factor \( \xi_{fj} \) provide phases in charged Higgs exchange that can provide CP violation in tree level flavor changing amplitudes. The important point is that these phases are in addition to and essentially independent of the CKM phase for each particular transition. For \( \Delta S = 1 \) transitions the charged Higgs boson exchange makes a contribution to \( \epsilon'/\epsilon \) which has the order of magnitude between \( 10^{-4} \) and \( 10^{-5} \) for \( \tan \beta \sim 1 \) but which could be as large as \( 10^{-3} \) for large values of \( \tan \beta \) (numerically, as long as \( \tan \beta \sim 10(m_{H^\pm}/200\text{GeV}) \) without conflicting with other constraints. Thus a measurement of \( \epsilon'/\epsilon \) at this level would not necessarily be due to CP violation of the CKM type.

2. There may be significant contributions to \( \epsilon \) from superweak FCNE and also from box diagrams containing \( H^\pm \).

3. The expectations for CP violation in the \( B^0 \) system can be seriously changed. Even if the Higgs bosons make little contributions to \( B^0 - \bar{B}^0 \) mixing their contribution to \( \epsilon \) change the constraints on the parameter \( \eta \) of the CKM matrix, allowing, for example, the opposite sign for the \( \psi K_s \) asymmetry. It is also possible that there may be large superweak or charged-Higgs-box-diagram contributions to \( B^0 - \bar{B}^0 \) mixing greatly changing the range of the asymmetries.
(4) As is well-known there are many contributions to electric dipole moments in the Higgs models of CP violation. Of particular interest are the two-loop graphs discussed by Barr-Zee [13]. These contribute to the electric dipole moment $D_n$ of the neutron via the chromo-electric dipole moment [14] and directly to the electron dipole moment $D_e$ of the electron through the neutral Higgs boson exchanges. In the present model because of the presence of the complex factor $\xi_t$ (and other $\xi_f$ factors), $D_n$ can receive a large contribution from the Weinberg gluonic operator through the charged Higgs boson exchange and $D_e$ can also receive a contribution by the same two-loop Barr-Zee mechanism but with virtual photon replaced by the W-boson and the neutral Higgs boson replaced by the charged Higgs boson. The contribution to $D_e$ from this two-loop diagram with charged Higgs boson exchange is comparable to that with neutral Higgs boson exchange. From both charged and neutral Higgs boson contributions to $D_n$ and $D_e$, values of $D_n$ of the order $10^{-25}$ to $10^{-26}$ e-cm and of $D_e$ of the order $10^{-26}$ to $10^{-27}$ e-cm close to the present limits are allowed without conflicting with other constraints.

In conclusion, the simplest extension of the standard model, the two-Higgs doublet model, provides rich possibilities for sources of CP violation in addition to that from the standard CKM model. All these can arise from a single phase between the vacuum expectation values of the two bosons. In particular, we have emphasized the significant CP-violating effects involving exchange of charged-Higgs bosons in a class of models in which the usual discrete symmetry is abandoned.
