Abstract
Background: In various researches it was reported that perforations of gastrointestinal tract had been surgical emergencies. Some studies also reported that the proof of gastrointestinal tract perforations in ancient mummies. Gastrointestinal tract perforation occurs when a pathology of any specific disease involves the entire depth of the gastrointestinal tract
Material & Methods: Patients who were diagnosed as perforation and peritonitis on the basis of laboratory diagnosis and clinical examination were enrolled by simple random sampling. Clearance from Institutional Ethics Committee was taken before start of study. Written informed consent was taken from each study participant.
Results: In the present study, out of total study participants abdominal pain was the most common presenting symptom present in patients which was followed by fever, abdominal distension and vomiting. On the basis of time of perforation, 4% cases presented within 12 hour, between 12 and 24 hour was reported among in 50% cases, in the rage of 24 and 48 hour seen in 24% patients, in the range of 48 and 72 hour reported in 12% cases, in range of 72 and 96 hour reported in 8% cases, and in range of 96 and 120 hour reported in 2% case. Near about all patients were operated in the range of 12 hours of hospitalization.
Conclusion: The most common presenting symptoms present among patients were abdominal pain, abdominal distension, vomiting, fever and obstruction. We found that majority of cases had circular perforation of typhoid at antimesenteric border which was followed by tubercular elliptical perforation on the antimesenteric border and traumatic type perforation.
Key words: Ileal perforation, primary closure, loop ileostomy

INTRODUCTION
In various researches it was reported that perforations of gastrointestinal tract had been surgical emergencies (1). Some studies also reported that the proof of gastrointestinal tract perforations in ancient mummies. Gastrointestinal tract perforation occurs when a pathology of any specific disease involves the entire depth of the gastrointestinal tract (2). Gastrointestinal tract perforation leads to the contamination of peritoneal cavity with intestinal contents. In various researches it was reported that perforations can be occurred anywhere in full length of gastrointestinal tract. In various researches it was reported that ileal perforation are common surgical emergencies especially in the tropical area of world and particularly in India (3). Some studies also reported that ileal perforations are accounts for near about 20% of total abdominal surgical emergencies. The most prevalent causes reported are tuberculosis and enteric fever (4).

In various researches it was reported that ileal perforation had an high incidence of mortality, longer hospital stays and economic burden on patients. previous studies were reported various causes of ileal perforation which includes tuberculosis, salmonella infection, Yersinia infection, cytomegalovirus, human immunodeficiency virus, histoplasma, A. lumbricoides, E. histolytica and Nonsteroidal anti-inflammatory drugs (5). There were various operative procedures were reported in various researches which are simple primary repair, management by repair with ileo-transverse colostomy, management by single layer repair with an omental patch and management by resection and anastomosis and management by primary ileostomy (6). We conducted the present study to assess the surgical profile among patients of ileal perforation.

MATERIALS & METHODS
The present prospective study was conducted at department of general surgery of our tertiary care
hospital. The study duration was of two years from June 2016 to July 2018. A sample size of 50 was calculated at 95% confidence interval at 5% acceptable margin of error by epi info software version 7.2. Patients who were diagnosed as perforation and peritonitis on the basis of laboratory diagnosis and clinical examination were enrolled by simple random sampling. Clearance from Institutional Ethics Committee was taken before start of study. Written informed consent was taken from each study participant.

The data were collected by predesigned Performa after randomization of the patients among two groups according to surgical procedure group A (primary repair) and group B (loop ileostomy). Patients who had chronic debilating diseases, patients who were on steroid therapy or suffering from malignancy were excluded from the present study. The antibiotics (ceftriaxone, ceftazidine and metronidazole) were given in both groups before surgery. Data analysis was carried out using SPSS v22. All tests were done at alpha (level significance) of 5%; means a significant association present if p value was less than 0.05.

RESULTS

In the present study, out of total study participants abdominal pain was the most common presenting symptom present in patients which was followed by fever, abdominal distension and vomiting. On the basis of time of perforation, 4% cases presented within 12 hour, between 12 and 24 hour was reported among in 50% cases, in the rage of 24 and 48 hour seen in 24% patients, in the range of 48 and 72 hour reported in 12% cases, in range of 72 and 96 hour reported in 8% cases, and in range of 96 and 120 hour reported in 2% case. Near about all patients were operated in the range of 12 hours of hospitalization. We found that majority of cases had circular perforation of typhoid at antimesenteric border which was followed by tubercular elliptical perforation on the antimesenteric border and traumatic type perforation. (Table 2)

| Presenting symptom | Number of patients |
|--------------------|--------------------|
| Abdominal pain      | 61%                |
| Fever               | 52%                |
| Abdominal distension| 46%                |
| Vomiting            | 42%                |
| Obstruction         | 40%                |
| Trauma              | 4%                 |

DISCUSSION

In the present study, out of total study participants abdominal pain was the most common presenting symptom present in patients which was followed by fever, abdominal distension and vomiting. On the basis of time of perforation, 4% cases presented within 12 hour, between 12 and 24 hour was reported among in 50% cases, in the rage of 24 and 48 hour seen in 24% patients, in the range of 48 and 72 hour reported in 12% cases, in range of 72 and 96 hour reported in 8% cases, and in range of 96 and 120 hour reported in 2% case. Near about all patients were operated in the range of 12 hours of hospitalization. We found that majority of cases had circular perforation of typhoid at antimesenteric border which was followed by tubercular elliptical perforation on the antimesenteric border and traumatic type perforation. (Table 1)

| Parameters | primary repair | loop ileostomy | p value |
|------------|----------------|----------------|---------|
| Age (Years) | 21-40          | 16 (32%)       | 15 (30%) | >0.05 |
|            | 41-60          | 30 (60%)       | 32 (64%) |
|            | 61-80          | 4 (8%)         | 3 (6%)  |
| Gender     | Male           | 38 (76%)       | 36(72%) | >0.05 |
|            | Female         | 12 (24%)       | 14(28%) |

In the present study, out of total study participants abdominal pain was the most common presenting symptom present in patients which was followed by fever, abdominal distension and vomiting. On the basis of time of perforation, 4% cases presented within 12 hour, between 12 and 24 hour was reported among in 50% cases, in the rage of 24 and 48 hour seen in 24% patients, in the range of 48 and 72 hour reported in 12% cases, in range of 72 and 96 hour reported in 8% cases, and in range of 96 and 120 hour reported in 2% case. Near about all patients were operated in the range of 12 hours of hospitalization. We found that majority of cases had circular perforation of typhoid at antimesenteric border which was followed by tubercular elliptical perforation on the antimesenteric border and traumatic type perforation. (Table 1)
group of 41-60 years and 3 (6%) patients were in the age group of 61-80 years. However, this distribution was statistically non-significant (P value >0.05). Among the primary repair group, 38 (76%) patients were male and 12 (24%) patients were female. Among the ileostomy closure group, 36 (72%) patients were male and 14 (28%) patients were female. However, this distribution was statistically non-significant (P value >0.05). Similar results were obtained in a study conducted by Wani et al among patients with perforation of gastrointestinal tract they reported that higher prevalence of males were affected than females in the ratio of 3:1 (7). Similar results were obtained in a study conducted by Adesunkanmi et al among patients with perforation of gastrointestinal tract they reported that higher prevalence of males were affected than females in the ratio of 4:1 (8).

In the present study, out of total study participants abdominal pain was the most common presenting symptom present in patients which was followed by fever, abdominal distension and vomiting. Similar results were obtained in a study conducted by Talwar et al among patients with perforation of gastrointestinal tract they reported that abdominal pain was the most common presenting symptom present in patients which was followed by fever, abdominal distension, vomiting and obstipation (9). Similar results were obtained in a study conducted by Beniwal et al among patients with perforation of gastrointestinal tract they reported that the most common presenting symptoms present among patients were abdominal pain, abdominal distension, vomiting, fever and obstipation (10). Similar results were obtained in a study conducted by Prasad et al among patients with perforation of gastrointestinal tract they reported that the most common presenting symptoms present among patients were abdominal pain, abdominal distension, vomiting and obstipation (11).

In the present study, on the basis of time of perforation, 4% cases presented within 12 hour, between 12 and 24 hour was reported among in 50% cases, in the rage of 24 and 48 hour seen in 24% patients, in the range of 48 and 72 hour reported in 12% cases, in range of 72 and 96 hour reported in 8% cases, and in range of 96 and 120 hour reported in 2% case. Near about all patients were operated in the range of 12 hours of hospitalization. Similar results were obtained in a study conducted by Nadkarni et al among patients with perforation of gastrointestinal tract they reported that majority of patients were presented within 90 hours based on time of perforation (12).

In the present study, we found that majority of cases had circular perforation of typhoid at antimesenteric border which was followed by tubercular elliptical perforation on the antimesenteric border and traumatic type perforation. Similar results were obtained in a study conducted by Nadkarni et al among patients with perforation of gastrointestinal tract they reported that most common etiology was nonspecific cause of ileal intestinal tract which was followed by typhoid and tubercular perforation (12). Similar results were obtained in a study conducted by Visser A et al among patients with perforation of gastrointestinal tract they reported that most common etiology was typhoid and tubercular perforation (13).

CONCLUSION

We concluded from the present study that the most common presenting symptoms present among patients were abdominal pain, abdominal distension, vomiting, fever and obstipation. We found that majority of cases had circular perforation of typhoid at antimesenteric border which was followed by tubercular elliptical perforation on the antimesenteric border and traumatic type perforation.
