The dihedral Dunkl–Dirac symmetry algebra with negative Clifford signature

Alexis Langlois-Rémillard

Abstract The Dunkl–Dirac symmetry algebra is an associative subalgebra of the tensor product of a Clifford algebra and the faithful polynomial representation of a rational Cherednik algebra. In previous work, the finite-dimensional representations of the Dunkl–Dirac symmetry algebra in three dimensions linked with a dihedral group were given. We give here the necessary results to proceed to the same construction when the Clifford algebra in the tensor product has negative signature.

1 Introduction

Dunkl operators [3] generalise partial derivatives by introducing terms related to a reflection group \( W \subset O(N) \), its associated root system \( R \), and a function \( \kappa : R \to \mathbb{C} \) invariant on the \(^W\)-orbits. Together with the multiplication operators and the group algebra \( \mathbb{C}[W] \), they generate an associative algebra \( \mathcal{A}_\kappa \) that is the faithful polynomial representation of a rational Cherednik algebra [4]. Given a Clifford algebra \( Cl(N) \), there is an \( osp(1|2) \)-realisation inside the tensor product \( \mathcal{A}_\kappa \otimes Cl(N) \) generated by the Dunkl–Dirac operator obtained by changing the partial derivatives by Dunkl operators and its dual symbol. The symmetry algebra \( \mathcal{SA}_m \) linked to a family of \( osp(1|2) \)-realisations containing the Dunkl realisation mentioned was characterised abstractly in [1], and it was shown in [6] that it is the full \( osp(1|2) \)-supercentraliser. The representation theory of these algebras is only known for a few specific cases. In a recent article [2], we constructed the finite-dimensional representations of the dihedral Dunkl–Dirac symmetry algebra \( \mathcal{A}_m \subset \mathcal{A}_\kappa \otimes Cl(3) \), that is, the symmetry algebra of the \( osp(1|2) \)-realisation linked to the group \( W = \mathbb{Z}_2 \times D_{2m} \) acting on the three-dimensional Euclidean space. A pair of ladder operators behaving...
nicely under the action of the double covering \( \tilde{W} \) of the group \( W \) was instrumental to this. As the construction was rather involved, only the case when the Clifford algebra had positive signature was considered, that is when the generators \( e_1, e_2, e_3 \) square to 1. The goal of this short contribution is to give the needed results to proceed to the same construction in the case when the Clifford algebra has negative signature, that is \( e_1, e_2, e_3 \) square to \(-1\). To help compare, the sign introduced is given as \( \varepsilon \in \{-1, +1\} \). We study thus here the algebra \( \mathfrak{A}_m^\varepsilon \subset \mathfrak{s}\mathfrak{k} \otimes \text{Cl}^\varepsilon(3) \). The complete classification of the finite-dimensional representations is long and would greatly exceed the allowed space, we refer the readers to [2] for its details. We believe this contribution could be of help for interested readers who want to translate our results, since both conventions for Clifford algebras coexist and the two lead to non-isomorphic real Clifford algebras; multiplication of the generators by \( i \) gives the correspondence for complex Clifford algebras.

In Section 2 we present the general result needed for the construction. Proposition 1 gives the commutation relations respected by the algebra, where a small sign change appears. Proposition 2 compares the Casimir of the \( \mathfrak{osp}(1|2) \) superalgebra with central elements of \( \mathfrak{A}_m^\varepsilon \), and two signs appear. As a consequence, the factorisation of the ladder operators changes slightly as shown in Proposition 5. The remaining steps of the construction of the finite-dimensional representations are then presented in Section 3.

2 The dihedral Dunkl–Dirac symmetry algebra

In this section we present the necessary definitions and results on the dihedral Dunkl–Dirac symmetry algebra. We refer the readers to [2, Sec. 2 and 3] for more details, bearing in mind that \( \varepsilon = +1 \) there.

We consider the Euclidean space \( \mathbb{R}^3 \) with coordinate vectors \( \xi_1, \xi_2, \xi_3 \) and its canonical bilinear form \( \langle -,- \rangle \). Let \( W = \mathbb{Z}_2 \times D_{2m} \). Its root system \( R \) is

\[
R = \{ \alpha_0 := (0,0,1), -\alpha_0, \alpha_j := (\sin(j \pi / m), -\cos(j \pi / m), 0) \mid 1 \leq j \leq 2m \}. \tag{1}
\]

The positive root system is \( R_+ = \{ \alpha_0, \alpha_1, \ldots, \alpha_m \} \) and the simple roots are given by \( \alpha_0, \alpha_1 \) and \( \alpha_m \). The related reflections \( \sigma_\alpha(x) := x - 2 \langle x, \alpha \rangle / \langle \alpha, \alpha \rangle \) are given in matrix form by

\[
\sigma_0 := \sigma_{\alpha_0} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \quad \sigma_j := \sigma_{\alpha_j} = \begin{pmatrix} \cos(2j \pi / m) & \sin(2j \pi / m) & 0 \\ -\sin(2j \pi / m) & \cos(2j \pi / m) & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{2}
\]

Let \( \kappa : R \to \mathbb{C} \) be a function invariant on the \( W \)-orbits. The Dunkl operators are

\[
\mathcal{D}_j f(x) := \partial_x f(x) + \sum_{\alpha \in R^+} \kappa(\alpha) \frac{f(x) - f(\sigma_\alpha(x))}{\langle x, \alpha \rangle} \langle \alpha, \xi_j \rangle. \tag{3}
\]
The dihedral Dunkl–Dirac symmetry algebra with negative Clifford signature

The Dunkl operators, the group algebra $\mathbb{C}[W]$ and the multiplication operators generate a faithful representation denoted $\mathcal{A}_\varepsilon$ of a rational Cherednik algebra.

Let $\varepsilon \in \{-1,+1\}$ be a sign and $\mathcal{C}^{\varepsilon}(3)$ be the Clifford algebra generated by the three anticommuting elements $e_1, e_2, e_3$ subject to

$$\{e_j, e_k\} = 2\varepsilon \delta_{jk}. \quad (4)$$

There is an $\mathfrak{osp}(1|2)$-realisation given by the Dunkl–Dirac operator $D$ and its dual symbol $\bar{x}$ in the tensor product $\mathcal{A}_\varepsilon \otimes \mathcal{C}^{\varepsilon}(3)$:

$$D = D_1 e_1 + D_2 e_2 + D_3 e_3, \quad \bar{x} = x_1 e_1 + x_2 e_2 + x_3 e_3. \quad (5)$$

We are interested in the elements of $\mathcal{A}_\varepsilon \otimes \mathcal{C}^{\varepsilon}(3)$ supercommuting with the $\mathfrak{osp}(1|2)$-realisation, obtained in previous work [1]. First, the following elements in $W \otimes \mathcal{C}^{\varepsilon}(3)$ anticommute with $D$ and $\bar{x}$:

$$\bar{\sigma}_\alpha = \sigma_\alpha \otimes \sum_{j=1}^3 \langle \alpha, \xi_j \rangle e_j. \quad (6)$$

They generate a group that is isomorphic to either one of the two possible central extensions of $W$ denoted by $W^\varepsilon$ [5]. The simple roots become $\bar{\sigma}_0 := \bar{\sigma}_{\alpha_0}, \bar{\sigma}_1 := \bar{\sigma}_{\alpha_1}, \bar{\sigma}_m := \bar{\sigma}_{\alpha_m}$ and they respect the following relations depending on the parity of $m$ and the value of $\varepsilon$:

$$\bar{\sigma}_j^2 = \varepsilon, \quad (\bar{\sigma}_0 \bar{\sigma}_m)^2 = -1, \quad (\bar{\sigma}_1 \bar{\sigma}_m)^m = (-1)^{m+1} \varepsilon^m. \quad (7)$$

The following linear combinations, called one-index symmetries, of $\mathbb{C}[W] \otimes \mathcal{C}^{\varepsilon}(3)$ are distinguished:

$$O_j = \sum_{k=0}^m \kappa(\alpha_k) \langle \alpha_k, \xi_j \rangle \bar{\sigma}_{\alpha_k} = \frac{\varepsilon}{2} \left( [D, x_i] - e_i \right) = \frac{\varepsilon}{2} \left( \sum_{k=1}^3 e_kD_kx_j - e_j \right). \quad (8)$$

Defining $L_{ij} := x_i D_j - x_j D_i$, the following elements, named the two-index symmetries, commute with $D$ and $\bar{x}$:

$$O_{ij} := L_{ij} + \frac{\varepsilon}{2} e_i e_j + O_i e_j - O_j e_i, \quad (9)$$

$$= L_{ij} + \frac{\varepsilon}{2} e_i e_j + e_i O_j - e_j O_i. \quad (10)$$

The final symmetry is named three-index symmetry and is given by

$$O_{123} = -\frac{\varepsilon}{2} e_1 e_2 e_3 - O_1 e_2 e_3 - O_2 e_3 e_1 - O_3 e_1 e_2 + O_1 e_2 e_3 + O_2 e_3 e_1, \quad (11)$$

$$= -\frac{\varepsilon}{2} e_1 e_2 e_3 - e_2 e_3 O_1 - e_3 e_1 O_2 - e_1 e_2 O_3 + e_3 O_1 + e_2 O_3 + e_1 O_{23}. \quad (12)$$
**Definition 1.** The dihedral Dunkl–Dirac symmetry algebra $\mathfrak{A}_m^\varepsilon$ is the associative subalgebra of $\mathfrak{osp}(1|2)\otimes Cl^F(3)$ generated by $O_{12}, O_{31}, O_{23}, O_{123}$ and the group algebra $\mathbb{C}[\tilde{W}^\varepsilon]$. It is the full centraliser of the $\mathfrak{osp}(1|2)$-realisation [6].

**Proposition 1.** The element $O_{123}$ commutes with every element of $\mathfrak{A}_m^\varepsilon$; the two-index symmetries respect

\[
\begin{align*}
[O_{12}, O_{31}] &= O_{23} + 2O_1O_{123} + \varepsilon [O_2, O_3], \\
[O_{23}, O_{12}] &= O_{31} + 2O_2O_{123} + \varepsilon [O_3, O_1], \\
[O_{31}, O_{23}] &= O_{12} + 2O_3O_{123} + \varepsilon [O_1, O_2],
\end{align*}
\]

and the elements of $\tilde{W}^\varepsilon$ interact as

\[
\begin{align*}
\tilde{\sigma}_0 O_{12} &= O_{12} \tilde{\sigma}_0, & \tilde{\sigma}_j O_{12} &= - O_{12} \tilde{\sigma}_j, \\
\tilde{\sigma}_0 O_{31} &= - O_{31} \tilde{\sigma}_0, & \tilde{\sigma}_j O_{31} &= (\cos(2j\pi/m)O_{31} + \sin(2j\pi/m)O_{23}) \tilde{\sigma}_j, \\
\tilde{\sigma}_0 O_{23} &= - O_{23} \tilde{\sigma}_0, & \tilde{\sigma}_j O_{23} &= (\cos(2j\pi/m)O_{31} + \sin(2j\pi/m)O_{23}) \tilde{\sigma}_j.
\end{align*}
\]

**Proof.** The relations (13) come from [1, Thm 3.12]. For (14), remark that it is equivalent to consider $\tilde{\sigma}_j L_{ij}$ by the definition (9) of $O_{ij}$ and that (6) of $\tilde{\sigma}_j$. Then only $\tilde{\sigma}_j O_{12}$ is not direct, and we get:

\[
\sigma_j L_{12} = \sigma_j(x_1 \mathcal{Q} - x_2 \mathcal{P}_1) = (\sin^2(2j\pi/m) + \cos^2(2j\pi/m))L_{21} \sigma_j = - L_{12} \sigma_j.
\]

Working out the remaining terms of (9) gives the rest. $\square$

We are interested in the representation theory of $\mathfrak{A}_m^\varepsilon$. The construction uses ladder operators, and their factorisations in turn follow from the next proposition.

**Proposition 2.** The three-index symmetry squares to

\[
O_{123}^2 = - \frac{\varepsilon}{4} + O_1^2 + O_2^2 + O_3^2 + \varepsilon(O_{12}^2 + O_{31}^2 + O_{23}^2).
\]

**Proof.** Express $O_{123}^2$ as the product of the two expressions (11) and (12)

\[
\begin{align*}
O_{123}^2 &= \left(\frac{-\varepsilon}{2} e_1 e_2 e_3 - O_{1} e_2 e_3 - O_2 e_3 e_1 - O_3 e_3 e_1 - O_{12} e_3 + O_{123} e_1 + O_{31} e_1 + O_{23} e_1\right) \\
&\quad \times \left(\frac{-\varepsilon}{2} e_1 e_2 e_3 - e_2 e_3 O_{1} - e_3 e_1 O_{2} - e_1 e_2 O_{3} + e_3 O_{12} + e_2 O_{31} + e_1 O_{23}\right) \\
&= - \frac{\varepsilon}{4} - O_1^2 - O_2^2 - O_3^2 + \varepsilon(O_{12}^2 + O_{31}^2 + O_{23}^2) + Q,
\end{align*}
\]

where $Q$ expresses the 42 remaining “cross terms”. We show now that $Q = 2(O_1^2 + O_2^2 + O_3^2)$. Replace in $Q$ all instances of $O_{ij}$ on the left with (9), and all instances on the right by (10). For example, the terms below produce $2(O_1^2 + O_2^2 + O_3^2)$ (the underlined term comes from the two underlined terms in the product).
The dihedral Dunkl–Dirac symmetry algebra with negative Clifford signature

\[ A = \varepsilon\left( (O_2e_1O_{12} - O_{12}e_1O_2) + (O_1e_3O_{31} - O_{31}e_3O_1) + (O_3e_2O_{23} - O_{23}e_2O_3) \right) \]

\[ = \varepsilon\left( O_2e_1L_{12} + \frac{1}{2}O_2e_2 + \varepsilon O_2^3 - O_2e_1e_2O_1 - L_{12}e_1O_2 + \frac{1}{2}e_2O_2 + O_1e_1e_2O_2 + \varepsilon O_2^5 \right. \]

\[ + O_1e_3L_{31} + \frac{1}{2}O_1e_1 + \varepsilon O_1^2 + O_1e_1e_3O_1 - L_{31}e_3O_1 + \frac{1}{2}e_1O_1 + O_3e_3e_1O_1 + \varepsilon O_1^2 \]

\[ + O_3e_2L_{23} + \frac{1}{2}O_2e_3 + \varepsilon O_2^2 + O_3e_3e_2O_2 - L_{23}e_3O_2 + \frac{1}{2}e_3O_2 + O_2e_2e_3O_3 + \varepsilon O_2^5 \right) \]

\[ = 2\varepsilon^2(O_1^2 + O_2^2 + O_3^2) + B, \quad \text{with } B \text{ the remaining part.} \]

After doing this procedure for all terms, and further simplifications, one reaches

\[ Q = 2(O_1^2 + O_2^2 + O_3^2) \]

\[ + \frac{\varepsilon}{2} \left( \frac{L_{12}e_1L_{12}(e_1e_1L_{31} - e_3e_1L_{23} + 2e_1O_1)}{+L_{31}e_3L_{23}(e_1e_1L_{12} - e_2e_1L_{31} + 2e_1O_1)} + \frac{\varepsilon}{2} \left( \frac{e_1e_1L_{31} - L_{23}e_3L_{31} + 2e_1O_1}{+e_1e_1L_{12} - e_2e_1L_{31} + 2e_1O_1} \right) \right). \]

The last line is zero. To prove this, replace the \( O_j \) by their last definition (8) in terms of commutators \( C_{kj} := [\partial_k, x_j] \) and apply the following identity \([1, \text{Thm } 2.5]\]

\[ L_{ij}L_{kl} + L_{kl}L_{ij} + L_{jk}L_{il} = L_{ij}C_{kl} + L_{kl}C_{ij} + L_{jk}C_{il}, \quad (17) \]

keeping in mind that \( L_{ii} = 0, L_{ij} = -L_{ji} \) and \( C_{ij} = C_{ji}. \)

This proposition yields in fact a correspondence between the Casimir of the Lie algebra \( \mathfrak{osp}(1|2) \) and a central element in the symmetry algebra. Similar statements hold for any reflection group in any dimension, see \([5]\).

The finite-dimensional representations are constructed via ladder operators. In the classical non-Dunkl case, the ladder operators for the \( \mathfrak{so}(3) \) algebra are given by the following linear combinations of the two-index symmetries:

\[ O_0 := -iO_{12}, \quad O_+ := iO_{31} + O_{23}, \quad O_- := iO_{31} - O_{23}. \quad (18) \]

For ease of notation, denote the following combination of one-index symmetries (note that they vanish when \( \kappa = 0 \)):

\[ T_0 := iO_3, \quad T_+ := O_1 + iO_2, \quad T_- := O_1 - iO_2. \quad (19) \]

**Proposition 3.** The commutation relations respected by \( O_0, O_+ \) and \( O_- \) are

\[ [O_0, O_+] = +O_+ + \{O_{123}, T_+\} + \varepsilon[T_0, T_+], \]

\[ [O_0, O_-] = -O_- + \{O_{123}, T_-\} - \varepsilon[T_0, T_-], \]

\[ [O_0, O_+] = 2O_0 - \{O_{123}, T_0\} + \varepsilon[T_+, T_-], \]

and those with \( T_0, T_+ \) and \( T_- \) are

\[ T_0O_0 = O_0T_0, \quad T_0O_+ = -O_+T_0, \quad T_0O_- = -O_-T_0, \]

\[ T_+O_0 = -O_0T_+, \quad T_+O_+ = -O_+T_+, \quad T_+O_- = O_-T_+, \]

\[ T_-O_0 = -O_0T_-, \quad T_-O_+ = -O_+T_-, \quad T_-O_- = O_-T_-. \quad (21) \]
Proof. Use the commutation relations of Proposition 1. □

In this new basis, the following expressions hold.

**Proposition 4.** The square of the three-index symmetry becomes

\[
O_{123}^2 = -\frac{\epsilon}{4} + T_+T_- - T_0^2 - \epsilon(O_0^2 - O_0 + O_+O_- + 2O_{123}T_0),
\]

\[
= -\frac{\epsilon}{4} + T_+T_- - T_0^2 - \epsilon(O_0^2 + O_0 - O_+O_- - 2O_{123}T_0).
\]

Furthermore, the following equations hold

\[
O_+O_- = \epsilon T_+T_- - (O_0 - 1/2)^2 - \epsilon(\epsilon O_{123} + T_0)^2,
\]

\[
O_-O_+ = \epsilon T_+T_- - (O_0 + 1/2)^2 - \epsilon(\epsilon O_{123} - T_0)^2.
\]

Proof. We prove (22) by directly rewriting from the definitions (18) and (19):

\[
O_{12}^2 = -O_0^2, \quad O_{31}^2 + O_{23}^2 = -O_+O_- + O_0 - 2O_{123}T_0 + \frac{\epsilon}{2}[T_+, T_-],
\]

\[
O_3^2 = T_0^2, \quad O_1^2 + O_2^2 = T_+T_- - \frac{1}{2}[T_+, T_-].
\]

Equation (23) is similar, and the expressions (24) and (25) follow directly. □

**Proposition 5.** The following operators

\[
L_+ := \frac{1}{2}\{O_0, O_+\} \quad \text{and} \quad L_- := \frac{1}{2}\{O_0, O_-\}
\]

are ladder operators with respect to \(O_0\) in the sense that

\[
[O_0, L_+] = +L_+, \quad [O_0, L_-] = -L_-,
\]

and the products of two of them admit the following factorisations

\[
L_+L_- = -((O_0 - 1/2)^2 + \epsilon(\epsilon O_{123} + T_0)^2)((O_0 - 1/2)^2 - \epsilon T_+T_-),
\]

\[
L_-L_+ = -((O_0 + 1/2)^2 + \epsilon(\epsilon O_{123} - T_0)^2)((O_0 + 1/2)^2 - \epsilon T_+T_-).
\]

Proof. That \(L_+\) and \(L_-\) are ladder operators comes from Proposition 3. [3]

\[
2|O_0, L_\pm| = |O_0, \{O_0, O_\pm\}| = \{O_0, |O_0, O_\pm|\}
\]

\[
= \{O_0, \pm O_\pm + \{O_{123}, T_\pm\} \pm \epsilon[T_0, T_\pm]\} = \pm\{O_0, O_\pm\} = 2L_\pm,
\]

where equation (14) was used in the second line. The proof of the factorisation is the same as [2] Prop 3.8 using the \(\epsilon\) variants of the commutation relations. □
3 Sketch of the finite-dimensional representations construction

Everything needed for the construction of the finite-dimensional representations is in place. Doing it would, however, greatly exceed the scope of this note. We give below a sketch of the steps needed and refer the readers to [2] for the details.

1. Any finite-dimensional $\mathfrak{g}m$-representation decomposes as a $\tilde{\mathbb{W}}^\varepsilon$-representation into a direct sum of spin irreducible $\tilde{\mathbb{W}}^\varepsilon$-representations by Maschke’s Theorem (the irreducible representations for these groups can be found in [2 Thm A.5]). Let $\tilde{\mathbb{W}}^\varepsilon_0$ be the subgroup of $\tilde{\mathbb{W}}^\varepsilon$ generated by elements commuting with $O_0$. The associative subalgebra of $\mathfrak{g}m$ generated by $O_0$, $L_\pm$, $O_{123}$ and $\tilde{\mathbb{W}}^\varepsilon_0$ has a triangular decomposition. Use this triangular decomposition and the ladder operators to give a basis of $O_0$- and $O_{123}$-eigenvectors for any irreducible $\mathfrak{g}m$-representation. (See [2, Lem. 4.3].)

2. Thus start from a general $O_0$- and $O_{123}$-eigenbasis. The elements $v^+_j$ and $v^-_j$ of this basis are obtained from multiple applications of the ladder operators on a first pair $v^+_0, v^-_0$. Use the two factorisations (28) and (29) to create equations $L_+ v^-_j = A(j) v^-_{j+1}$ and $L_- v^+_j = A(j) v^+_{j+1}$. The terms $A(j)$ will depend on the first $\tilde{\mathbb{W}}^\varepsilon$-representation, and on the eigenvalues of $O_{123}$ and $O_0$. Then irreducibility and the finite-dimension give conditions on $A(j)$. (See [2 (4.21)–(4.23)].)

3. Solve the system obtained for the values of the $O_{123}$- and $O_0$-eigenvalues keeping track of the conditions on $\kappa$. (See [2 (4.28)].)

4. Furthermore, the unitarity of the representations can be studied in the same fashion by looking at positivity constraints in the $A(j)$. (See [2 Sec. 3.3 and Lem. 4.4].)
