Abstract

Recently it is found that, due to Weyl anomaly, an external magnetic field can induce anomalous currents near a boundary. In this note, we study anomalous currents for complex scalars and Dirac fields in general dimensions. We develop a perturbation method to calculate Green’s function in the spacetime with boundaries. By applying this method, we obtain anomalous currents up to the linear order of magnetic fields in a half space and in a strip. To the best of our knowledge, the results for Dirac fermions and for strips are new. It is remarkable that, unlike the scalars and holographic BCFT, the anomalous currents of Dirac fields are independent of boundary conditions in general dimensions. Besides, the currents of Dirac fields are always larger than those of complex scalars. Finally, we find an exact formal expression of the anomalous current in a half space. The result is expressed in momentum integrals, which can be evaluated numerically. We find that the mass suppresses the anomalous currents as expected.

1 Introduction

The anomaly-induced transport is an important phenomenon, which has a wide range of applications [1]. The well-known examples include chiral magnetic effect (CME) [2–6] and chiral vortical effect (CVE) [7–13], which refer to the generation of currents due to an external magnetic field and the rotational motion in the charged fluid, respectively. It is interesting that the CME current is topologically protected and hence non-dissipative [1]. Similar to chiral anomaly, Weyl anomaly [14] can also induce anomalous currents in an external electromagnetic field [15–18]. See [19–26] for related works. It is remarkable that a similar mechanism leads to novel Fermi condensations when a background scalar field is turned on [27]. The scalar field can either be the Higgs field in a fundamental theory or the phonon in condensed
matter system.

On the other hand, the boundary effect of quantum field theory is another interesting phenomenon. Famous examples include Casimir effect \cite{28-30} and topological insulator \cite{31}. Recently, much attention has been drawn on boundary conformal field theory (BCFT) \cite{32,33} and its holographic dual (AdS/BCFT) \cite{34}. Please see \cite{19-22,35-57} for some of recent developments. It is interesting that a-Type anomalies of BCFT/dCFT can depend on marginal couplings \cite{57}.

In this paper, we investigate the anomalous current in a spacetime with a boundary. It is found in \cite{17,18} that, due to Weyl anomaly, an external electromagnetic field can induce an universal current

\[ J^\mu = -\frac{2\beta F^{\mu\nu} n_\nu}{x} + \ldots, \quad x \sim 0, \quad (1) \]

near the boundary, where $\beta$ is the beta function, $F^{\mu\nu}$ are the field strength, $x$ is the proper distance to the boundary, $n_i$ are the normal vectors and $\ldots$ denote higher order terms in $O(x)$. Note that there are boundary contributions to the current, which can cancel the ‘bulk’ divergence of (1) and make finite the total current \cite{17}. It is remarkable that the leading term of anomalous current (1) is universal in four dimensions. It is independent of the boundary conditions (BC), the temperature and the details of theories. What is more, it applies to not only conformal field theory but also the general quantum field theory \cite{17}. In higher dimensions, the anomalous current is expected to take the following form \cite{17}

\[ J_d^\mu = \frac{b_d}{x^{d-3}} F^{\mu\nu} n_\nu + \ldots, \quad x \sim 0, \quad (2) \]

where $b_d$ are central charges of Weyl anomaly and $d$ denote the dimensions. Note that $b_d$ depend on boundary conditions in dimensions other than four.

The previous works \cite{17,18} mainly discuss the general characteristics of anomalous currents. In particular, they focus on the region close to the boundary. In this note, we study more specific examples such as complex scalars and Dirac fermions, and try to explore the anomalous current in the full region of the system. By applying Green’s function method, we derive the anomalous currents for free theories up to the linear order of external magnetic field in a half space and in a strip. Our results agree with the work of \cite{58} for complex scalars in a half space. To the best of our knowledge, the anomalous currents for Dirac fermions and for strips are new. Our results are exact in the the size of strip, hence works well in the full region of a strip. We also obtain an exact formal expression of the anomalous current for complex scalars in a half space. The formal formula is expressed in momentum integrals, which can be evaluated numerically. Let us summarize the properties of anomalous currents for free theories below.

1. Unlike the holographic BCFT \cite{18} and complex scalars, the anomalous currents of Dirac fields are independent of BCs in general dimensions.
2. The anomalous currents of complex scalars have different signs for Dirichlet boundary condition (DBC) and Neumann boundary condition (NBC) in dimensions higher than four. See Figure. 2 for example.

3. The anomalous currents of Dirac fields are larger than those of complex scalars in four dimensions. See Figure. 3 for example.

4. The mass suppresses the anomalous current and the current approaches zero far away from the boundary. See Figure. 5 for example.

The paper is organized as follows. In sect. 2, we develop a perturbation method to calculate Green’s function. Our method includes only bulk integral, which is slightly different from that of [59, 60]. In sect. 3, by applying the perturbation method, we derive the anomalous currents for complex scalar and Dirac field in a half space in general dimensions. In sect. 4, we study the anomalous current in a strip. In sect. 5, we obtain a formal expression of the anomalous current in a half space. Finally, we conclude with discussions in sect. 6. We use conventions of [61] and the signature of metric is $(1, -1, ..., -1)$.

2 Green’s Function

Green’s function is a powerful tool to calculate expectation value of stress-energy tensors and currents near a boundary [59, 60]. Usually, Green’s function is expressed as a boundary integral for BCFT [59, 60]. Here we develop a slightly different approach where Green’s function includes only bulk integrals. Our approach has the advantage that the nth term of series of Green’s function is of order $O(B^n)$

$$G = \sum_{n=0}^{\infty} G_n, \quad G_n \sim O(B^n) \quad (3)$$

where $B$ denote the magnetic field or other perturbation parameters. As a result, to derive the leading term of anomalous currents of $O(B)$, we only need to calculate one term $G_1$ in the Green’s function. To illustrate our approach, let us take complex scalars and Dirac fields as examples below.

2.1 Complex scalar

Let us start with the action of free complex scalars in a curved spacetime

$$I = \int_M dx^d \sqrt{|g|} D_\nu \phi (D^\nu \phi)^*, \quad (4)$$
where $d$ is the dimension of spacetime and $D_\mu = \nabla_\mu - ieA_\mu$ is the covariant derivative. For simplicity, we set $e = 1$ in this paper. The Green function satisfies equation of motion (EOM)

$$D_\mu D_\mu G(x, x') = (\nabla_\mu \nabla_\mu + E)G(x, x') = \delta(x, x'), \quad (5)$$

where we take $E = (-2iA^\mu \nabla_\mu - i\nabla_\mu A_\mu - A^\mu A_\mu)$ as perturbations. One can impose either DBC

$$G(x, x')|_{\partial M} = 0, \quad (6)$$

or NBC

$$D_n G(x, x')|_{\partial M} = 0, \quad (7)$$

on the boundary $\partial M$. Here $n$ denotes the normal direction.

We split Green’s function into the background $G_0$ and a correction $G_c$

$$G = G_0 + G_c, \quad (8)$$

where $G_0$ obeys EOM

$$\nabla_\mu \nabla_\mu G_0(x, x') = \delta(x, x'), \quad (9)$$

together with either DBC

$$G_0|_{\partial M} = 0, \quad (10)$$

or NBC

$$\nabla_n G_0|_{\partial M} = 0. \quad (11)$$

Applying Green’s formula, we have

$$\int_M dx^d \sqrt{|g|} \left[ G_c(x', x) D_\mu D_\mu G(x, x'') - G_c(x', x) \tilde{D}_\mu^* \tilde{D}_\mu^* G(x, x'') \right]$$

$$= \int_{\partial M} dy^{d-1} \sqrt{|h|} \left[ G_c(x', x) D_n G(x, x'') - G_c(x', x) \tilde{D}_n^* \tilde{D}_n^* G(x, x'') \right] \quad (12)$$

where $\tilde{D}_\mu^* = \tilde{\nabla}_\mu + iA_\mu$ means acting on the left. We choose the gauge $A_n = 0$ so that $D_n = D_n^* = \nabla_n$ on the boundary. Imposing either DBC (6, 10) or NBC (7, 11), we find that the boundary terms of (12) vanish. From EOM (5, 9), we derive

$$G_c(x', x) \tilde{D}_\mu^* \tilde{D}_\mu^* = -G_0(x', x) \tilde{E}^*, \quad (13)$$

where

$$\tilde{E}^* = (2i\tilde{\nabla}_\mu A^\mu + i\nabla_\mu A_\mu - A^\mu A_\mu). \quad (14)$$
Substituting (5) and (13) into (12) and noting that the boundary terms vanishing due to BCs, we obtain a key formula

$$G_c(x', x'') = - \int_M dx^d \sqrt{|g|} \left[ G_0(x', x) \tilde{E}^*(x) G(x, x'') \right].$$  \hfill (15)

Unlike [59,60], there are only bulk integrals in $G_c$. From (15), we can calculate $G_c$ perturbatively

$$G_c(x', x'') = - \int_M dx^d \sqrt{|g|} G_0(x', x) \tilde{E}^*(x) G_0(x, x'')$$

$$+ \int_M dx^d \sqrt{|g|} \int_{M_1} dx^d_1 \sqrt{|g_1|} G_0(x', x) \tilde{E}^*(x) G_0(x, x_1) \tilde{E}^*(x_1) G_0(x_1, x'')$$

$$+ ...$$  \hfill (16)

where the nth line of (16) is of order $O(E^n)$.

### 2.2 Dirac field

Now let us turn to study Green’s function of Dirac fields. The action of free Dirac fields in a curved spacetime is given by

$$I = \int_M dx^d \sqrt{|g|} \bar{\Psi} i \gamma^\mu D_\mu \Psi,$$  \hfill (17)

where $\bar{\Psi} = \Psi^+ \gamma^0$ and $D_\mu = \nabla_\mu - i A_\mu$. Green’s function obeys EOM

$$i \gamma^\mu D_\mu S(x, x') = \delta(x, x'),$$  \hfill (18)

where $\delta(x, x') = \delta^d(x - x')/\sqrt{|g|}$. We impose bag boundary condition (BBC)

$$\Pi_- S(x, x')|_{\partial M} = 0,$$  \hfill (19)

where $\Pi_\pm = (1 \pm \chi)/2$ are projection operators and $\chi$ satisfy

$$\chi \gamma_n = -\gamma_n \bar{\chi}, \quad \chi \gamma_a = \gamma_a \bar{\chi}, \quad \chi^2 = \bar{\chi}^2 = 1,$$  \hfill (20)

where $\bar{\chi} = \gamma^0 \chi^+ \gamma^0$ and $n (a)$ denote the normal (tangent) directions. From BBC (19-20), we can derive

$$S(x'', x') \gamma_n S(x, x')|_{\partial M} = 0.$$  \hfill (21)

We split Green function into a background $S_0$ and a correction $S_c$

$$S = S_0 + S_c,$$  \hfill (22)
where $S_0$ obeys EOM

$$i\gamma^\mu \nabla_\mu S_0(x,x') = \delta(x,x'),$$

(23)

together with BBC

$$\Pi_- S_0(x,x')|_{\partial M} = 0.$$  

(24)

From (19,20,24), we have

$$S_A(x'',x)\gamma_\mu S_B(x,x')|_{\partial M} = 0.$$  

(25)

where $S_{A,B}$ denote $S, S_0, S_c$.

Applying Green’s formula for Dirac fields, we have

$$\int_M dx^d \sqrt{|g|} \left[ S_c(x',x)i\gamma^\mu (\nabla_\mu - iA_\mu)S(x,x'') + S_c(x',x)i\gamma^\mu (\nabla_\mu + iA_\mu)S(x,x'') \right]$$

$$= \int_{\partial M} dx^{d-1} \sqrt{|h|} \left[ S_c(x',x)i\gamma_\mu S(x,x'') \right].$$

(26)

Note that the boundary term of (26) vanishes due to (25). Applying EOM (18, 23), we derive

$$S_c(x',x)i\gamma^\mu (\nabla_\mu + iA_\mu) = S_0(x',x)\gamma^\mu A_\mu$$

(27)

Now (26) can be simplified as

$$S_c(x',x'') = -\int_M dx^d \sqrt{|g|} \left[ S_0(x',x)\gamma^\mu (x)A_\mu(x)S(x,x'') \right].$$

(28)

From (28), we can calculate $S_c$ perturbatively

$$S_c(x',x'') = -\int_M dx^d \sqrt{|g|} S_0(x',x)\gamma^\mu A_\mu(x)S_0(x,x'')$$

$$+ \int_M dx^d \sqrt{|g|} \int_{M_1} dx'^d \sqrt{|g_1|} S_0(x',x)\gamma^\mu(x)A_\mu(x)S_0(x,x_1)\gamma^\mu(x_1)A_\mu(x_1)S_0(x_1,x'')$$

$$+ \ldots$$

(29)

where the $n$th line of (29) is of order $O(A^n)$.

Now we finish the perturbative derivations of Green’s function for complex scalars (16) and Dirac fields (29).

3 Current in a half space

In this section we calculate the anomalous current for complex scalars and Dirac fields in a half space. For simplicity, we focus on the half space $x \geq 0$ with a constant magnetic field parallel to the boundary. We have $x^\mu = (t,x,y_a) = (t,x,y_1,\ldots,y_{d-2})$, $A_\mu = (0,0,Bx,0,\ldots,0)$ and $g_{\mu\nu} = \eta_{\mu\nu} = \text{diag}(1,-1,\ldots,-1)$. 

6
3.1 Complex scalar

Green’s function of the complex scalar is given by \[59\]

\[ G(x, x') = \langle \phi(x) \phi(x') \rangle > \]  

where \( T \) is the time-ordering symbol. The non-renormalized current is defined by

\[
\hat{J}_\mu(x) = \frac{\delta I_{eff}}{\sqrt{|g|} \delta A^\mu} = \lim_{x' \to x} (D_\mu - D_\mu^*) G(x, x')
\]  

which is divergent generally. Here \( I_{eff} \) denotes the effective action. To get the renormalized current \( \hat{J}_\mu \), one should subtract the reference current without boundaries

\[
\hat{J}_\mu(x) = \lim_{x' \to x} (D_\mu - D_\mu^*) (G(x, x') - \hat{G}(x, x'))
\]  

where \( \hat{G} \) is reference Green’s function in the spacetime without boundaries. By using (16), we can obtain \( G \) and \( \hat{G} \) as

\[
G(x', x''') = G_0(x', x''') + 2iB \int_0^\infty dx \int_0^\infty dt dy d^2 x \partial_y G_0(x, x) \phi(x) + O(B^2),
\]  

\[
\hat{G}(x', x''') = \hat{G}_0(x', x''') + 2iB \int_0^\infty dx \int_0^\infty dt dy d^2 x \partial_y \hat{G}_0(x, x) \phi(x) + O(B^2).
\]

Note that the integral regions of \( x \) are different for \( G \) and \( \hat{G} \). Here \( G_0 \) and \( \hat{G}_0 \) are Green’s functions without external magnetic fields

\[
G_0(x', x''') = \frac{\Gamma(d/2) - 1}{4\pi^{d/2}} \left( \frac{i}{[(x' - x'')^2 + (y'' - y'')^2 - (t' - t'')^2]^{1/2}} \right)^{d/2} + \chi \left( [(x' + x''')^2 + (y'' + y'')^2 - (t' - t'')^2]^{1/2} \right)^{d/2},
\]  

\[
\hat{G}_0(x', x''') = \frac{\Gamma(d/2) - 1}{4\pi^{d/2}} \left( \frac{i}{[(x' - x'')^2 + (y'' - y'')^2 - (t' - t'')^2]^{1/2}} \right)^{d/2},
\]

where \( \chi = -1 \) for DBC and \( \chi = 1 \) for NBC. One can check that \( G_0, (35) \) satisfy EOM (9) and BCs (10).

To do the integral along \( t \), it is more convenient to perform the Wick rotation \( t = -it_E \). Substituting (33, 36) into (32) and performing the Wick rotation, we get

\[
\hat{J}_{y_1} = \chi 2^{1-d} \pi^{-d/2} \Gamma\left( \frac{d}{2} - 1 \right) B x^{3-d} + B \int_0^\infty dx' \int_0^\infty dr (f_1 + \chi f_2) + O(B^2),
\]

where

\[
f_1 = \frac{(2 - d) r^{d-2} \Gamma\left( \frac{d}{2} - 1 \right)^2 x' ((d - 3)r^2 + (d - 1)(x + x')^2)}{4\pi^{(d+1)/2} \Gamma\left( \frac{d+1}{2} \right) \left( r^2 + (x' + x)^2 \right)^d}
\]  

\[
(38)
\]
\[ f_2 = \frac{x'(2-d)\pi^2 2^{d-2} \Gamma \left( \frac{d}{2} - 1 \right)}{4 \Gamma \left( \frac{d+1}{2} \right) \left( r^2 + (x-x')^2 \right)^{\frac{d+1}{2}}} \left[ (d-3)r^6 + (3d-7)r^4 \left( x^2 + x'^2 \right) \right. \]
\[ + r^2 \left( (3d-5)x^4 + (3d-5)x'^4 + 2(1-3d)x^2x'^2 \right) + (d-1) \left( x^2 - x'^2 \right)^2 \left( x^2 + x'^2 \right) \]  

(39)

Here \( r^2 = y_0^2 + r_E^2 \), \( x^2 = 1 \) and we have performed angle integrals above. After the radial integration, we get

\[
\int_0^\infty dr (f_1 + \chi f_2) = \begin{cases} 
\frac{2^{d-4} \pi^{d-2} \Gamma \left( \frac{d}{2} - 1 \right) x' (x')^{d-1} + \chi (x' + x)^{d-1}}{(1-d)(x')^{d-1}(x+x')^{d-1}}, & x' > x \\
\frac{2^{d-4} \pi^{d-2} \Gamma \left( \frac{d}{2} - 1 \right) x' (x')^{d-1} + \chi (x' + x)^{d-1}}{(1-d)(x+x)^{d-1}(x+x')^{d-1}}, & x' < x.
\end{cases} 
\]

(40)

Note that the integrals are different for \( x' > x \) and \( x' < x \). Substituting (40) into (37) and integrating along \( x' \), we finally obtain the anomalous current

\[ J_{y_1} = \pi^2 \Gamma \left( \frac{d}{2} - 1 \right) \frac{2^{1-d}}{2(d-3)(1-d)} \left( 2 - (d-4)(d-1) \chi \right) \frac{B}{x^{d-3}} + O(B^2), \]

(41)

which agree with results of \cite{58} derived by the heat-kernel method. Recall that \( \chi = 1 \) (\( \chi = -1 \)) for NBC (DBC). The other components of currents vanish. Some comments are in order. First, the anomalous current depends on BCs and have different sign for different BCs in dimensions other than four. Second, it is remarkable that the current is independent of BC in four dimensions

\[ J_{y_1}^{\mu} = 4 \sqrt{\frac{2}{\pi}} x \frac{B}{2^{d-2} \pi^{d-2} x} + O(B^2), \]

(42)

which agrees with the result \cite{17,18}. Note that \( J_{y_1}^{\mu} = -N_{y_1} \) in our conventions. Third, in the above calculations, we have assumed \( d > 3 \). After the analytical extension, the result (41) works well for DBC in two and three dimensions. However, this is not the case for NBC. In dimensions lower than four, we have

\[ J_{y_1}^{\mu} = \delta_{y_1}^{\mu} \left( \frac{B}{16\pi} + O(B^2), \right) \]

\[ \frac{B}{2^{d-2} \pi^{d-2} x} + \frac{B(4 \log(x) + 2\gamma - 1 + \log(16\pi^2))}{2\pi} + O(d - 2, B^2), \]  

DBC

\[ J_{y_1}^{\mu} = \delta_{y_1}^{\mu} \left( \frac{B}{16\pi} + O(B^2), \right) \]

\[ \frac{B}{4\pi(d-3)} - \frac{B(4 \log(x) + 3 + \log(16\pi^2) - 2\psi(1) \log(\frac{1}{x}))}{16\pi} + O(d - 3, B^2), \]  

NBC

(43)

(44)

where \( \gamma \) is Euler Gamma function and \( \psi \) is the PolyGamma function. One may regularize the currents for NBC by

\[ J_{y_1}^{\mu}(d = 2 + \epsilon) + J_{y_1}^{\mu}(d = 2 - \epsilon) \]

\[ J_{y_1}^{\mu}(d = 3 + \epsilon) + J_{y_1}^{\mu}(d = 3 - \epsilon) \]

(45)

(46)

In this way, the divergences of (41) cancel and we get finite currents for NBC in two and three dimensions. We leave a careful discussion of the lower-dimensional currents to future work.
3.2 Dirac field

Let us go on to discuss the anomalous current for Dirac field. Similarly, we have $A_\mu = (0, 0, Bx, 0, ..., 0)$. Without loss of generality, we choose the chiral bag boundary condition

$$\Pi_- \Psi|_{\partial M} = \frac{1 + i e^{i \theta \gamma_5} \gamma_\nu}{2} \Psi|_{\partial M} = 0,$$  \hspace{1cm} (47)

where $\theta$ is a constant and $n$ denotes the normal direction, i.e., $\gamma^n = \gamma^1$. Equivalently, we have chosen

$$\chi = -i e^{i \theta \gamma_5} \gamma_\nu.$$

One can check that it satisfies the conditions (20). Note that (47) reduces to the usual bag boundary condition when $\theta = 0, \pi$.

The Feynman Green function of Dirac field is given by [61]

$$S(x, x') = -i < T \Psi(x) \Psi(x') >,$$ \hspace{1cm} (49)

from which one can derive the current

$$J^\mu = -i \lim_{x' \to x} \text{Tr} \left[ \gamma^\mu (S(x, x') - \tilde{S}(x, x')) \right],$$ \hspace{1cm} (50)

where we have subtracted the reference Green function $\tilde{S}$ without boundaries. From the key formula (29), we get

$$S(x', x'') = S_0(x', x'') - B \int_0^\infty dx \int_{-\infty}^{\infty} dt dy y^2 S_0(x', x) \gamma^2 x S_0(x, x'') + O(B^2),$$ \hspace{1cm} (51)

$$\tilde{S}(x', x'') = \tilde{S}_0(x', x'') - B \int_0^\infty dx \int_{-\infty}^{\infty} dt dy y^2 \tilde{S}_0(x', x) \gamma^2 x \tilde{S}_0(x, x'') + O(B^2).$$ \hspace{1cm} (52)

where $\gamma^2 = \gamma^n$ and

$$S_0(x', x'') = \frac{(d - 2) \Gamma \left( \frac{d - 2}{2} \right)}{4 \pi^{\frac{d}{2}}} \left( \frac{\gamma^0 (t' - t'') - \gamma^1 (x' - x'')}{(x' - x'')^2 + (y'_a - y''_a)^2 + (t' - t'')^2} \right)$$

$$+ \gamma^0 (t' - t'') - \gamma^1 (x' - x'') - \gamma^a (y'_a - y''_a),$$ \hspace{1cm} (53)

$$\tilde{S}_0(x', x'') = \frac{(d - 2) \Gamma \left( \frac{d - 2}{2} \right)}{4 \pi^{\frac{d}{2}}} \left( \frac{\gamma^0 (t' - t'') - \gamma^1 (x' - x'')}{(x' - x'')^2 + (y'_a - y''_a)^2 + (t' - t'')^2} \right).$$ \hspace{1cm} (54)

Substituting (51, 54) into (50) and performing Wick rotation, we derive

$$J^\mu = B \int_0^\infty dx' \int_0^\infty dr \frac{r^{d-2} \Gamma \left( \frac{d}{2} \right)^2 x' 2^{d-1}}{\pi^{\frac{d+1}{2}} \Gamma \left( \frac{d+1}{2} \right)} \left( (d-3)r^2 + (d-1)(x' + x)^2 \right) + O(B^2),$$ \hspace{1cm} (55)

9
where \([\ ]\) denotes the integer part. After the integrals along \(x'\) and \(r\), we obtain the anomalous current in a half space for Dirac fields

\[
J^\mu = \delta^\mu_{y_1} \pi^{-\frac{d}{2}} \Gamma \left( \frac{d}{2} \right) 2^\left[\frac{d}{2}\right]-d+1 \frac{B}{x^{d-3}} + O(B^2). \tag{56}
\]

To the best of our knowledge, this result is new. It is remarkable that the leading term of current (56) is independent of choices of BCs (47), that different chiral angles \(\theta\) yield the same current. This is quite different from the currents of complex scalars (41) and holographic BCFT [18] which depend on BCs. To end this section, let us list the currents for Dirac fermions (56) in four dimensions

\[
J^\mu_{4d} = \delta^\mu_{y_1} \frac{B}{6\pi^2 x} + O(B^2), \tag{57}
\]
in two dimensions

\[
J^\mu_{2d} = -\delta^\mu_{y_1} \frac{B x}{\pi} + O(B^2), \tag{58}
\]
and in three dimensions

\[
J^\mu_{3d} = \delta^\mu_{y_1} \left( \frac{B}{8\pi(d-3)} - \frac{B \left( 2 \log(x) + 1 + \log(2\pi) - \psi(0) \left( \frac{3}{2} \right) \right)}{16\pi} \right) + O((d-3)^1, B^2). \tag{59}
\]

It is interesting that (56) works well in two dimensions. Note that since there is no magnetic field in two dimensions, \(B\) should be understood as electric field and \(J^\mu_{2d}\) should be understood as charge density in (58). Similar to the case of scalar, the formula (56) does not work well in three dimensions. One can regularize the 3d current in the same way as (46). We leave a careful study of the 3d current to future work.

4 Current in a strip

We have investigated the anomalous current in a half space \(0 \leq x\). Now let us go on to study the anomalous current in a strip \(0 \leq x \leq L\). For simplicity, we mainly focus on four dimensions in this section.

4.1 Complex scalar

Let us first discuss the complex scalar. The approach is similar to that of sect. 3.1. Applying (16), we get Green’s function

\[
G(x', x'') = G_0(x', x'') + 2iB \int_0^L dx \int_{-\infty}^{\infty} dt dy d^{d-2} G_0(x', x) x \frac{\partial}{\partial y_1} G_0(x, x'') + O(B^2), \tag{60}
\]
with the background one
\[ G_0(x', x'') = \frac{\Gamma(\frac{d}{2} - 1)}{4\pi^{d/2}} \sum_{m = -\infty}^{\infty} \left( \frac{i}{[(x' - x'')^2 + (y'_a - y''_a)^2 - (t' - t'')^2]^{\frac{d-2}{2}}} + \chi \frac{i}{[(x' + x'')^2 + (y'_a - y''_a)^2 - (t' + t'')^2]^{\frac{d-2}{2}}} \right), \] (61)

which can be derived by the mirror method. Note that there are infinite images for two parallel mirrors, and each image corresponds to one \( m \) of \( \bar{g} \). The reference Green’s functions are still given by \( 34, 36 \). To simplify the deduction, we rewrite the reference Green’s function \( 34 \) as
\[ \bar{G}(x', x'') = G_0(x', x'') + O(B^2) \]

where \( G_0 \) is given by \( 36 \). Now let us focus on four dimensions \( d = 4 \). Substituting \( 60, 61, 62 \) into \( 32 \) and performing Wick rotation, we get
\[ J_{y_1} = \sum_{m \neq 0} \frac{Bx}{8\pi^2 m^2 L^2} + \sum_{m = -\infty}^{\infty} \frac{\chi Bx}{8\pi^2 (Lm + x)^2} + B \int_{-\infty}^{L} dx' \int_{-\infty}^{\infty} dt dy dy dy dy dy dy dy dy dy \ dx (g_1 + g_2) + O(B^2), \] (63)

where
\[ g_1 = \sum_{m = -\infty}^{\infty} \frac{r^2 (Lm + x') \left( 3 (Lm + x' - x)^2 + r^2 \right)}{3\pi^3 \left( (Lm + x' - x)^2 + r^2 \right)^4} \] (64)

\[ g_2 = \frac{r^2 x'}{3\pi^3} \sum_{m_1, m_2 = -\infty}^{\infty} \left[ -2r^2 \left( \frac{\chi}{(A_1^2 + r^2)^2} + \frac{1}{(A_2^2 + r^2)^2} \right) \left( \frac{\chi}{(B_1^2 + r^2)^2} + \frac{1}{(B_2^2 + r^2)^2} \right) + 4r^2 \left( \frac{\chi}{(A_1^2 + r^2)^3} + \frac{1}{(A_2^2 + r^2)^3} \right) - \frac{3\chi}{(A_1^2 + r^2)^2} - \frac{3}{(A_2^2 + r^2)^2} \right] \] (65)

with \( A_1 = 2Lm_1 + x + x', A_2 = 2Lm_1 + x - x', B_1 = 2Lm_2 + x + x' \) and \( B_2 = 2Lm_2 - x + x' \).

The first two terms of \( 63 \) are due to the leading term of Green’s function \( (G_0 - \bar{G}_0) \). After the sum, they yield
\[ j_1 = \frac{Bx (3\chi \csc^2 \left( \frac{\pi}{2} x' \right) + 1)}{24L^2}. \] (66)
Let us go on to consider the integral of \( g \). Performing the \( r \) integral, we get
\[
\int_0^L dx' \int_0^\infty dr g_1 = \sum_{m=-\infty}^{\infty} \int_0^L dx' \frac{x' + Lm}{24\pi^2|x'|^3},
\] (67)
where \( |\cdot| \) denotes the absolute value. Thus one needs to discuss the cases \( m \geq 1 \), \( m \leq -1 \) and \( m = 0 \), respectively. After some calculations, we derive the current for \( m \neq 0 \)
\[
j_2 = -\frac{B \left( L^2 - 4Lx + 2x^2 \right)}{48\pi^2x(L-x)^2}. \] (68)
As for the case \( m = 0 \), the integral (67) is divergent. However, the divergence can be canceled by the integral of \( g_2 \) with \( m_1 = m_2 = 0 \). Combining together the integrals of \( g_1 \) with \( m = 0 \) and \( g_2 \) with \( m_1 = m_2 = 0 \), we get a finite current
\[
j_3 = -\frac{B \left( L^3(6\chi + 1) + 8L^2\chi x - 2L\chi x^2 - 4\chi x^3 \right)}{48\pi^2Lx(L+x)^2}. \] (69)
Now let us turn to the most complicated parts, the contributions from \( g_2 \). After the radial integration, we have
\[
\int_0^{\infty} dr g_2 = -\frac{x'}{3\pi^2} \sum_{m_1,m_2=-\infty}^{\infty} \left( \frac{1}{(|A_1| + |B_1|)^3} + \frac{1}{(|A_2| + |B_2|)^3} + \frac{\chi}{(|A_1| + |A_2|)^3} + \frac{\chi}{(|A_2| + |B_1|)^3} \right). \] (70)
One should discuss cases \( m_1 \geq 1, m_1 \leq -1, m_1 = 0 \) and \( m_2 \geq 1, m_2 \leq -1, m_2 = 0 \), respectively. We have already considered the case \( m_1 = m_2 = 0 \) in (69). The other eight cases contribute a current
\[
\begin{align*}
j_4 &= -\frac{B \left( 3\pi Lx \left( L^2 - x^2 \right)^2 \cot \left( \frac{\pi x}{2} \right) + \pi^2 Lx^5 + \pi^2 x^6 \right)}{72(\pi^2 L^2 x(L-x)^2(L+x)^2)} \\
&- \frac{B \left( -3L^6 + (6 + \pi^2) L^4 x + (6 + \pi^2) L^4 x^2 - 2\pi^2 L^3 x^3 - (3 + 2\pi^2) L^2 x^4 \right)}{72(\pi^2 L^2 x(L-x)^2(L+x)^2)} \\
&+ \frac{B \chi \left( LL(3L-2x) - \pi^2 x(L+x) \csc^2 \left( \frac{\pi x}{2} \right) - \pi x \cot \left( \frac{\pi x}{2} \right) \left( L^2 - \pi^2 x(L-x) \csc^2 \left( \frac{\pi x}{2} \right) \right) \right)}{24\pi^2 L^3 x}.
\end{align*}
\] (71)
In the above derivations, we first do the \( x' \) integral and then the sums for \( m_1 \) and \( m_2 \). Fortunately, the sum takes a special form \( \sum_{m_1,m_2=\pm 1} f(m_1 + m_2) \), which can be transformed into only one sum \( \sum_{m=2}(m-1)f(m) \). From (66, 68, 69, 71), we finally obtain the anomalous current for complex scalars in a strip
\[
J^\mu = B \frac{3 \cot \left( \frac{\pi x}{2} \right) \left( L^2(\chi + 1) + \pi^2 \chi x(L-x) \csc^2 \left( \frac{\pi x}{2} \right) \right) + \pi L(L-2x) \left( 3\chi \csc^2 \left( \frac{\pi x}{2} \right) + 1 \right)}{72\pi L^3} + O(B^2)
\] (72)
Figure 1: Anomalous current for scalars in a strip for DBC (blue line) and NBC (yellow line) in four dimensions.

Note that we have $J^{y_1} = -J_{y_1} = -(j_1 + j_2 + j_3 + j_4)$ and the other components of currents vanish. Since the magnetic field is a constant in the strip, the current is expected to be antisymmetric, i.e., $J^{y_1}(x) = -J^{y_1}(L - x)$. This is indeed the case of (72), which is a strong support of our results. Besides, the above currents have the correct limit (42) near the boundary

$$J^{y_1} \sim \begin{cases} 
\frac{B}{24\pi^2}x, & \frac{x}{L} \to 0 \\
\frac{B}{24\pi^2(x-L)}, & \frac{L-x}{L} \to 0,
\end{cases}$$

for both DBC $\chi = -1$ and NBC $\chi = 1$. This is also a test of our calculations. For the convenience of readers, let us draw a figure for the anomalous current in a strip. Without loss of generality, we set $B = L = 1$. As showed in figure 1, the current of NBC is larger than the one of DBC.

It is straightforward to generalize the above discussions to higher dimensions. Unfortunately, we do not find a general formula. Instead, we calculate them case by case. Please see below for some examples

$$J^{y_1}_{5d} = \frac{-B}{1024\pi^2L^4x^4}\left[6L^4\chi(L-x)(L + 3x) - 24Lx^4\zeta(3)(L - 2x) + 2\pi^2x^4(Lx - 2\pi^2\chi x^2)\csc^2\left(\frac{\pi x}{L}\right) + 2\pi^2x^4\csc^2\left(\frac{\pi x}{L}\right) \left(L^2(2\pi^2\chi + \chi - 2) + 3\pi^2\chi(x^2 - L^2)\csc^2\left(\frac{\pi x}{L}\right) + 2\pi L(\chi + 1) x \cot\left(\frac{\pi x}{L}\right)\right) + x^4\left(2L(\chi + 4) - x\right)\psi^{(1)}\left(1 - \frac{x}{L}\right) - 2L(3L\chi + x)\psi^{(1)}\left(\frac{x}{L}\right) + 2L(3L\chi - 5\chi x + x)\psi^{(2)}\left(\frac{x}{L}\right)\right) + x^4\left(\chi(L - x)^2\psi^{(3)}\left(1 - \frac{x}{L}\right) + \chi(L + 3x)(L - x)\psi^{(3)}\left(\frac{L + x}{L}\right) + 2L(3L\chi - 7\chi x - x)\psi^{(2)}\left(1 - \frac{x}{L}\right)\right],$$

(74)
Figure 2: The left (right) figure denotes 5d (6d) anomalous current for complex scalars in a
strip. Blue line is for DBC and yellow line is for NBC.

\[
J^\chi_{\alpha d} = \frac{-B}{28800\pi^3 L^5 x^4} \left[ 360L^5 \chi(L - x) - 8\pi^4 L x^4 (L - 2x) \\
+ 30\pi^3 L x^4 \csc^2 \left( \frac{\pi x}{L} \right) \left( (3L - x) \cot \left( \frac{\pi x}{L} \right) - 4\pi \chi(L - 2x) \left( 3 \csc^2 \left( \frac{\pi x}{L} \right) - 2 \right) \right) \\
+ 15L x^4 (-2L \chi - 5L + x) \psi^{(2)} \left( 1 - \frac{x}{L} \right) + 15L x^4 (L(2\chi + 5) - x) \psi^{(2)} \left( \frac{x}{L} \right) \\
+ 15\chi x^5 (L - x) \left( \psi^{(4)} \left( 1 - \frac{x}{L} \right) - \psi^{(4)} \left( \frac{L + x}{L} \right) \right) \right],
\]

where \( \psi \) denotes the PolyGamma function. It is interesting that DBC \( \chi = -1 \) and NBC
\( \chi = 1 \) yield different directions of currents in dimensions higher than four. See Figure 2 for
example.

4.2 Dirac field

In this subsection, let us investigate the anomalous current of Dirac field in a strip. For
simplicity, we mainly focus on four dimensions. By applying the key formula (29), we get
Green’s function for Dirac field

\[
S(x', x'') = S_0(x', x'') - B \int_0^L dx \int_{-\infty}^{\infty} dy \gamma^2 x S_0(x, x'') + O(B^2),
\]

where

\[
S_0(x', x'') = \sum_{m = -\infty}^{\infty} \frac{(d-2)\Gamma \left( \frac{d-2}{2} \right)}{4\pi^\frac{d}{2}} \left( \gamma^0(t' - t") - \gamma^1(2mL + x' - x'\prime) - \gamma^a(y'_a - y''_a) \right) \]

\[
\left( \frac{(2mL + x' - x'\prime)^2 + (y'_a - y''_a)^2 - (t' - t'\prime)^2}{2} \right) \]

\[
+ \chi \gamma^0(t' - t") - \gamma^1(-2mL - x' - x'\prime) - \gamma^a(y'_a - y''_a) \]

\[
\left( \frac{(2mL + x' + x'\prime)^2 + (y'_a - y''_a)^2 - (t' - t'\prime)^2}{2} \right) \right)
\]

\]

\]

\]

\]

\]
Substituting \(76\) into \(50\), we get the renormalized current

\[
J^{y_1} = B \int_0^L dx' \int_0^\infty dr \left(h_1 + h_2\right) + O(B^2),
\]

where

\[
h_1 = - \sum_{m=-\infty}^{\infty} \frac{4r^2(Lm + x') \left(3 (Lm + x' - x)^2 + r^2\right)}{3\pi^3 \left((Lm + x' - x)^2 + r^2\right)^4},
\]

\[
h_2 = \sum_{m_1,m_2=-\infty}^{\infty} \frac{4r^2x'}{3\pi^3} \left(\frac{3A_1B_1 + r^2}{(A_1^2 + r^2) \left(B_1^2 + r^2\right)^2} + \frac{r^2 - 3A_2B_2}{(A_2^2 + r^2) \left(B_2^2 + r^2\right)^2}\right)
\]

Recall that \(A_1 = 2Lm_1 + x + x', A_2 = 2Lm_1 + x - x', B_1 = 2Lm_2 + x + x'\) and \(B_2 = 2Lm_2 - x + x'\).

Following the approaches of sect. 3.1, we can derive the current. Since the calculations are similar to those of sect. 3.1, we do not repeat them here. We obtain

\[
J^{y_1} = \delta^{y_1}_y B \left(6L \cot \left(\frac{\pi x}{L}\right) - \pi L + 2\pi x\right) + O(B^2),
\]

which obeys the relation \(J^{y_1}(x) = -J^{y_1}(L - x)\) and reduces to the current \(57\) in a half space in the near-boundary limit

\[
J^{y_1} \sim \begin{cases} B & \frac{x}{L} \to 0, \\ \frac{B}{6\pi^2} & \frac{x}{L} \to 0. \end{cases}
\]

Similar to the case in a half space, the current \(81\) in a strip is independent of BCs \(47\) too.

To compare with the currents of scalars, let us draw a figure. From Figure 3, we notice that the current of Dirac field is always larger than those of scalars.

The generalizations to higher dimensions are straightforward. Following the above approach, we get anomalous currents for Dirac fields

\[
J^{y_1}_{5d} = \frac{3}{128\pi^2} \left(-2\zeta(3)(L - 2x) - L\psi^{(1)}(2 - \frac{x}{L}) + L\psi^{(1)}\left(\frac{x}{L}\right) - \frac{1}{(L - x)^2}\right) B + O(B^2),
\]

in five dimensions and

\[
J^{y_1}_{6d} = \frac{30L \cot \left(\frac{\pi x}{L}\right) \csc^2 \left(\frac{\pi x}{L}\right) - \pi L + 2\pi x}{900L^4} B + O(B^2).
\]

in six dimensions. Similar to the 4d case, currents of Dirac fields are independent of BCs \(47\) in higher dimensions. Besides, near the boundary, the currents become larger as the dimensions increase. See Figure 4 for example.

In summary, we have obtained the anomalous currents for complex scalars and Dirac fields in a strip. Our results are exact in the size of strip \(L\). In other words, we have got the anomalous currents beyond the near-boundary regions of \(18\).
5 Non-perturbative results

In previous sections, we focus on the anomalous current at the linear order of $O(B)$. In this section, we try to derive the current exactly in the magnetic field $B$. For simplicity, we focus on the complex scalar in a half space with a constant magnetic field $A_\mu = (0, 0, Bx, 0, ..., 0)$. We get a formal expression of currents which can be evaluated numerically.

Recall that Green’s function obeys EOM

$$[D^\mu D_\mu + m^2] G(x, x') = \delta^{(d)}(x, x'),$$

where $m$ is the mass. Performing Fourier transform for the tangential coordinates,

$$G = \int \frac{dk_\| d^{-1}}{(2\pi)^d-1} \tilde{G}(k) e^{-ik_\| \Delta x_\|}$$

we can rewrite (85) as

$$[-\partial^2_x + (m^2 + k_\|^2) - 2Bxk_1 + B^2x^2] \tilde{G} = \delta(x - x').$$

Here $k_1 = k_y, \Delta x_\| = k^\| (t - t') - k^a (y_a - y'_a)$ and $k_\|^2 = k^2 - k_0^2$. We split Green’s function $\tilde{G}$ into the one in free space and a correction due to the boundary

$$\tilde{G} = G_{\text{free}} + G_{\text{bdy}},$$

where $G_{\text{free}}$ is given by 

$$G_{\text{free}} = \begin{cases} \sqrt{\frac{1}{4\pi B}} \Gamma(\lambda_k) D_{-\lambda_k} \left( \sqrt{2} \left( \bar{x} - \bar{k}_1 \right) \right) D_{-\lambda_k} \left( \sqrt{2} \left( \bar{k}_1 - \bar{x} \right) \right), & x > x', \\ \sqrt{\frac{1}{4\pi B}} \Gamma(\lambda_k) D_{-\lambda_k} \left( \sqrt{2} \left( \bar{k}_1 - \bar{x} \right) \right) D_{-\lambda_k} \left( \sqrt{2} \left( \bar{x}' - \bar{k}_1 \right) \right), & x < x'. \end{cases}$$
Here $D$ denotes the parabolic cylinder function, $\lambda_k = (B + m^2 + k^2 - \bar{k}^2)/(2B)$, $\bar{k}_1 = k_1/\sqrt{B}$ and $\bar{x} = \sqrt{B}x$. Note that our convention of Fourier transform (86) is different from that of [60]. As a result, $G_{free}$ [59] differs by a factor $2\pi$ from the one of [60]. Imposing BCs (6), we solve the corrections to Green’s function

$$G_{bdy} = \frac{-\Gamma(\lambda_k)}{2\pi^{1/2}\sqrt{B}D_{-\lambda_k}} \left(D_{-\lambda_k} \left(\sqrt{2}(\bar{x} - \bar{k}_1)\right) D_{-\lambda_b} \left(\sqrt{2}(\bar{x}' - \bar{k}_1)\right)\right)$$ (90)

for DBC and

$$G_{bdy} = \frac{\Gamma(\lambda_k)}{2\pi^{1/2}\sqrt{B}D_{-\lambda_k}} \left(D_{-\lambda_k} \left(\sqrt{2}(\bar{x} - \bar{k}_1)\right) D_{-\lambda_k} \left(\sqrt{2}(\bar{x}' - \bar{k}_1)\right)\right)$$ (91)

for NBC. (90) for DBC agrees with [60] and (91) for NBC is a new result.

Now we are ready to derive the anomalous current. Substituting (86,90,91) into (32) and performing the Wick rotation $k^0 \rightarrow ik_E$ [64], we get the renormalized current

$$J_{yi} = \int_{-\infty}^{\infty} dp^{d-2}dk_1(\bar{x} - \bar{k}_1) \Gamma(\lambda_p) D_{-\lambda_p} \left(\sqrt{2}\bar{k}_1\right) D_{-\lambda_p} \left(\sqrt{2}(\bar{x} - \bar{k}_1)\right)$$ (92)

for DBC and

$$J_{yi} = -\int_{-\infty}^{\infty} dp^{d-2}dk_1(\bar{x} - \bar{k}_1) \Gamma(\lambda_p) \left(D_{-\lambda_p} \left(\sqrt{2}\bar{k}_1\right) - \bar{k}_1 D_{-\lambda_p} \left(\sqrt{2}\bar{k}_1\right)\right)$$
$$\times D_{-\lambda_p} \left(\sqrt{2}(\bar{x} - \bar{k}_1)\right)$$ (93)

for NBC. Recall that $J_{yi} = -J_{yi}$, $\lambda_p = (B + m^2 + p^2)/(2B)$, $\bar{k}_1 = k_1/\sqrt{B}$ and $\bar{x} = \sqrt{B}x$. In principle, the formal expressions (92,93) can be evaluated numerically. Let us take $d = 2$ as
an example, where the $p$ integral disappears, which can simplify calculations greatly. Note
that, for $d = 2$, $B$ of (92, 93) should be understood as the electric field, and $J_y$ should be
understood as the charge density. The results are shown in Figure 5, which implies that the
mass suppresses the current and the current approaches zero far away from the boundary.
These are the expected behaviors. Note that the numerical integration does not work well
near the boundary $x \sim 0$. In the near-boundary region, we can obtain the anomalous current
by using methods of sect. 3.1. See (43)(45) for example.

6 Conclusions and Discussions

In this paper, we have investigated the anomalous current for free theories in the spacetime
with boundaries. In a half space, we get the anomalous current at the linear order of magnetic
fields in general dimensions. The currents of scalars agree with those in the literature. And
the currents for Dirac field are new. Our results work well in the region close to the boundary,
i.e., $Bx^2 < 1$. We also obtain the anomalous currents in a strip. The currents are of the linear
order of magnetic field $B$ and exact in the size of strip $L$. This means that our results apply
to the full region of a strip, as long as the magnetic field is small $BL^2 < 1$. It is remarkable
that, unlike the scalar and holographic BCFT, the anomalous currents of free Dirac fields
are independent of boundary conditions in general dimensions. It should be mentioned that,
although we focus on the constant magnetic field in this paper, our approaches apply to
arbitrary electromagnetic fields as well. Finally, we derive a formal expression of anomalous
current for complex scalars in a half space. The numerical results imply that the mass
suppresses the anomalous currents. In this paper, we mainly focus on dimensions higher than
three. It is interesting to study carefully the cases in two and three dimensions. Besides, it
is also interesting to study the effect of temperature and the anomalous current with other
shapes of boundaries such as cylinders and balls. We hope we could address these problem
in future.
