The Particle in a Box
Warrants an Examination

Abstract

The particle in a box is a simple model that has a classical Hamiltonian $H = \frac{p^{2}}{2m}$ (using $2m = 1$), with a limited coordinate space, $-b < q < b$, where $0 < b < \infty$. Using canonical quantization, this example has been fully studied thanks to its simplicity, and it is a common example for beginners to understand. Despite its repeated analysis, there is a feature that puts the past results into question. In addition to pointing out the quantization issue, the procedures of affine quantization can lead to a proper quantization that necessarily points toward more complicated eigenfunctions and eigenvalues, which deserve to be solved.

1 A Standard Quantization of the Particle in a Box

The basic operators of canonical quantization (CQ), namely $P$ and $Q$, have appropriate representations that range over entire real values, which leads both operators to being self-adjoint, i.e., $P^\dagger = P$ and $Q^\dagger = Q$. These operators admit a Schrödinger representation, e.g., $P \rightarrow -i\hbar (d/dx)$ and $Q \rightarrow x$, with $-\infty < x < \infty$.

∗klauder@ufl.edu
Since our story takes place entirely in the interval \(-b < x < b\), we seek the solutions of
\[
-h^2 \left( \frac{d^2 \phi(x)}{dx^2} \right) = E \phi(x) \tag{1}
\]
with the requirement \(\phi(-b) = \phi(b) = 0\) to match the fact that \(\phi(x) = 0\) for all of \(x \leq -b\) and \(x \geq b\), thanks to ‘implicit infinite walls’. This connection at \(x = \pm b\) ensures that \(\phi(x)\) will be continuous. Clearly, the cos and sin functions fit the requirement, like
\[
\phi_n(x) = \cos\left(\frac{n\pi x}{2b}\right), \quad n = 1, 3, 5, \ldots
\]
and
\[
\phi_n(x) = \sin\left(\frac{n\pi x}{2b}\right), \quad n = 2, 4, 6, \ldots
\]
The eigenvalues then become
\[
E_n = \frac{n^2\pi^2}{4b^2}, \quad n = 1, 2, 3, 4, 5, \ldots
\]
Evidently, two derivatives of either sin or cos just leads to a simple factor times the original term. The norm of the eigenfunctions becomes
\[
\int_{-b}^{b} \left| \cos\left(\frac{n\pi x}{2b}\right) \right|^2 dx < \infty \quad \text{for} \quad n = 1, 3, 5, \ldots
\]
and
\[
\int_{-b}^{b} \left| \sin\left(\frac{n\pi x}{2b}\right) \right|^2 dx < \infty \quad \text{for} \quad n = 2, 4, 6, \ldots
\]
Hence, the Hilbert space is composed of arbitrary sums of these eigenfunctions that lead to finite normalizations.

Clearly, this first section points toward a bona-fide quantization of a particle in a box that has been uniformly accepted; for a standard analysis, see [1].

2 A Common Review of Derivatives

2.1 A toy example of the problem

The feature that is of concern deals with the proper derivatives of the prospective eigenfunctions. This feature can be seen in a simple example.

Consider the continuous function \(f(x)\), where \(-1 < x < 1\), which is defined as \(f(x) = 0\) for \(-1 \leq x \leq 0\), and \(f(x) = x\) for \(0 \leq x \leq 1\).\(^1\) A simple review of derivatives shows that
\[
f'(x) = \lim_{\epsilon \to 0} \frac{f(x + \epsilon) - f(x - \epsilon)}{2\epsilon},
\]
which, for our example, leads to \(f'(x) = 0\) for \(x < 0\) and \(f'(x) = 1\) for \(x > 0\). In addition, we find that \(f'(0) = 1/2\). This result has led to \(f'(x)\) becoming a discontinuous function. The next step is defining
\[
f''(x) = \lim_{\epsilon \to 0} \frac{f'(x + \epsilon) - f'(x - \epsilon)}{2\epsilon}.
\]
The result is that \(f''(x) = 0\) for \(x < 0\) and \(f''(x) = 0\) for \(x > 0\). In addition, it follows that \(f''(0) = \lim_{\epsilon \to 0} [f'(\epsilon) - f'(-\epsilon)]/2\epsilon = \infty\). If we imagine that \(2\epsilon \to dx\), then \(f''(x) = \delta(x)\), which is Dirac’s delta function, formally chosen so that \(\int_{-1}^{1} \delta(x) dx = 1\). Summarizing, we have found that

\(^1\)Picture a flat floor under a flat door that leans upward from the floor at 45 degrees.
\( f''(x) = \delta(x) \). This result has been because \( f'(x) \) is a discontinuous function. Let us add that while \( \int_{-1}^{1} |f''(x)| \ dx < \infty \), it follows that \( \int_{-1}^{1} |f''(x)|^2 \ dx = \infty \), which is the reason to reject \( f''(x) \) in any Hilbert space.

2.2 Application to a particle in a box

The proposed eigenfunction ground state of the particle in a box starts with

\[
\phi_1(x) = \begin{cases} 
0 & \text{for } x \leq -b \\
\cos(\pi x/2b) & \text{for } -b \leq x \leq b \\
= 0 & \text{for } b < x.
\end{cases}
\] (2)

However, two derivatives of the eigenfunction ground state, i.e., \( \phi_1(x) = \cos(\pi x/2b) \), lead to

\[
\phi_1''(x) = \begin{cases} 
0 & \text{for } x < -b \\
(\pi^2/8b^2) \delta(x + b) & \text{for } -b < x < b \\
= 0 & \text{for } b < x.
\end{cases}
\] (3)

This equation does not match the desired form of \(-\hbar^2 \phi''_1(x) = E_1 \phi_1(x)\), and moreover, \( \int_{-\infty}^{\infty} |\phi_1''(x)|^2 \ dx = \infty \), which can not be accepted by any Hilbert space.

While we have only considered the standard ground state, every proposed eigenfunction would have a similar story and \textit{none of them could be a proper eigenfunction with a finite eigenvalue}, e.g., \(-\hbar^2 \phi''_n(x) = E_n \phi_n(x)\) with \(|E_n| < \infty \). Nor would they belong to the usual Hilbert space due to having \( \delta(x \pm b) \) terms in their second derivative. In the author’s opinion, this behavior fails the conventional quantization of a particle in a box, as it was reviewed in Sec. 1.

In the next section, we will propose a valid quantization of the particle in a box using an alternate quantization procedure.

2.3 Half of the expected eigenfunctions

The sentence, taken from Sec. 1, “This connection at \( x \pm b \) ensures that \( \phi(x) \) will be continuous. Clearly, the cos and sin functions fit the requirement, like \( \phi_n(x) = \cos(n\pi x/2b) \), for \( n = 1, 3, 5, \ldots \), and \( \phi_n(x) = \sin(n\pi x/2b) \), for
$n = 2, 4, 6, \ldots$ makes it clear that only half of the sin and cos terms have been accepted. This means that the standard box treatment leads to only half of the set of eigenfunctions that were presumed.

3 A Valid Quantization of the Particle in a Box

Instead of CQ, we use affine quantization (AQ) in order to produce a valid quantization of the particle in a box. Fortunately, AQ has been designed to deal with reduced coordinate spaces.

3.1 A brief review of affine quantization

Some classical problems require reduced coordinates, like the half-harmonic oscillator with the classical Hamiltonian $H = (p^2 + q^2)/2$ provided that $q > 0$. In so doing, $P^\dagger \neq P$, and we seek substitutes for $p$ and $P$. We choose the dilation variable $d = pq$ and $q$ as the new variables. To ensure their independence, we eliminate $q = 0$, and then discard all $q < 0$, keeping all $q > 0$. The basic affine quantum operators are now $D = (P^\dagger Q + QP)/2$ and $Q > 0$. Coherent states, used to connect classical and quantum realms [2], have established that with special classical variables we find that $H'(d, q) \rightarrow H'(D, Q)$. This implies that the classical Hamiltonian can now be $H' = (d^2/q^2 + q^2)/2$, along with $q > 0$, and the affine quantum Hamiltonian for this model then becomes

$$H' = (DQ^{-2}D + Q^2)/2 = [P^2 + (3/4)\hbar^2/Q^2 + Q^2]/2. \quad (4)$$

Happily, the ‘3/4’ term ensures that both $P^\dagger$ and $(P^\dagger)^2$ act like $P$ and $P^2$ in this equation.

This example has proved its validity in several papers that have exposed the eigenfunctions and eigenvalues for the half-harmonic oscillator [3, 4, 5]. This favorable result for the eigenfunctions being of the form $\phi_n(x) = x^{3/2}(\text{polynomial})_n e^{-x^2/2\hbar}$, with $n = 0, 1, 2, \ldots$, a fact that the first derivative remains a completely continuous function. To see what the $x^{3/2}$ factor can do for the relevant two derivatives, just examine the simple equation $[-\hbar^2 (d^2/dx^2) + (3/4)\hbar^2/x^2] x^{3/2} = ?$.

\footnote{A real-life example, is cutting a long thread into two parts and only keeping one of them.}
3.2 Affine quantization of the particle in a box

The example of the last section removed \( q = 0 \) from the coordinate space. Now we remove two points, namely \( q = -b \) and \( q = b \). That leaves three different spaces, and we keep only the middle part, namely, where \(-b < q < b\). We use a suitable dilation variable, namely, \( d' = p(b^2 - q^2) \), along with \( q \), which is restricted by \(-b < q < b\). Next, we offer \( D' = [P^\dagger(b^2 - Q^2) + (b^2 - Q^2)P]/2 \), and \(-b < Q < b\).

Using the new affine variables, the classical Hamiltonian is \( p^2 = d'(b^2 - q^2)^{-2}d' \), which is promoted to

\[
H' = D'(b^2 - Q^2)^{-2}D' = P^2 + \hbar^2[2Q^2 + b^2]/[(b^2 - Q^2)^2].
\]

This \( \hbar \)-factor has been selected from a general study of various dilation operators in [6].

It is noteworthy to examine the last equation when \( Q \) accepts a Schrödinger representation, i.e., \( Q = x \), and \( x \) is extremely close to either \( \pm b \). In that case, \( [2x^2 + b^2]/[(b^2 - x^2)^2] \simeq (3/4)/(b \pm x)^2 \), a relation that closely resembles the very strong properties from the present model with those of the former model. Using this fact leads to the suggestion that part of any eigenfunction of (5) is likely to be \( \psi(x) = (b^2 - x^2)^{3/2} \) (remainder).³

Efforts to find eigenvalues and eigenfunctions for (5) are open to help shed further information on this effort to find a proper quantization of the particle in a box.

4 Conclusion

Affine quantization has also been able to help with other problems as well. Recent efforts have been focused on quantum field theory [7], and the introduction of an affine path integral quantization of gravity [8]. Another article features a direct comparison of CQ and AQ regarding the half-harmonic oscillator with its important implications for gravity and field theory [9].

³A very different use of (5) is to accept the outside space, \( |x| > b \), and reject \( |x| < b \), which then it becomes an ‘anti-box’. Now this system has a similarity to a toy ‘black hole’. It may happen that particles could pile up close to an ‘end of space’, while being attracted by a simple, ‘gravity-like’, pull of a potential such as \( V(x) = W/|x| \). If you choose AQ, the \( \hbar \)-term in (5) could prevent the particles from falling ‘out of space’.
Thanks are given to B.-S. Skagerstam, S. Shabanov, J. Govaerts, and A. Kempf for helpful comments of earlier versions of this paper.
