CLASS NUMBERS VIA 3-ISOGENIES
AND ELLIPTIC SURFACES

CAM MCLEMAN AND DUSTIN MOODY

Abstract. We show that a character sum attached to a family of 3-
isogenies defined on the fibers of a certain elliptic surface over $\mathbb{F}_p$, relates
to the class number of the quadratic imaginary number field $\mathbb{Q}(\sqrt{-p})$.
In this sense, this provides a higher-dimensional analog of some recent
class number formulas associated to 2-isogenies of elliptic curves.

1. Introduction

From the days of Diophantus, elliptic curves have long attracted the
interest of mathematicians. More recently, elliptic curves have found appli-
cations in diverse areas such as the proof of Fermat’s last theorem, factor-
ing large integers, and in cryptography. An area worth particularly men-
tioning is the study of various character sums on the points of an elliptic
curve, which have been used to sum primes, find generators for elliptic curve
groups, and determine the structure of such groups by demonstrating the
uniformity of the distribution of certain points (see, for example, [1], [2], [3],
[4], [5], [8], [9], or [11]). A new direction in this area has been to examine
integer-weighted character sums over elliptic curves [6], [7]. In this vein we
recall two results, whose interplay motivates the main result of this paper.

First, to certain 2-isogenies $\tau$ of elliptic curves defined over $\mathbb{F}_p$, McLeman
and Rasmussen attach an integer-valued character sum $S_\tau$, which is shown
to be divisible by $p$ (see [6]). The subsequent analysis of the quotient $S_\tau/p$
turns out to be of arithmetic significance, providing a new class number
formula strikingly similar to a classical result of Dirichlet’s. Namely, we have
\begin{equation}
-\frac{1}{p} S_\tau = h_p^*,
\end{equation}
where

$$h_p^* = \begin{cases} 
  h(\mathbb{Q}(\sqrt{-p})) & \text{if } p \equiv 3 \pmod{4} \\
  0 & \text{otherwise.}
\end{cases}$$

Here $p$ is a prime and $h(\mathbb{Q}(\sqrt{-p}))$ denotes the class number of $\mathbb{Q}(\sqrt{-p})$.

Key words and phrases. elliptic curve, elliptic surface, class number, character sum.
A second family of results from [7] computes the mod-$p$ value of a much larger class of analogous character sums attached to isogenies of larger degree, and specifically, finds several new classes of character sums which are also evenly divisible by $p$. In light of the above class number formula, it seems of interest to determine the analogous quotients. The current article addresses the analysis of such quotients, focusing on one particular family of 3-isogeny sums satisfying precisely this divisibility condition. We show that when this family of character sums is viewed as a single character sum over an elliptic surface, these quotients also compute class numbers of quadratic imaginary number fields. In this sense, this can be viewed as a higher-dimensional analog of (1.1).

**Statement of Results** — We begin with some notation. Let $p$ and $\ell$ be primes, with $p \equiv 1 \pmod{\ell}$. Let $\tau: E \to E'$ be an $\ell$-isogeny of elliptic curves defined over the finite field $\mathbb{F}_p$. Let $\zeta = \zeta_\ell$ denote a fixed primitive complex $\ell$-th root of unity, and choose a point $Q \in E'(\mathbb{F}_p) - \tau(E(\mathbb{F}_p))$. We will see in Corollary 2 that the particular choice of $Q$ does not matter. From the isomorphism $E'(\mathbb{F}_p)/\tau(E(\mathbb{F}_p)) \cong \mathbb{Z}/\ell\mathbb{Z}$, for each $P \in E'(\mathbb{F}_p)$ we have $P - kQ \in \tau(E(\mathbb{F}_p))$ for a unique $0 \leq k \leq \ell - 1$. We define the character $\chi_\tau$ attached to $\tau$ by:

$$\chi_\tau(P) = \zeta^k, \quad \text{where } P - kQ \in \tau(E(\mathbb{F}_p)).$$

In particular, $\chi_\tau(P) = 1$ if and only if $P$ is in the image of $\tau$.

We adopt the following notation for lifting from $\mathbb{F}_p$ to $\mathbb{Z}$: for $a \in \mathbb{F}_p$, let $\{a\}$ denote the unique integer $0 \leq \{a\} \leq p - 1$ such that $\{a\} \mod p = a$. For the remainder of this paper we will use $E(\mathbb{F}_p)$ to denote the set of affine $\mathbb{F}_p$-rational points on the curve. That is, we do not include the point $\infty$ in $E(\mathbb{F}_p)$. Finally, given a point $P \in E(\mathbb{F}_p)$, let $x(P)$ be the $x$-coordinate of $P$.

Notation in hand, we turn to more precise formulations of the two aforementioned motivating results. The first is the definition of the character sum $S_\tau$ appearing in (1.1). Let $\tau: E \to E'$ be a 2-isogeny defined over $\mathbb{F}_p$, and let $\chi_\tau$ be the character attached to $\tau$ described above. To such a $\tau$, we introduce the integer-valued character sum

$$S_\tau := \sum_{P \in E'(\mathbb{F}_p)} \{x(P)\} \chi_\tau(P).$$

For a concrete example of a situation in which (1.1) holds, one can take (6, Proposition 2) $E$ and $E'$ to both be the curve $y^2 = (x + 2)(x^2 - 2)$ over the finite field $\mathbb{F}_p$ for any prime $p > 3$ of good and ordinary reduction, and
\(\tau\) a degree-2 endomorphism of \(E\) arising from complex multiplication on \(E\) (by \(\mathbb{Z}[\sqrt{-2}]\)). If we let \(p = 131\), for example, then it can be checked that \(S_\tau = -655\), and indeed 655/131 = 5 is the class number of \(\mathbb{Q}(\sqrt{-131})\).

The second motivating result concerns a second class of isogenies \(\tau\) which give character sums divisible by \(p\), but for which we do not know the analogous value of \(S_\tau/p\). To wit, let \(p \equiv 1 \mod 3\), and let \(E_d/\mathbb{F}_p\) be the elliptic curve given by \(y^2 = x^3 + d\). If we set \(d' = -27d \in \mathbb{F}_p\), the function

\[
\tau_d(x, y) := \left(\frac{y^2 + 3d}{x^2}, \frac{y(x^3 - 8d)}{x^3}\right)
\]

defines a 3-isogeny from \(E_d\) to \(E_{d'}\). Let us further suppose that \((\frac{d}{p}) = 1\) to isolate the interesting cases of the character sum\(^1\) Then we have the following divisibility result:

**Theorem 1.** Let \(p\) and \(\tau_d: E_d \to E_{d'}\) be as above, with character \(\chi_{\tau_d}\). Then

\[
S_{\tau_d} := \sum_{P \in E_{d'}(\mathbb{F}_p)} \{x(P)\} \chi_{\tau_d}(P)
\]

is an integer divisible by \(p\).

This theorem can be established using the techniques in \[7\]. We include a proof in this work, as it is a stepping stone to prove our main result. Worth mentioning is the following corollary of Theorem 1\(^1\)

**Corollary 2.** Since \(S_{\tau_d} \in \mathbb{Z}\), we note that \(S_{\tau_d}\) is independent of the choice of the point \(Q \in E_{d'}(\mathbb{F}_p) - \tau_d(E_d(\mathbb{F}_p))\) used to define \(\chi_{\tau_d}\).

Unlike the sum in \((1.1)\), however, there does not seem to be a direct relationship between the individuals sums \(S_{\tau_d}\) and any relevant class number. Instead, we will see that class numbers arise as a sum of quotients \(S_{\tau_d}/p\) as \(d\) runs over the set of all quadratic residues mod \(p\). In fact, the process of summing over all such \(d\) permits a concise reformulation in terms of elliptic surfaces, which we describe now. We begin with the substitution \(d = z^2\), so that running over all \(z \in \mathbb{F}_p^\times\) is equivalent to running over all square \(d\) twice. After the substitution, we arrive at the algebraic surface

\[
\widetilde{E}/\mathbb{F}_p: \quad y^2 = x^3 + z^2.
\]

More specifically, \(\widetilde{E}\) is an elliptic surface, as the projection \(\pi: \mathcal{E} \to \mathbb{A}^1_z\) from \(\mathcal{E}\) on to the affine \(z\)-line equips the surface with a natural elliptic

\(^1\)If \(d\) is a non-square mod \(p\), then \(E_d\) has a \(\mathbb{F}_p\)-rational subgroup of order 3 but no \(\mathbb{F}_p\)-rational 3-torsion point. The isogeny \(\tau\) corresponding to this subgroup is now surjective, and the character \(\chi_\tau\) degenerates to the trivial character.
fibration, with a single singular fiber over $z = 0$. Let $E = \tilde{E} - E_0$ denote
the complement of the singular fiber. The above isogenies $\tau_d = \tau_{z^2}$ can
now be interpreted as maps from one fiber of $E$ to another, namely from
the fiber over $z$ to the fiber over $-27z$. We patch these fiberwise-defined
isogenies together to give a global endomorphism $\tau: E \to E$ which respects
the fibration in the sense that $\pi(P_1) = \pi(P_2)$ implies $\pi(\tau(P_1)) = \pi(\tau(P_2))$
for points $P_1, P_2 \in E(\mathbb{F}_p)$. We simply set
\[
\tau(x, y, z) = \left(\frac{y^2 + 3z^2}{x^2}, \frac{y(x^3 - 8z^2)}{x^3}, -27z\right).
\]

We also extend the character $\chi_{\tau_d}$, defined \textit{a priori} on each fiber to a
global function on $E$: For $P = (x, y, z) \in E$, we have $(x, y) \in E_{z^2}$, and hence
it is sensible to write
\[
\chi_\tau(P) = \chi_{\tau_{z^2}}(x, y).
\]
Note that, as before, $\chi_\tau(P) = 1$ if and only if $P$ is in the image of $\tau$. Finally,
we construct the higher-dimensional character sum. Define
\[
S_\tau = \sum_{P \in E} \{x(P)\} \chi_\tau(P).
\]
The principal result of this work is the following theorem.

\textbf{Main Theorem.} Let $p \equiv 1 \pmod{3}$, and let $E$, $\tau$, $\chi_\tau$, and $S_\tau$
be as above. Then
\[
\frac{1}{p} S_\tau = h^*_p - \frac{p - 1}{2}.
\]

Our technique for calculating the sum $S_\tau$ defined on $E$ is essentially
division of labor between two approaches. We will independently sum
“vertically” (over fibers) and “horizontally” (over sections) over our surface.
Section 2 deals with the former, analyzing the fiber-wise isogenies $\tau_d$
defined in the Introduction, and we address the global calculation of $S_\tau$ in Section
3.

\section{Fiberwise-sums and the Tate pairing}

We maintain the notation established in the introduction. Namely, we
have $p \equiv 1 \pmod{3}$, a value $d \in \mathbb{F}_p^*$ with $\left(\frac{d}{p}\right) = 1$, and the 3-isogeny of
$\mathbb{F}_p$-curves $\tau_d: E_d \to E_d$ with $d' = -27d$. Note that the conditions on $p$ and
$d$ imply
\[
\left(\frac{d}{p}\right) = \left(\frac{-3}{p}\right) = \left(\frac{-3d}{p}\right) = 1.
\]
We begin with an analysis of the contribution to $S_\tau$ coming from a given fiber. Set

$$S_{\tau_d} := \sum_{P \in E_d'(\mathbb{F}_p)} \{x(P)\} \chi_{\tau_d}(P),$$

so that by viewing $S_\tau$ as a sum over fibers, we see

$$S_\tau = 2 \sum_{d=0}^{p-1} S_{\tau_d}.$$

As in [6], the first step in evaluating $S_{\tau_d}$ is to use the Tate pairing to provide explicit formulas for the computation of $\chi_{\tau_d}$. Let us briefly recall the construction of the (complex-valued) Tate pairing attached to $\tau_d$, and its connection to the character $\chi_{\tau_d}$. Let $\hat{\tau_d}$ be the dual isogeny to $\tau_d$ and consider the point $T = (0, 3\sqrt{-3d})$, which generates of the group $E_d'[\hat{\tau_d}](\mathbb{F}_p)$. One begins by finding a pair of functions $f_T$ and $g_T$ such that $\text{div}(f_T) = 3[T] - 3[\infty]$ and $f_T \circ \tau_d = g_T^3$. The Tate pairing

$$\psi_{\tau_d} : \frac{E_d'(\mathbb{F}_p)}{\tau_d(E_d(\mathbb{F}_p))} \times E_d'[\hat{\tau_d}](\mathbb{F}_p) \to \mu_3(\mathbb{C}),$$

is the (bilinear and non-degenerate) pairing given by the cubic residue symbol

$$\psi_{\tau_d}([P], kT) = \left( \frac{\psi'_{\tau_d}([P], kT)}{3} \right),$$

where $[P]$ denotes the image of $P$ in the quotient $E_d'(\mathbb{F}_p)/\tau_d(E_d(\mathbb{F}_p))$, and after choosing an arbitrary point $R \in E_d'(\mathbb{F}_p) - \langle T \rangle$, we set

$$(2.1) \quad \psi'_{\tau_d}([P], kT) := \begin{cases} 
  f(P)^k & [P] \notin \langle [T] \rangle \\
  (f(P+R))^k & [P] \in \langle [T] \rangle.
\end{cases}$$

We use $\mu_3(\mathbb{C})$ to denote the set of cubic roots of unity in $\mathbb{C}$.

**Remark 3.** The definition of the Tate pairing in (2.1) actually outputs a value in $\mathbb{F}_p^*/(\mathbb{F}_p^*)^3$, so we compose this version of the Tate pairing with an isomorphism $\mathbb{F}_p^*/(\mathbb{F}_p^*)^3 \cong \mu_3(\mathbb{C})$. In the proof of Theorem 5, we will choose the isomorphism which forces the Tate pairing to coincide with our character $\chi_{\tau_d}$.

**Proposition 4.** Letting $E_d$, $E_d'$, $\tau_d$, and $T$ as above, we can take

$$f_T = y - 3\sqrt{-3d} \quad \text{and} \quad g_T = \frac{y - \sqrt{-3d}}{x},$$

in the definition of the Tate pairing.
Proof. We easily check that $f_T$ is of degree 3 and vanishes only at $T$, so \( \text{div}(f_T) = 3[T] - 3[\infty] \). Now we need only to verify that as functions on $E_{d'}$, \( f_T \circ \tau_d \) is the cube of $g_T$. For a point \( P = (x, y) \in E_1(\mathbb{F}_p) \) (i.e., satisfying \( x^3 = y^2 - d \)), we have

\[
\begin{align*}
  f \circ \tau(P) &= \frac{y(x^3 - 8d)}{x^3} - 3\sqrt{-3d} \\
  &= \frac{y(y^2 - 9d) - 3\sqrt{-3d}(y^2 - d)}{x^3} \\
  &= \left( \frac{y - \sqrt{-3d}}{x} \right)^3,
\end{align*}
\]

as desired. \( \square \)

**Theorem 5.** With $E_d$, $\tau_d$, and $T$ as above, we have the following explicit formulas for the character $\chi_{\tau_d}$:

\[
(2.2) \quad \chi_{\tau_d}(P) = \psi_{\tau_d}([P], T) = \begin{cases} 
\left( \frac{-4d}{p} \right)^k_3 & \text{if } [P] = [kT], 
\frac{y - \sqrt{-3d}}{x}_3 & \text{otherwise}.
\end{cases}
\]

Note in particular that $\chi_{\tau_d}(P) = 1$ if and only if $P \in \tau_d(E_1(\mathbb{F}_p))$.

Proof. Let us abbreviate $\tau = \tau_d$ for the duration of the proof. For the statement that $\chi_{\tau}(\cdot) = \psi_{\tau}([\cdot], T)$, we first show that a point $P \in E_d(\mathbb{F}_p)$ is in the image of $\tau$ if and only if $\psi_{\tau}([P], T) = 1$. By bilinearity, $\psi_{\tau}([P], kT) = \psi_{\tau}([P], T)^k$. As $E_2[\tau]$ is generated by $T$, $P$ pairs trivially with $T$ if and only if it pairs trivially with every element of $E_2[\tau]$. By the left non-degeneracy of $\psi_{\tau}$, this occurs if and only if $[P]$ is the trivial class of $E_2(\mathbb{F}_p)/\tau(E_1(\mathbb{F}_p))$, i.e., $P$ is in the image of $\tau$. This shows that $\chi_{\tau}(\cdot) = \psi_{\tau}([\cdot], P)$ or $\chi_{\tau}(\cdot) = \psi_{\tau}^{-1}([\cdot], P)$. As in Remark 3 we now choose the correct isomorphism to achieve equality.

We proceed to the second equality in the statement of the theorem. Since the bottom case is the definition of the Tate pairing for such points (given the calculation of $f_T$ from the previous proposition), we only need to address the top case. For this it suffices to show that $\chi_{\tau}(T) = 1$ if and only if $\left( \frac{-4d}{p} \right)_3 = 1$. Let $\alpha$ be a square root of $-3d$ in $\mathbb{F}_p$, such that $T = (0, 3\alpha)$. Suppose first $\left( \frac{-4d}{p} \right)_3 = 1$, so that we have some $\delta \in \mathbb{F}_p$ with $\delta^3 = -4d$. Then

\[
\tau(\delta, \alpha) = \left( \frac{\alpha^2 + 3d}{\delta^2}, \frac{\alpha(\delta^3 - 8d)}{\delta^3} \right) = \left( 0, \frac{-12d\alpha}{-4d} \right) = T,
\]
which shows that $\chi_{\tau}(T) = 1$.

For the converse, we assume there exists $x, y \in \mathbb{F}_p$, with $\tau(x, y) = (0, 3\alpha)$. This requires that $\frac{y^2 + 3d}{x^2} = 0$ and $\frac{y(x^3 - 8d)}{x^3} = 3\alpha$. From the first of these equations we see that $y^2 = -3d$. As the point $(x, y)$ is on the curve $y^2 = x^3 + d$, it follows that $x^3 = -4d$, so $\left(\frac{-4d}{p}\right)_3 = 1$. □

With these explicit formulas for $\chi_{\tau_d}$ in hand, we now prove Theorem 1.

**Theorem 1.** Let $p, E_d, E_{d'}$, and $\tau_d$ be as above. Then

$$S_{\tau_d} := \sum_{P \in E_{d'}(\mathbb{F}_p)} \{x(P)\} \chi_{\tau_d}(P)$$

is an integer divisible by $p$.

**Proof.** Since the values of $\{x(P)\}$ are 0 for $P \in \langle T \rangle$, they contribute trivially to the sum (no matter the value of $\chi_{\tau_d}(P)$). This allows us to avoid breaking the sum into cases based on the results of the Tate pairing. We have

$$\sum_{P \in E_{d'}(\mathbb{F}_p)} \{x(P)\} \chi_{\tau}(P) = \sum_{P \in E_{d'}(\mathbb{F}_p)} \{x(P)\} \left(\frac{y(P) - 3\sqrt{-3d}}{p}\right)_3$$

$$= \sum_{y=0}^{p-1} \sum_{x=0}^{p-1} x \left(\frac{y - 3\sqrt{-3d}}{p}\right)_3$$

$$= \sum_{y=0}^{p-1} \left(\frac{y - 3\sqrt{-3d}}{p}\right)_3 \sum_{x=0}^{p-1} x.$$

Now each inner summand here is the sum of the lifts of the mod-$p$ cube roots of $y^2 + 27d$. This sum is necessarily zero mod $p$ since the coefficient of $x^2$ in the polynomial $x^3 - (y^2 + 27d)$ is trivial. Thus the whole sum is divisible by $p$, as desired. □

### 3. The Global Sum

We recall the global setting from the introduction. The surface $\mathcal{E}$ is the complement of the singular fiber over $z = 0$ in the elliptic surface defined over $\mathbb{F}_p$ by $y^2 = x^3 + z^2$. As such, $\mathcal{E}$ is the union of fibers over non-zero $z \in \mathbb{F}_p$. For $P = (x, y, z) \in \mathcal{E}$, we have $(x, y) \in E_{sz}$, and we glue together the fiber-wise isogenies $\tau_d$ to a global function $\tau$ and global character $\chi_{\tau}$ by defining

$$\chi_{\tau}(P) = \chi_{\tau_{sz}}(x, y).$$
The global sum $S_\tau$ from the main theorem now decomposes as (twice) the sum of the fiberwise-sums addressed in the previous section:

$$S_\tau := \sum_{P \in \mathcal{E}} \{x(P)\} \chi_{\tau}(P) = 2 \sum_{d \in \mathbb{F}_p, \left(\frac{d}{\mathcal{E}}\right) = 1} S_{\tau_d}.$$ 

As an immediate corollary of Theorem 1, we have the divisibility of the global sum.

**Corollary 6.** With notation as previously defined, $p \mid S_\tau$.

We now let $\beta$ denote a fixed square root of $-27 \pmod{p}$, and introduce the characteristic function

$$e(x, y, z) := \begin{cases} 1 & \text{if } y^2 \equiv x^3 - 27z^2 \pmod{p}, \\ 0 & \text{otherwise} \end{cases}$$
on points $(x, y, z) \in \mathbb{F}_p^3$. The explicit computation of the Tate pairing, using the function $f_T = y - 3\sqrt{-3} z = y - \beta z$ in the fiber $E_z$ provides the following formula for $S_\tau$.

$$S_\tau = \sum_{x=1}^{p-1} \sum_{y=0}^{p-1} \sum_{z=1}^{p-1} x \left(\frac{y - \beta z}{p}\right)_3,$$

$$= \sum_{x=1}^{p-1} \sum_{y=0}^{p-1} \sum_{z=1}^{p-1} x \left(\frac{y - \beta z}{p}\right)_3 e(x, y, z). \quad (3.1)$$

We re-arrange the orders of summation and use symmetries of the function $e(x, y, z)$ to simplify the sum. First, we write the sum as

$$\sum_{x=1}^{p-1} \sum_{y=0}^{p-1} \sum_{z=1}^{p-1} x \left(\frac{y - \beta z}{p}\right)_3 e(x, y, z),$$

and for a fixed $x$ and $y$ we address the innermost sum

$$s(x, y) := \sum_{z=1}^{p-1} \left(\frac{y - \beta z}{p}\right)_3 e(x, y, z).$$

Note for a fixed $x$ and $y$, there exists a $z$ (with $1 \leq z \leq p - 1$) such that $e(x, y, z) = 1$ if and only if $y^2 - x^3 - 27z^2$ is a square mod $p$. In this case there are precisely two such $z$’s, which we will denote by $\pm z_0$. We then have

$$s(x, y) = \left(\frac{y - \beta z_0}{p}\right)_3 + \left(\frac{y + \beta z_0}{p}\right)_3,$$

$$= \begin{cases} 1 + 1 = 2 & \text{if } \left(\frac{y - \beta z_0}{p}\right)_3 = 1, \\
\zeta + \zeta^{-1} = -1 & \text{otherwise.} \end{cases}$$
Here we have used that \( \left( \frac{y - \beta z_0}{p} \right)_3 \) and \( \left( \frac{y + \beta z_0}{p} \right)_3 \) are multiplicative inverses by the calculation
\[
\left( \frac{y - \beta z_0}{p} \right)_3 \left( \frac{y + \beta z_0}{p} \right)_3 = \left( \frac{y^2 + 27z_0^2}{p} \right)_3 = \left( \frac{x^3}{p} \right)_3 = 1.
\]

Note that \( z_0 = z_0(x, y) \) can be written (only slightly abusively) as \( \sqrt{\frac{y^2 - x^3}{27}} \), and so we have \( \beta z_0 = \pm \sqrt{y^2 - x^3} \). To summarize, the innermost sum \( s(x, y) \) evaluates as one of three possible cases depending on \( x \) and \( y \):

\[
(3.2) \quad s(x, y) = \begin{cases} 
0 & \text{if } \left( \frac{y^2 - x^3}{p} \right)_3 \neq 1, \\
2 & \text{if } \left( \frac{y^2 - x^3}{p} \right)_3 = 1 \text{ and } \left( \frac{y \pm \sqrt{y^2 - x^3}}{p} \right)_3 = 1, \\
-1 & \text{if } \left( \frac{y^2 - x^3}{p} \right)_3 = 1 \text{ and } \left( \frac{y \pm \sqrt{y^2 - x^3}}{p} \right)_3 \neq 1.
\end{cases}
\]

Recall from equation (3.1)

\[
(3.3) \quad S_p = \sum_{x=1}^{p-1} \sum_{y=0}^{p-1} s(x, y).
\]

Before we evaluate the new inner-most sum, we need a technical result.

**Lemma 7.** Let \( x \neq 0 \) be a fixed element of \( \mathbb{F}_p \). Then

\[
\left| \left\{ y \in \mathbb{F}_p : \left( \frac{y^2 - x^3}{p} \right)_3 = 1 \right\} \right| = \begin{cases} 
(p - 1)/2 & \text{if } \left( \frac{x}{p} \right)_3 = -1, \\
p - 3/2 & \text{if } \left( \frac{x}{p} \right)_3 = 1.
\end{cases}
\]

*Proof.* It is easy to see the number of \( u, v \in \mathbb{F}_p \) with \( uv = x^3 \) is \( p - 1 \): for any non-zero \( u \), let \( v = x^3/u \). For each such solution, let \( y = (u + v)/2 \) and \( c = (u - v)/2 \), which is equivalent to \( u = y + c \) and \( v = y - c \). Thus, the number of solutions to \( (y + c)(y - c) = y^2 - c^2 = x^3 \) is also \( p - 1 \). We may rewrite this equation as \( y^2 - x^3 = c^2 \).

Now suppose first \( x \) is not a square in \( \mathbb{F}_p \). Then \( x^3 \) is not a square, and so there are no values of \( y \) such that \( y^2 - x^3 = 0 \). For each non-zero \( c \), the values \( \pm c \) are distinct and give the same value for \( c^2 \). We see there are \((p - 1)/2\) values of \( y \) for which \( \left( \frac{y^2 - x^3}{p} \right)_3 = 1 \).

If instead \( x \) is a square in \( \mathbb{F}_p \), then so too is \( x^3 \) and there will be two values of \( y \) for which \( y^2 - x^3 = 0 \). This leaves \( p - 3 \) solutions to \( y^2 - x^3 = c^2 \), with \( c \neq 0 \). Again, as \( \pm c \) both lead to the same value of \( c^2 \), we find there are thus \((p - 3)/2\) values of \( y \) for which \( \left( \frac{y^2 - x^3}{p} \right)_3 = 1 \). \( \square \)

With Lemma 7, we can now easily establish the following lemma.
Lemma 8. For a fixed $x \neq 0$,

$$
\sum_{y=0}^{p-1} s(x, y) = -1 - \left( \frac{x}{p} \right).
$$

Proof. Suppose first that $x$ is not a square. We can ignore the values of $y$ for which $\left( \frac{y^2 - x^3}{p} \right) \neq 1$, as then $s(x, y) = 0$ and they do not contribute to the overall sum. So we assume $y^2 - x^3$ is a non-zero square in $\mathbb{F}_p$. We now claim that as we run over these values of $y$, the values $y_1 \pm \sqrt{\frac{y^2 - x^3}{p}}$ are distinct. If this were not the case, then there would exist a $y_1$ and $y_2$ such that

$$
y_1 \pm \sqrt{\frac{y_1^2 - x^3}{p}} = y_2 \pm \sqrt{\frac{y_2^2 - x^3}{p}}.
$$

Squaring both sides of this equation and simplifying, we see

$$
y_1(y_1 \pm \sqrt{\frac{y_1^2 - x^3}{p}}) = y_2(y_2 \pm \sqrt{\frac{y_2^2 - x^3}{p}}).
$$

As $x \neq 0$, then $y_1 \pm \sqrt{\frac{y_1^2 - x^3}{p}} \neq 0$, and similarly for $y_2$. By assumption, $y_1 \pm \sqrt{\frac{y_1^2 - x^3}{p}} = y_2 \pm \sqrt{\frac{y_2^2 - x^3}{p}}$, and as this is non-zero we can divide through by it to see that $y_1 = y_2$.

From Lemma 7, there are $(p-1)/2$ values of $y$ with $\left( \frac{y^2 - x^3}{p} \right) = 1$. Substituting these values into $y \pm \sqrt{\frac{y^2 - x^3}{p}}$ will result in $p - 1$ distinct non-zero values in $\mathbb{F}_p$. It follows that there are $(p-1)/6$ values of $y$ such that $\left( \frac{y \pm \sqrt{\frac{y^2 - x^3}{p}}}{p} \right)_3 = 1$ (or $\zeta$ or $\zeta^2$). So in this case, using (3.2) we see that

$$
\sum_{y=0}^{p-1} s(x, y) = 2 \left( \frac{p-1}{6} \right) - \left( \frac{p-1}{3} \right) = 0
$$

$$
= -1 - \left( \frac{x}{p} \right).
$$

We similarly examine the case when $x$ is a square in $\mathbb{F}_p$. By Lemma 7 again, there are $(p-3)/2$ values of $y$ with $\left( \frac{y^2 - x^3}{p} \right) = 1$. These are the only values for which $s(x, y) \neq 0$. As we run over them, then $y \pm \sqrt{\frac{y^2 - x^3}{p}}$ will run over $p - 3$ distinct non-zero values in $\mathbb{F}_p$. The two values not obtained are when $y = \pm x \sqrt{x}$, as then $y^2 = x^3$ and so $\left( \frac{y^2 - x^3}{p} \right) = 0$. But note that then $y \pm \sqrt{\frac{y^2 - x^3}{p}}$ just equals $y$, and $y = (\pm \sqrt{x})^3$. In short, the values of $\left( \frac{y \pm \sqrt{\frac{y^2 - x^3}{p}}}{p} \right)_3$ will be equidistributed amongst 1, $\zeta$, and $\zeta^2$, except for the
two values in $\mathbb{F}_p^*$, both of which have it equaling 1. So then,

$$
\sum_{y=0}^{p-1} s(x, y) = 2 \left( \frac{p - 1}{6} - 1 \right) - \left( \frac{p - 1}{3} \right)
= -2
= -1 - \left( \frac{x}{p} \right).
$$

This completes the proof. □

Finally, we can complete the proof of the main result.

**Theorem 9.** We have

$$
\frac{S_r}{p} = h_p^* - \frac{p-1}{2}.
$$

**Proof.** By equation (3.3) and Lemma 8 we see that

$$
S_r = \sum_{x=1}^{p-1} x \left( -1 - \left( \frac{x}{p} \right) \right),
= - \sum_{x=1}^{p-1} x \left( \frac{x}{p} \right) - \sum_{x=1}^{p-1} x,
= ph_p^* - \frac{p(p-1)}{2}.
$$

We have used Dirichlet’s result that

$$
\sum_{x=1}^{p-1} x \left( \frac{x}{p} \right) = -ph_p^*.
$$

This completes the proof. □

4. Conclusion

It would be interesting to know whether other families of elliptic curves or surfaces can be found which yield class number formulas similar to the results in this paper. All families of 3-isogenies that we investigated which provided class number formulas ended up being isomorphic to the curves $y^2 = x^3 + d$. It would also be interesting to find analogous formulas for curves with isogenies of degree greater than 3. As mentioned in the Introduction, some divisibility properties have been shown in [7], however not much is known about the corresponding quotients. Finally, we leave it as future work to analyze related character sums, where we weight by other integer valued funtions other than $x(P)$. Preliminary work using $y(P)$ has been shown to have relations with class numbers.
Acknowledgements. The authors would like to thank Christopher Rasmussen for some helpful suggestions, and acknowledge the contribution of SAGE [10], which facilitated the construction of examples which were helpful in discovering the main theorems of this work.
