ABSTRACT. The Regular Post Embedding Problem extended with partial (co)directness is shown decidable. This extends to universal and/or counting versions. It is also shown that combining directness and codirectness in Post Embedding problems leads to undecidability.

1 Introduction

The Regular Post Embedding Problem (PEP for short, named by analogy with Post’s Correspondence Problem) is the problem of deciding, given two morphisms on words \( u, v : \Sigma^* \to \Gamma^* \) and a regular language \( R \in \text{Reg}(\Sigma) \), whether there is \( \sigma \in R \) such that \( u(\sigma) \) is a (scattered) subword of \( v(\sigma) \).

The subword ordering, also called embedding, is denoted “\( \sqsubseteq \)”: \( u(\sigma) \sqsubseteq v(\sigma) \) if \( u(\sigma) \) can be obtained by erasing some letters from \( v(\sigma) \), possibly all of them, possibly none. Equivalently, PEP is the question whether a rational relation, or a transduction, \( T \subseteq \Gamma^* \times \Gamma^* \) intersects non-vacuously the subword relation, hence is a special case of the intersection problem for two rational relations.

This problem is new and quite remarkable: it is decidable [2] but surprisingly hard since it is not primitive-recursive and not even multiply-recursive. In fact, it is at level \( F_{\omega\omega} \) (and not below) in the Fast-Growing Hierarchy [8, 12].

A variant problem, \( \text{PEP}_{\text{dir}} \), asks for the existence of direct solutions, i.e., solutions \( \sigma \in R \) such that \( u(\tau) \sqsubseteq v(\tau) \) for every prefix \( \tau \) of \( \sigma \). The two problems are inter-reducible [4], hence have the same complexity: decidability of PEP entails decidability of \( \text{PEP}_{\text{dir}} \), while hardness of \( \text{PEP}_{\text{dir}} \) entails hardness for PEP.

Our contribution. We introduce \( \text{PEP}_{\text{partial dir}} \), or “PEP with partial directness”, a new problem that generalizes both PEP and \( \text{PEP}_{\text{dir}} \), and prove its decidability. The proof combines two ideas. Firstly, by Higman’s Lemma, a long solution must eventually contain “comparable” so-called cutting points, from which one deduces that the solution is not minimal (or unique, or ...). Secondly, the above notion of “eventually”, that comes from Higman’s Lemma, can be turned into an effective upper bound thanks to a Length Function Theorem. The cutting technique described above was first used in [7] for reducing \( \exists^*\text{PEP} \) to PEP. In this paper we use it to obtain a decidability proof for \( \text{PEP}_{\text{partial dir}} \) that is not only more general but also more direct than the earlier proofs for PEP or \( \text{PEP}_{\text{dir}} \). It also immediately provides an \( F_{\omega\omega} \) complexity upper bound. We also show the decidability of universal and/or counting versions of the extended \( \text{PEP}_{\text{partial dir}} \) problem, and explain how our attempts at further generalisation, most notably by considering the combination of directness and codirectness in a same instance, lead to undecidability.

Applications to channel machines. Beyond the tantalizing decidability questions, our interest in PEP and its variants comes from their close connection with fifo channel machines [11], a family of computational models that are a central tool in several areas of program and system verification (see [5] and the references therein). Here, PEP and its variants provide abstract versions of verification problems for channel machines [4], bringing greater clarity and versatility in both decidability and undecidability (more generally, hardness) proofs.

Beyond providing a uniform and simpler proof for the decidability of PEP and PEPdir, our motivation for considering PEPpartial is that it allows solving the decidability of UCST, i.e., unidirectional channel systems (with one reliable and one lossy channel) extended with the possibility of testing the contents of channels [10]. We recall that PEP was introduced for UCS, unidirectional channel systems where tests on channels are not supported [4][3], and that PEPdir corresponds to LCS, i.e., lossy channel systems, for which verification is decidable using techniques from WSTS theory [1][2][5]. The following figure illustrates the resulting situation.

Outline of the paper. Section 2 recalls basicnotations and definitions. In particular, it explains the Length Function Theorem for Higman’s Lemma, and lists basic results where the subword relation interacts with concatenations and factorization. Section 3 contains our main result, a direct decidability proof for PEPpartial, a problem subsuming both PEP and PEPdir. Section 4 builds on this result and shows the decidability of counting problems on PEPpartial. Section 5 further shows the decidability of universal variants of these questions. Section 6 contains our undecidability results for extensions of PEPpartial. A technical appendix provides all the roofs not given in the main text.

2 Basic notation and definitions

Words. Concatenation of words is denoted multiplicatively, with ε denoting the empty word. If s is a prefix of a word t, s−1t denotes the unique word s′ such that t = ss′, and s−1t is not defined if s is not a prefix of t. Similarly, when s is a suffix of t, ts−1 is t with the s suffix removed. For a word x = a0...an−1, ˜x def = an−1...a0 is the mirrored word. The mirror of a language R is ˜R def = { ˜x | x ∈ R}. We write s ⊑ t when s is a subword (subsequence) of t.

Lemma 1. (Subwords and concatenation, see App.[B]) For all words y, z, s, t:
1. If yz ⊑ st then y ⊑ s or z ⊑ t.
2. If yz ⊑ st and z ⊑ t and x is the longest suffix of y such that xz ⊑ t, then yx−1 ⊑ s.
3. If yz ⊑ st and z ̸⊑ t and x is the shortest prefix of z such that x−1z ⊑ t, then yx ⊑ s.
4. If yz ⊑ st and z ⊑ t and x is the longest prefix of t such that z ⊑ x−1t, then y ⊑ sx.
5. If yz ⊑ st and z ⊑ t and x is the shortest suffix of s such that z ⊑ xt, then y ⊑ sx−1.
6. If xs ⊑ yt and t ⊑ s, then sxk ⊑ ykt for all k ≥ 1.
7. If xs ⊑ ty and t ⊑ s, then xks ⊑ tyk for all k ≥ 1.
With a language $R$ one associates a congruence (wrt concatenation) given by $s \sim_R t \iff \forall x, y (x s y \in R \iff x t y \in R)$ and called the syntactic congruence (also, the syntactic monoid). This congruence has finite index if (and only if) $R$ is regular. For regular $R$, let $n_R$ denote this index: $n_R \leq m^m$ when $R$ is recognized by a $m$-state complete DFA.

Higman’s Lemma. It is well-known that for words over a finite alphabet, $\subseteq$ is a well-quasi-ordering, that is, any infinite sequence of words $x_1, x_2, \ldots$ contains an infinite increasing subsequence $x_i \subseteq x_j \subseteq x_k \subseteq \cdots$. This result is called Higman’s Lemma.

For $n \in \mathbb{N}$, we say that a sequence (finite or infinite) of words is $n$-good if it has an increasing subsequence of length $n$. It is $n$-bad otherwise. Higman’s Lemma tells us that every infinite sequence is $n$-good for every $n$. Hence every $n$-bad sequence is finite.

It is often said that Higman’s Lemma is “non-effective” since it does not give any explicit information on the maximal length of bad sequences. Consequently, when one uses Higman’s Lemma to prove that an algorithm terminates, no meaningful upper-bound on the algorithm’s running time is derived from the proof. However, complexity upper-bound can be derived if the complexity of the sequences (or more precisely of the process that generates bad sequences) is taken into account. The interested reader can consult [12] for more details. Here we only need the simplest version of these results, i.e., the statement that the maximal length of bad sequences is computable.

A sequence of words $x_1, \ldots, x_l$ is $k$-controlled ($k \in \mathbb{N}$) if $|x_i| \leq ik$ for all $i = 1, \ldots, l$.

**Length Function Theorem (see App. A).** There exists a computable function $H : \mathbb{N}^3 \rightarrow \mathbb{N}$ such that any $n$-bad $k$-controlled sequences of words in $\Gamma^*$ has length at most $H(n, k, |\Gamma|)$. Furthermore, $H$ is monotonic in all three arguments.

Thus, a sequence with more than $H(n, k, |\Gamma|)$ words is $n$-good or is not $k$-controlled. We refer to [12] for the complexity of $H$. Here it is enough to know that $H$ is computable.

### 3 Deciding $\text{PEP}_{\text{partial dir}}$, or $\text{PEP}$ with partial directness

We introduce $\text{PEP}_{\text{partial dir}}$, a problem generalizing both PEP and $\text{PEP}_{\text{dir}}$, and show its decidability. This is proved by showing that if a $\text{PEP}_{\text{partial dir}}$ instance has a solution, then it has a solution whose length is bounded by a computable function of the input. This proof is simpler and more direct than the proof (for PEP only) based on blockers [2].

**Definition 2.** $\text{PEP}_{\text{partial dir}}$ is the problem of deciding, given morphisms $u, v : \Sigma^* \rightarrow \Gamma^*$ and regular languages $R, R' \in \text{Reg}(\Sigma)$, whether there is $\sigma \in R$ such that $u(\sigma) \subseteq v(\sigma)$ and $u(\tau) \subseteq v(\tau)$ for all prefixes $\tau$ of $\sigma$ belonging to $R'$ (in which case $\sigma$ is called a solution).

$\text{PEP}_{\text{partial codir}}$ is the variant problem of deciding whether there is $\sigma \in R$ such that $u(\sigma) \subseteq v(\sigma)$ and $u(\tau) \subseteq v(\tau)$ for all suffixes $\tau$ of $\sigma$ that belong to $R'$.

Both PEP and $\text{PEP}_{\text{dir}}$ are special cases of $\text{PEP}_{\text{partial dir}}$, obtained by taking $R' = \emptyset$ and $R' = \Sigma^*$ respectively. Obviously $\text{PEP}_{\text{partial dir}}$ and $\text{PEP}_{\text{partial codir}}$ are two equivalent presentations, modulo mirroring, of a same problem. Given a $\text{PEP}_{\text{partial dir}}$ instance, we let $K_u \overset{\text{def}}{=} \max_{a \in \Sigma} |u(a)|$ denote the expansion factor of $u$ and say that $\sigma \in \Sigma^*$ is long if $|\sigma| > 2H(n_{BG} + 1, K_u, |\Gamma|)$, otherwise it is short (recall that $H(n, k, |\Gamma|)$ was defined with the Length Function Theorem). In this section we prove:
Theorem 3. A PEP\textsubscript{partial} or PEP\textsubscript{partial codir} instance has a solution if, and only if, it has a short solution. This entails that PEP\textsubscript{partial dir} and PEP\textsubscript{partial codir} are decidable.

Decidability is an obvious consequence since the maximal length for short solutions is computable, and since it is easy to check whether a candidate \(\sigma\) is a solution. Furthermore, one derives an upper bound on the complexity of PEP\textsubscript{partial} since the Length Function \(H\) is bounded in \(f_{\mathcal{A}}\) [12].

For the proof of Theorem 3, we find it easier to reason on the codirect version. Pick an arbitrary PEP\textsubscript{partial codir} instance \((\Sigma, \Gamma, u, v, R, R')\) and a solution \(\sigma\). Write \(N = |\sigma|\) for its length, \(\sigma[0, i)\) and \(\sigma[i, N)\) for, respectively, its prefix of length \(i\) and its suffix of length \(N - i\). Two indices \(i, j \in [0, N]\) are congruent if \(\sigma[i, N) \sim_R \sigma(j, N)\) and \(\sigma[i, N) \sim_R \sigma(j, N)\) when \(\sigma\) is fixed, as in the rest of this section, we use shorthand notations like \(u_{0,i}\) and \(v_{i,j}\) to denote the images, here \(u(\sigma[0, i))\) and \(v(\sigma[i, j))\), of factors of \(\sigma\).

We prove two “cutting lemmas” giving sufficient conditions for “cutting” a solution \(\sigma = \sigma[0, N)\) along certain indices \(a < b\), yielding a shorter solution \(\sigma' = \sigma[0, a)\sigma[b, N)\). Here the following notation is useful. We associate, with every suffix \(\tau\) of \(\sigma'\), a corresponding suffix, denoted \(S(\tau)\), of \(\sigma\): if \(\tau\) is a suffix of \(\sigma[b, N)\), then \(S(\tau) = \tau\), otherwise, \(\tau = \sigma[i, a)\sigma[b, N)\) for some \(i < a\) and we let \(S(\tau) = \sigma[i, N)\). In particular \(S(\sigma') = \sigma\).

An index \(i \in [0, N]\) is said to be blue if \(u_{i, N} \subseteq v_{i, N}\), it is red otherwise. In particular, \(N\) is blue trivially, 0 is blue since \(\sigma\) is a solution, and \(i\) is blue whenever \(\sigma[i, N) \in R'\). If \(i\) is a blue index, let \(l_i \in \Gamma^*\) be the longest suffix of \(u_{0,i}\) such that \(l_i u_{i, N} \subseteq v_{i, N}\) and call it the left margin at \(i\).

Lemma 4. (Cutting lemma for blue indices) Let \(a < b\) be two congruent and blue indices. If \(l_a \subseteq l_b\), then \(\sigma' = \sigma[0, a)\sigma[b, N)\) is a solution (shorter than \(\sigma\)).

Proof. Clearly \(\sigma' \in R\) since \(\sigma \in R\) and \(a\) and \(b\) are congruent. Also, for all suffixes \(\tau\) of \(\sigma'\), \(S(\tau) \in R'\) iff \(\tau \in R'\).

We claim that, for any suffix \(\tau\) of \(\sigma'\), if \(u(S(\tau)) \subseteq v(S(\tau))\) then \(u(\tau) \subseteq v(\tau)\). This is obvious when \(\tau = S(\tau)\), so we assume \(\tau \neq S(\tau)\), i.e., \(\tau = \sigma[i, a)\sigma[b, N)\) and \(S(\tau) = \sigma[i, N)\) for some \(i < a\). Assume \(u(S(\tau)) \subseteq v(S(\tau))\), i.e., \(u_{i, N} \subseteq v_{i, N}\). Now at least one of \(u_{i, a}\) and \(l_a\) is a suffix of the other, which gives two cases. If \(u_{i, a}\) is a suffix of \(l_a\), then

\[
u(\tau) = u_{i, a} u_{b, N} \subseteq l_a u_{b, N} \subseteq l_b u_{b, N} \subseteq v_{b, N} \subseteq v(\tau)\,.
\]

Otherwise, \(u_{i, a} = x l_a\) for some \(x\) (see Fig. 1). Then \(u_{i, N} \subseteq v_{i, N}\) rewrites as \(u_{i, a} u_{a, N} = x l_a u_{a, N} \subseteq v_{i, a} v_{a, N}\).

![Figure 1: Schematics for Lemma 4 with \(l_a \subseteq l_b\)](image)

Now, and since \(l_a\) is the longest suffix for which \(l_a u_{a, N} \subseteq v_{a, N}\), Lemma 12 entails \(x \subseteq v_{i, a}\). Combining
with $l_a \sqsubseteq l_b$ (assumption of the Lemma) gives:

$$u(\tau) = u_{i,a}u_{b,N} = xl_a u_{b,N} \sqsubseteq v_{i,a} u_{b,N} \sqsubseteq v_{i,a} v_{b,N} = v(\tau).$$

This shows that $\sigma'$ is a solution (which completes the proof) since we can infer $u(\tau) \sqsubseteq v(\tau)$ for any suffix $\tau \in R'$ (or for $\tau = \sigma'$) from the corresponding $u(S(\tau)) \sqsubseteq v(S(\tau))$.

If $i$ is a red index, let $r_i \in \Gamma^*$ be the shortest prefix of $u_{i,N}$ such that $r_i^{-1}u_{i,N} \sqsubseteq v_{i,N}$ (equivalently $u_{i,N} \sqsubseteq r_i v_{i,N}$) and call it the right margin at $i$.

**Lemma 5. (Cutting lemma for red indices)** Let $a < b$ be two congruent and red indices. If $r_b \sqsubseteq r_a$, then $\sigma' = \sigma[0,a)\sigma(b,N)$ is a solution (shorter than $\sigma$).

**Proof.** Write $u_{b,N}$ under the form $r_{b,x}$ so that $x \sqsubseteq v_{b,N}$. We proceed as for Lemma 4 and show that $u(S(\tau)) \sqsubseteq v(S(\tau))$ implies $u(\tau) \sqsubseteq v(\tau)$ for all suffixes $\tau$ of $\sigma'$. Assume $u(S(\tau)) \sqsubseteq v(S(\tau))$ for some $\tau$. The only interesting case is when $\tau \neq S(\tau)$ and $\tau = \sigma[i,a)\sigma(b,N)$ for some $i < a$ (see Fig. 2).

![Figure 2: Schematics for Lemma 5 with $r_b \sqsubseteq r_a$](image)

From $u_{l,N} = u_{i,a}u_{a,N} \sqsubseteq v_{i,a}v_{a,N} = v_{i,N}$, i.e., $u(S(\tau)) \sqsubseteq v(S(\tau))$, and $u_{a,N} \not\sqsubseteq v_{a,N}$ (since $a$ is a red index), the definition of $r_a$ entails $u_{i,a}r_a \sqsubseteq v_{i,a}$ (Lemma 4). Then

$$u(\tau) = u_{i,a}u_{b,N} = u_{i,a}r_a x \sqsubseteq u_{i,a} r_a v_{b,N} \sqsubseteq v_{i,a} v_{b,N} = v(\tau).$$

We now conclude the proof of Theorem 3. Let $g_1 < g_2 < \cdots < g_{N_1}$ be the blue indices in $\sigma$, let $b_1 < b_2 < \cdots < b_{N_2}$ be the red indices, and look at the corresponding sequences $(l_{g_i})_{i=1,\ldots,N_1}$ of left margins and $(r_{b_i})_{i=1,\ldots,N_2}$ of right margins.

**Lemma 6. (See App. B.2)** $|l_{g_i}| \leq (i - 1) \times K_a$ for all $i = 1,\ldots,N_1$, and $|r_{b_i}| \leq (N_2 - i + 1) \times K_a$ for all $i = 1,\ldots,N_2$. In other words, the sequence on left margins and the reversed sequence of right margins are $K_a$-controlled.

Now, let $N_c \overset{\text{def}}{=} n_{\text{rg}_{K_e}} + 1$ and $L \overset{\text{def}}{=} H(N_c, K_a, |\Gamma|)$ and assume $N > 2L$. Since $N_1 + N_2 = N + 1$, either $\sigma$ has at least $L + 1$ blue indices and, by definition of $L$ and $H$, there exist $N_c$ blue indices $a_1 < a_2 < \cdots < a_{N_c}$ with $l_{a_1} \sqsubseteq l_{a_2} \sqsubseteq \cdots \sqsubseteq l_{a_{N_c}}$, or $\sigma$ has at least $L + 1$ red indices and there exist $N_c$ red indices $d_1 < d_2 < \cdots < d_{N_c}$ with $r_{d_1} \sqsubseteq \cdots \sqsubseteq r_{d_{N_c}} \sqsubseteq r_{d_i}$ (since it is the reversed sequence of right margins that is controlled). Out of $N_c = 1 + n_{\text{rg}_{K_e}}$ indices, two must be congruent, fulfilling the assumptions of Lemma 4 or Lemma 5. Therefore $\sigma$ is not the shortest solution, proving Theorem 3.
4 Counting the number of solutions

We consider two counting questions: \(\exists^\infty\text{PEP}_{\text{dir}}\) is the question whether a \(\text{PEP}_{\text{dir}}\) instance has infinitely many solutions (a decision problem), while \(#\text{PEP}_{\text{dir}}\) is the problem of computing the number of solutions of the instance (a number in \(\mathbb{N} \cup \{\infty\}\)). For technical convenience, we often deal with the (equivalent) codirected versions, \(\exists^\infty\text{PEP}_{\text{codir}}\) and \(#\text{PEP}_{\text{codir}}\).

For an instance \((\Sigma, \Gamma, u, v, R, R')\), we let \(K_v \overset{\text{def}}{=} \max_{a \in \Sigma} |v(a)|\) and define

\[
L \overset{\text{def}}{=} H(n_R n_R' + 1, K_v, |\Gamma|), \quad L' \overset{\text{def}}{=} H\left(n_R (2L + 1) n_R' + 1, K_v, |\Gamma|\right).
\]

We say that a solution \(\sigma \in \Sigma^*\) is long if \(|\sigma| > 2L\) and very long if \(|\sigma| > 2L'\) (note that “long” is slightly different from “not short” from Section 3). In this section we prove:

**Theorem 7.** For a \(\text{PEP}_{\text{dir}}\) or \(\text{PEP}_{\text{codir}}\) instance, the following are equivalent:

(a). It has infinitely many solutions.
(b). It has a long solution.
(c). It has a solution that is long but not very long.

From this, it will be easy to count the number of solutions:

**Corollary 8.** \(\exists^\infty\text{PEP}_{\text{dir}}\) and \(\exists^\infty\text{PEP}_{\text{codir}}\) are decidable, \(#\text{PEP}_{\text{dir}}\) and \(#\text{PEP}_{\text{codir}}\) are computable.

**Proof.** Decidability for the decision problems is clear since \(L\) and \(L'\) are computable.

For actually counting the solutions, we check whether the number of solutions is finite or not using the decision problems. If infinite, we are done. If finite, we first compute an upper bound on the length of the longest solution. For this we build \(\text{PEP}_{\text{dir}}\) (resp. \(\text{PEP}_{\text{codir}}\)) instances where \(R\) is replaced by \(R \cap \Sigma^M\) (which is regular when \(R\) is) for increasing values of \(M \in \mathbb{N}\). When eventually \(M\) is large enough, the instance is negative and this can be detected (by Theorem 4). Once we know that there are no solutions longer than \(M\), counting solutions is done by finite enumeration.

We now prove Theorem 4. First observe that if the instance has a long solution, it has a solution with \(R\) replaced by \(R \cap \Sigma^{>2L}\). This language has a DFA with \(n_R (2L + 1)\) states, thus the associated congruence has index at most \((n_R (2L + 1)) n_R (2L + 1)\). From Theorem 4 the instance has a solution which is long but not very long. Hence (b) and (c) are equivalent.

It remains to show (b) implies (a) since obviously (a) implies (b). For this we fix an arbitrary \(\text{PEP}_{\text{codir}}\) instance \((\Sigma, \Gamma, u, v, R, R')\) and consider a solution \(\sigma\), of length \(N\). We develop two so-called “iteration lemmas” that are similar to the cutting lemmas from Section 3 with the difference that they expand \(\sigma\) instead of reducing it.

As before, an index \(i \in [0,N]\) is said to be blue if \(u_i \subseteq v_{i,N}\), and red otherwise. With blue and red indices we associate words analogous to the \(l_i\)'s and \(r_i\)'s from Section 3 however now they are factors of \(v(\sigma)\), not \(u(\sigma)\) (hence the different definition for \(L\)). The terms “left margin” and “right margin” will be reused here for these factors.

We start with blue indices. For a blue index \(i \in [0,N]\), let \(s_i\) be the longest prefix of \(v_{i,N}\) such that \(u_i \subseteq s_i^{-1} v_{i,N}\) (equivalently \(s_i u_i \subseteq v_{i,N}\)) and call it the right margin at \(i\).
LEMMA 9. Suppose $a < b$ are two blue indices with $s_b \sqsubseteq s_a$. Then for all $k \geq 1$, $s_a(u_{a,b})^k \sqsubseteq (v_{a,b})^k s_b$.

PROOF. $s_a u_{a,N} \sqsubseteq v_{a,N}$ expands as $(s_a u_{a,b}) u_{b,N} \sqsubseteq v_{a,b} v_{b,N}$. Since $u_{b,N} \sqsubseteq v_{b,N}$, Lemma [1]4 yields $s_a u_{a,b} \sqsubseteq v_{a,b} s_b$. One concludes with Lemma[1]6, using $s_b \sqsubseteq s_a$.

LEMMA 10. (Iteration lemma for blue indices, see App.[C.1]) Let $a < b$ be two congruent and blue indices. If $s_b \sqsubseteq s_a$, then for every $k \geq 1$, $\sigma' = \sigma[0,a).\sigma\sigma(a,b)^k.\sigma(b,N)$ is a solution.

Now to red indices. For a red index $i \in [0,N]$, let $t_i$ be the shortest suffix of $v_{0,i}$ such that $u_{i,N} \sqsubseteq t_i v_{i,N}$. This is called the left margin at $i$. Thus, for a blue $j$ such that $j < i$, $u_{j,N} \sqsubseteq v_{j,N}$ implies $u_{j,N} \sqsubseteq t_j v_{j,N}$ by Lemma[1]5.

LEMMA 11. (Iteration lemma for red indices, see App.[C.2]) Let $a < b$ be two congruent and red indices. If $t_a \sqsubseteq t_b$, then for every $k \geq 1$, $\sigma' = \sigma[0,a).\sigma\sigma(a,b)^k.\sigma(b,N)$ is a solution.

We now conclude the proof of Theorem[7] We first prove that the $\text{PEP}^\partial_{\text{dir}}$ instance has infinitely many solutions iff it has a long solution. Obviously, only the right-to-left implication has to be proven.

Suppose there are $N_1$ blue indices in $\sigma$, say $g_1 < g_2 < \cdots < g_{N_1}$; and $N_2$ red indices, say $b_1 < b_2 < \cdots < b_{N_2}$.

LEMMA 12. (See App.[C.3]) $|s_g| \leq (N_1 - i + 1) \times K_v$ for all $i = 1, \ldots, N_1$, and $|t_b| \leq (i - 1) \times K_v$ for all $i = 1, \ldots, N_2$. That is, the reversed sequence of right margins and the sequence of left margins are $K_v$-controlled.

Assume that $\sigma$ is a long solution of length $N \geq 2L + 1$. At least $L + 1$ indices among $[0,N]$ are blue, or at least $L + 1$ are red. We apply one of the two above claims, and from either $s_{g_1}, \ldots, s_{g_1}$ (if $N_1 \geq L + 1$) or $t_{b_1}, \ldots, t_{b_1}$ (if $N_2 \geq L + 1$) we get an increasing subsequence of length $n_R n_R + 1$. Among these there must be two congruent indices. Then we get infinitely many solutions by Lemma[10] or Lemma[11].

5 Universal variants of $\text{PEP}^\partial_{\text{dir}}$

We consider universal variants of $\text{PEP}^\partial_{\text{dir}}$ (or rather $\text{PEP}^\partial_{\text{dir}}$ for the sake of uniformity). Formally, given instances $(\Sigma, \Gamma, u, v, R, R')$ as usual, $\forall \text{PEP}^\partial_{\text{dir}}$ is the question whether every $\sigma \in R$ is a solution, i.e., satisfies both $u(\sigma) \subseteq v(\sigma)$ and $u(\tau) \subseteq v(\tau)$ for all suffixes $\tau$ that belong to $R'$. Similarly, $\forall \text{PEP}^\partial_{\text{dir}}$ is the question whether “almost all”, i.e., $\text{all but finitely many}$, $\sigma$ in $R$ are solutions, and $\# \text{PEP}^\partial_{\text{dir}}$ is the associated counting problem that asks how many $\sigma \in R$ are not solutions.

The special cases $\forall \text{PEP}$ and $\forall \text{PEP}$ (where $R' = \emptyset$) have been shown decidable in [7] where it appears that, at least for Post Embedding, universal questions are simpler than existential ones. We now observe that $\forall \text{PEP}^\partial_{\text{dir}}$ and $\forall \text{PEP}^\partial_{\text{dir}}$ are easy to solve too: partial codirectness constraints can be eliminated since universal quantifications commute with conjunctions (and since the codirectness constraint is universal itself).

LEMMA 13. $\forall \text{PEP}^\partial_{\text{dir}}$ and $\forall \text{PEP}^\partial_{\text{dir}}$ many-one reduce to $\forall \text{PEP}$. 
COROLLARY 14. \( \forall \text{PEP}_{\text{partial codir}}^{\text{partial}} \) and \( \forall \text{PEP}_{\text{partial codir}}^{\text{partial}} \) are decidable, \( \# \text{PEP}_{\text{partial codir}}^{\text{partial}} \) is computable.

We now prove Lemma\[13\]. First, \( \forall \text{PEP}_{\text{partial codir}}^{\text{partial}} \) easily reduces to \( \forall \text{PEP}_{\text{partial codir}}^{\text{partial}} \) : add an extra letter \( z \) to \( \Sigma \) with \( u(z) = v(z) = \varepsilon \) and replace \( R \) and \( R' \) with \( R.z' \) and \( R'.z' \). Hence the second half of the lemma entails its first half by transitivity of reductions.

For reducing \( \forall \text{PEP}_{\text{partial codir}}^{\text{partial}} \), it is easier to start with the negation of our question:

\[
\exists^\omega \sigma \in R : (u(\sigma) \nsubseteq v(\sigma)) \text{ or } \sigma \text{ has a suffix } \tau \text{ in } R' \text{ with } u(\tau) \nsubseteq v(\tau)) . \tag{**}
\]

Call \( \sigma \in R \) a type 1 witness if \( u(\sigma) \nsubseteq v(\sigma) \), and a type 2 witness if it has a suffix \( \tau \in R' \) with \( u(\tau) \nsubseteq v(\tau) \). Statement \( \Box \) holds if, and only if, there are infinitely many type 1 witnesses or infinitely many type 2 witnesses. The existence of infinitely many type 1 witnesses (call that “case 1”) is the negation of a \( \forall \text{PEP} \) question. Now suppose that there are infinitely many type 2 witnesses, say \( \sigma_1, \sigma_2, \ldots \) . For each \( i \), pick a suffix \( \tau_i \) of \( \sigma_i \) such that \( \tau_i \in R' \) and \( u(\tau_i) \nsubseteq v(\tau_i) \). The set \( \{ \tau_i \mid i = 1, 2, \ldots \} \) of these suffixes can be finite or infinite. If it is infinite (“case 2a”), then

\[
u(\tau) \nsubseteq v(\tau) \text{ for infinitely many } \tau \in (\overrightarrow{R} \cap R') \]  

where \( \overrightarrow{R} \) is short for \( \exists^\omega R \) and for \( k \in \mathbb{N} \), \( \exists^k R \) def \( \{ y \mid \exists x : (|x| \geq k \text{ and } xy \in R) \} \) is the set of the suffixes of words from \( R \) one obtains by removing at least \( k \) letters. Observe that, conversely, \( \exists^\omega R \) implies the existence of infinitely many type 2 witnesses (for a proof, pick \( \tau_1 \in \overrightarrow{R} \cap R' \) satisfying the above, choose \( \sigma_1 \in R \) of which \( \tau_1 \) is a suffix. Then choose \( \tau_2 \) such that \( |\tau_2| > |\sigma_1| \), and proceed similarly).

On the other hand, if \( \{ \tau_i \mid i = 1, 2, \ldots \} \) is finite (“case 2b”), then there is a \( \tau \in R' \) such that \( u(\tau) \nsubseteq v(\tau) \) and \( \sigma' \tau \in R \) for infinitely many \( \sigma' \). By a standard pumping argument, the second point is equivalent to the existence of some such \( \sigma' \) with also \( |\sigma'| > kR \), where \( kR \) is the size of a NFA for \( R \) (taking \( kR = nR \) also works). Write now \( \hat{R} \) for \( \exists^k R \) if \( \{ \tau_i \mid i = 1, 2, \ldots \} \) is finite, then \( u(\tau) \nsubseteq v(\tau) \) for some \( \tau \) in \( (\hat{R} \cap \hat{R'}) \), and conversely this implies the existence of infinitely many type 2 witnesses.

To summarize, and since \( \overrightarrow{R} \) and \( \hat{R} \) are regular and effectively computable from \( R \), we have just reduced \( \forall \text{PEP}_{\text{partial codir}}^{\text{partial}} \) to the following conjunction

\[
\forall^\omega \sigma \in R : u(\sigma) \nsubseteq v(\sigma) \land \forall^\omega \tau \in (\overrightarrow{R} \cap R') : u(\tau) \nsubseteq v(\tau) \land \forall \tau \in (\hat{R} \cap \hat{R'}) : u(\tau) \nsubseteq v(\tau) .
\]

This is now reduced to a single \( \forall \text{PEP} \) instance by rewriting the \( \forall \text{PEP} \) into a \( \forall \text{PEP} \) (as said in the beginning of this proof) and relying on distributivity:

\[
\bigwedge_{i=1}^{n} \forall^\omega x \in X_i : \ldots \text{ same property } \ldots \equiv \forall^\omega \bigcup_{i=1}^{n} X_i : \ldots \text{ same } .
\]

6 Undecidability for \( \text{PEP}_{\text{co&dir}}^{\text{partial}} \) and other extensions

The decidability of \( \text{PEP}_{\text{partial codir}}^{\text{partial}} \) is a non-trivial generalization of previous results for PEP. It is a natural question whether one can further generalize the idea of partial directness and maintain decidability. In this section we describe two attempts that lead to undecidability, even though they remain inside the regular PEP framework.\[\dagger\]

\[\dagger\] PEP is undecidable if we allow constraint sets \( R \) outside \( \text{Reg}(\Sigma) \) [2]. Other extensions, like \( \exists x \in R_1 : \forall y \in R_2 : u(xy) \nsubseteq v(xy) \) for \( R_1, R_2 \in \text{Reg}(\Sigma) \), have been shown undecidable [6].
Allowing non-regular $R'$. One direction for extending $\text{PEP}_{\text{partial codir}}$ is to allow more expressive $R'$ sets for partial (co)directness. Let $\text{PEP}_{\text{partial [DCFL codir]}}$ and $\text{PEP}_{\text{partial [Pres codir]}}$ be like $\text{PEP}_{\text{partial codir}}$ except that $R'$ can be any deterministic context-free $R' \in \text{DCFL}(\Sigma)$ (respectively, any Presburger-definable $R' \in \text{Pres}(\Sigma)$), i.e., a language whose Parikh image is a Presburger, or semilinear, subset of $\mathbb{N}^{|\Sigma|}$). Note that $R \in \text{Reg}(\Sigma)$ is still required.

**Theorem 15. (Undecidability)** $\text{PEP}_{\text{partial [DCFL codir]}}$ and $\text{PEP}_{\text{partial [Pres codir]}}$ are $\Sigma^0_1$-complete.

Since both problems clearly are in $\Sigma^0_1$, one only has to prove hardness by reduction, e.g., from PCP, Post’s Correspondence Problem. Let $(\Sigma, \Gamma, u, v)$ be a PCP instance (where the question is whether there exists $x \in \Sigma^+$ such that $u(x) = v(x)$). Extend $\Sigma$ and $\Gamma$ with new symbols: $\Sigma \overset{\text{def}}{=} \Sigma \cup \{1,2\}$ and $\Gamma' \overset{\text{def}}{=} \Gamma \cup \{\#\}$. Now define $u', v': \Sigma^* \rightarrow \Gamma'$ by extending $u, v$ on the new symbols with $u'(1) = v'(2) = \varepsilon$ and $u'(2) = v'(1) = \#$. Define now $R = 12\Sigma^+$ and $R' = \{\tau \tau' \mid \tau, \tau' \in \Sigma^* \text{ and } u(\tau\tau') \neq v(\tau\tau')\}$. Note that $R'$ is deterministic context-free and Presburger-definable.

**Lemma 16. (See App. D)** The PCP instance $(\Sigma, \Gamma, u, v)$ has a solution if and only if the $\text{PEP}_{\text{partial [Pres codir]}}$ instance $(\Sigma', \Gamma', u', v', R, R')$ has a solution.

**Combining directness and codirectness.** Another direction is to allow combining directness and codirectness constraints. Formally, $\text{PEP}_{\text{co&dir}}$ is the problem of deciding, given $\Sigma$, $\Gamma$, $u$, $v$, and $R \in \text{Reg}(\Sigma)$ as usual, whether there exists $\sigma \in R$ such that $u(\sigma) \subseteq v(\tau)$ and $u(\tau') \subseteq v(\sigma')$ for all decompositions $\sigma = \tau \tau'$. In other words, $\sigma$ is both a direct and a codirect solution.

Note that $\text{PEP}_{\text{co&dir}}$ has no $R'$ parameter (or, equivalently, has $R' = \Sigma^*$) and requires directness and codirectness at all positions. However, this restricted combination is already undecidable:

**Theorem 17. (Undecidability)** $\text{PEP}_{\text{co&dir}}$ is $\Sigma^0_1$-complete.

Membership in $\Sigma^0_1$ is clear and we prove hardness by reducing from the Reachability Problem for length-preserving semi-Thue systems. The undecidability is linked to relying on different embeddings of $u(\sigma)$ in $v(\sigma)$ for the directness and codirectness. In contrast, for $\text{PEP}_{\text{partial dir}}$ we need to consider only the leftmost embedding of $u(\sigma)$ in $v(\sigma)$.

A semi-Thue system $S = (Y, \Delta)$ has a finite set $\Delta \subseteq Y^* \times Y^*$ of string rewrite rules over some alphabet $Y$, written $\Delta = \{l_1 \rightarrow r_1, \ldots, l_k \rightarrow r_k\}$. The one-step rewrite relation $\rightarrow_\Delta \subseteq Y^* \times Y^*$ is defined as usual with $x \rightarrow_\Delta y \overset{\text{def}}{=} x = zl' \text{ and } y = zr'$ for some rule $l \rightarrow r$ in $\Delta$ and strings $z, z'$ in $Y^*$. We write $x \rightarrow_\Delta m y$ when $x$ can be rewritten into $y$ by a sequence of $m$ (respectively, any number, possibly zero) rewrite steps.

The Reachability Problem for semi-Thue systems is “Given $S = (Y, \Delta)$ and two regular languages $P_1, P_2 \in \text{Reg}(Y)$, is there $x \in P_1$ and $y \in P_2$ s.t. $x \rightarrow_\Delta y$?”. It is well-known (or easy to see by encoding Turing machines in semi-Thue systems) that this problem is undecidable (in fact, $\Sigma^0_1$-complete) even when restricted to length-preserving systems, i.e., systems where $|l| = |r|$ for all rules $l \rightarrow r \in \Delta$.

We now construct a many-one reduction to $\text{PEP}_{\text{co&dir}}$. Let $S = (Y, \Delta)$, $P_1, P_2$ be a length-preserving instance of the Reachability Problem. W.l.o.g., we assume $\varepsilon \notin P_1$ and we restrict to reachability via an even and non-zero number of rewrite steps. With any such instance we associate a
PEP \text{co\&def} instance \( u, v : \Sigma^* \rightarrow \Gamma^* \) with \( R \in \text{Reg}(\Sigma) \) such that the following correctness property holds:

\[
\exists x \in P_1, \exists y \in P_2, \exists m \text{ s.t. } x^m \rightarrow_{\Delta} y \text{ (and } m > 0 \text{ is even} \) \iff \exists \sigma \in R \text{ s.t. } u(\tau) \subseteq v(\tau) \text{ and } u(\tau') \subseteq v(\tau') \text{ for all decompositions } \sigma = \tau \tau'.
\]

(CP)

The reduction uses letters like \( a, \) \( b \) and \( c \) taken from \( Y \), and adds \( \dagger \) as an extra letter. We use six copies of each such “plain” letter. These copies are obtained by priming and double-priming letters, and by overlining. Hence the six copies of a are \( a, a', a'', \bar{x}, \bar{a}, a'''. \) As expected, for a “plain” word (or alphabet) \( x \), we write \( x \) and \( \mathcal{T} \) to denote a version of \( x \) obtained by priming (respectively, overlining) all its letters. Formally, letting \( Y_\dagger \) being short for \( Y \cup \{ \dagger \} \), one has \( \Sigma = \Gamma \text{ def } Y_1 \cup Y_\dagger \cup Y''_1 \cup Y''_\dagger \cup Y'''_1 \cup Y'''_\dagger \).

We define and explain the reduction by running it on the following example:

\[
Y = \{ a, b, c \} \text{ and } \Delta = \{ ab \rightarrow bc, \text{ cc } \rightarrow \text{ aa} \}.
\]

(S\text{\text{\text{\text{\text{\text{example}}}}}})

Assume that \( abc \in P_1 \) and \( baa \in P_2 \). Then \( P_1 \rightarrow_{\Delta} P_2 \) since \( abc \rightarrow_{\Delta} baa \) as witnessed by the following (even-length) derivation \( \pi = \text{"abc} \rightarrow_{\Delta} \text{"bcc} \rightarrow_{\Delta} \text{"baa}" \). In our reduction, a rewrite step like \("abc} \rightarrow_{\Delta} \text{"bcc}" \) appears in the PEP solution \( \sigma \) as the letter-by-letter interleaving \( abc \mathcal{T} \mathcal{T} \mathcal{T} \), denoted \( abc \bigcup \bigcup \mathcal{T} \mathcal{T} \mathcal{T} \), of a plain string and an overlined copy of a same-length string.

Write \( T_\Delta(\Delta) \), or just \( T_\Delta \) for short, for the set of all \( x \bigcup \bigcup \Delta \) such that \( x \rightarrow_{\Delta} y \). Obviously, and since we are dealing with length-preserving systems, \( T_\Delta \) is a regular language, as seen by writing it as \( T_\Delta = (\sum_{a \in Y} a \mathcal{T})^* \cdot \{ \text{l } \bigcup \bigcup \text{l } | \text{l } \rightarrow_{\Delta} \text{r } \} \cdot (\sum_{a \in Y} a \mathcal{T})^* \), where \( \{ \text{l } \bigcup \bigcup \text{l } | \text{l } \rightarrow_{\Delta} \text{r } \} \) is a finite, hence regular, language.

\( T_\Delta \) accounts for odd-numbered steps. For even-numbered steps like \( \text{"bcc} \rightarrow_{\Delta} \text{"baa}" \) in \( \pi \) above, we use the symmetric \( \text{baa} \mathcal{T} \mathcal{T} \mathcal{T} \mathcal{T} \), i.e., \( \text{baa} \bigcup \bigcup \mathcal{T} \mathcal{T} \mathcal{T} \mathcal{T} \). Here too \( T_{\mathcal{T} \mathcal{T}} \) \( \text{def } \{ y \bigcup \bigcup x \mid x \rightarrow_{\Delta} y \} \) is regular. Finally, a derivation \( \pi \) of the general form \( x_0 \rightarrow_{\Delta} x_1 \rightarrow_{\Delta} \ldots \rightarrow_{\Delta} x_k \), where \( K \text{ def } |x_0| = \ldots = |x_k| \), is encoded as a solution \( \sigma_\pi \) of the form \( \sigma_\pi = \rho_0 \sigma_1 \rho_1 \sigma_2 \ldots \rho_{2k-1} \sigma_{2k} \rho_{2k} \) that alternates between the encodings of steps (the \( \sigma_i \)'s) in \( T_\Delta \cup T_{\mathcal{T} \mathcal{T}} \), and fillers, (the \( \rho_i \)'s) defined as follows:

\[
\sigma_i = \begin{cases} x_{i-1} \bigcup \bigcup x_i \\ x_i \bigcup \bigcup x_{i-1} \end{cases} \text{ for odd } i, \quad \rho_0 = x_0' \bigcup \bigcup \dagger \mathcal{K}, \rho_i = x_i'' \bigcup \bigcup \dagger \mathcal{K} \text{ for odd } i, \quad \rho_{2k} = x_k'' \bigcup \bigcup \dagger \mathcal{K}, \rho_{2k} = x_k'' \bigcup \bigcup \dagger \mathcal{K} \text{ for even } i \not= 0, 2k.
\]

Note that the extremal fillers \( \rho_0 \) and \( \rho_{2k} \) use double-primed letters, when the internal fillers use primed letters. Continuing our example, the \( \sigma_\pi \) associated with the derivation \( \text{"abc} \rightarrow_{\Delta} \text{"bcc} \rightarrow_{\Delta} \text{"baa}" \) is

\[
\sigma_\pi = (a'' \bigcup \bigcup b'' \bigcup \bigcup c'' \bigcup \bigcup a'' \bigcup \bigcup b'' \bigcup \bigcup c'' \bigcup \bigcup a'' \bigcup \bigcup b'' \bigcup \bigcup c'' \bigcup \bigcup a'' \bigcup \bigcup b'' \bigcup \bigcup c' \bigcup \bigcup a' \bigcup \bigcup b' \bigcup \bigcup c').
\]

The point with primed and double-primed copies is that \( u \) and \( v \) associate them with different images. Precisely, we define

\[
u(a) = a, \quad u(a') = \dagger, \quad u(\dagger') = \dagger, \quad u(a'') = \varepsilon, \quad u(\varepsilon') = \varepsilon,
\]

\[
u(a') = \dagger, \quad v(a') = a, \quad v(\dagger') = \varepsilon, \quad v(a'') = a, \quad v(\varepsilon') = \varepsilon.
\]

where \( a \) is any letter in \( Y \), and where \( w_Y \) is a word listing all letters in \( Y \). E.g., \( w_{\{ a, b, c \} } = abc \) in our running example. The extremal fillers use special double-primed letters because we want \( u(\rho_0) = \)}
u(ρ_{2k}) = ε (while v behaves the same on primed and double-primed letters). Finally, overlining is preserved by u and v: u(τ) \overset{\text{def}}{=} \overline{u(x)} and v(τ) \overset{\text{def}}{=} \overline{v(x)}.

This ensures that, for i > 0, u(σ_i) \subseteq v(ρ_{i-1}) and u(ρ_i) \subseteq v(σ_i), so that a σ_π constructed as above is a direct solution. It also ensures u(σ_i) \subseteq v(ρ_i) and u(ρ_{i-1}) \subseteq v(σ_i) for all i > 0, so that σ_π is also a codirect solution. One can check it on our running example by writing u(σ_π) and v(σ_π) alongside:

\[
\begin{array}{cccc}
\sigma_π &=& & \\
\rho_0 &=& a^n b^n c^n \overset{\text{def}}{=} & a^n b^n c^n \\
\rho_1 &=& & \\
\sigma_2 &=& & \\
\rho_2 &=& b^n a^n b^n a^n b^n & \\
\end{array}
\]

\[
\begin{array}{cccc}
u(\sigma_π) &=& \overset{\text{def}}{=} & \\
abbbccc &=& & \\
\uparrow\downarrow\uparrow\downarrow\uparrow\downarrow &=& & \\
bbaac &=& & \\
\end{array}
\]

There remains to define R. Since ρ_0 ∈ (Y^n)^+, since σ_i ∈ T_π for odd i, etc., we let

\[ R = \left( (Y^n)^+ \cdot T_π^{P_1} \cdot (\uparrow Y)^+ \cdot (T_π \cdot (Y^n)^+ \cdot T_π \cdot (\uparrow Y)^+ \cdot T_π \cdot (Y^n)^+ \right) \cdot T_π \cdot (Y^n)^+, \]

(1)

where T_π^{P_1} \overset{\text{def}}{=} \{ x \cup \emptyset \mid x \in P_1 \} = T_π \cap \{ x \cup \emptyset \mid x \in P_1 \} \mid x = \emptyset \} is clearly regular when P_1 is, and similarly for T_π^{P_2} \overset{\text{def}}{=} \{ y \cup \emptyset \mid y \in P_2 \}. Since σ_π ∈ R when π is an even-length derivation from P_1 to P_2, we deduce that the left-to-right implication in (CP) holds.

We refer to Appendix [1] for a proof that the right-to-left implication also holds, which concludes the proof of Theorem [17].

7 Concluding remarks

We introduced partial directness in Post Embedding Problems and proved the decidability of PEP_{partial}dir by showing that an instance has a solution if, and only if, it has a solution of length bounded by a computable function of the input. This generalizes and simplifies earlier proofs for PEP and PEP_{dir}. The added generality is non-trivial and leads to decidability for UCST, or UCS (that is, unidirectional channel systems) extended with tests [10]. The simplification lets us deal smoothly with counting or universal versions of the problem. Finally, we showed that combining directness and codirectness constraints leads to undecidability.

A Proof of the Length Function Theorem

Proof. The set of all $k$-controlled $n$-bad sequences ordered with the prefix ordering is a tree, with the empty sequence as root. (Note that any prefix of a $k$-controlled $n$-bad sequence is controlled and bad itself, so that our sequences correspond to paths from the root of the tree.) The tree has no infinite branches, otherwise we would read an infinite bad sequence along it, contradicting Higman’s Lemma. Furthermore the tree is finitely branching, since the sequences are $k$-controlled and $\Gamma$ is fixed. By König’s Lemma, the tree is then finite. We let $H(n,k,|\Gamma|)$ be the length of its longest branch. $H$ is computable since the tree can be constructed effectively from its root by listing the finitely many ways a current $n$-bad sequence can be extended in a $k$-controlled way.

The above $H$ is clearly monotonic, but anyone who doubts it can rather define

$$H'(n,k,s) \overset{\text{def}}{=} \max \{ H(n',k',s') \mid 0 \leq n' \leq n \land 0 \leq k' \leq k \land 0 \leq s' \leq s \}.$$ 

Finally, more elaborate notions of controlled sequences can be accommodated, as witnessed in [12], as long as the tree of controlled bad sequences is finitely branching.

B Missing proofs from Section 3

B.1 Proof of Lemma 1

Items 1 to 5 are easy (or see [2, Section 3]). Item 6 is proved by induction on $k$. The claim is true for $k = 1$, suppose it is true for $k = p$. Then $sx^{p+1} = sx^px \subseteq y^ptx \subseteq y^psx \subseteq y^pm\gamma = y^{p+1}m$. Item 7 is obtained from item 6 by mirroring.

B.2 Proof of Lemma 6: the sequence of left margins and the reversed sequence of right margins are $K_a$-controlled

We prove that $|l_{g_i}| \leq (i - 1) \times K_a$ by induction, showing $|l_{g_1}| = 0$ and $|l_{g_i}| - |l_{g_{i-1}}| \leq K_a$ for $i > 1$.

The base case $i = 1$ is easy: obviously $g_1 = 0$ since 0 is a blue index, and $l_0 = \varepsilon$ since it is the only suffix of $u_{0,0} = \varepsilon$, so that $|l_{g_1}| = 0$.

For the inductive step $i > 1$, we have two cases depending on whether $1 + g_{i-1}$ is blue or red. If $1 + g_{i-1}$ is blue, then $g_i = 1 + g_{i-1}$ and $l_{g_i}$ is a suffix of $l_{g_{i-1}}u(\sigma(g_i))$, so that $|l_{g_i}| \leq |l_{g_{i-1}}| + K_a$ which proves the claim.

If $1 + g_{i-1}$ is red, then all positions from $1 + g_{i-1}$ to $g_i - 1$ are red too, and $l_{g_i}$ is a suffix of $u(\sigma(g_i))$, so that $|l_{g_i}| \leq K_a$ which proves the claim.

The reasoning for $|r_{b_i}|$ is similar:

If $b_{i+1} = 1 + b_i$, then both $b_i$ and the next index are red. Then $r_{b_i}$ is a prefix of $u(\sigma(b_i))r_{b_{i+1}}$, so that $|r_{b_i}| \leq K_a + |r_{b_{i+1}}|$.

If $b_{i+1} > 1 + b_i$, then $b_i + 1$ is blue and $r_{b_i}$ is a prefix of $u(\sigma(b_i))$ so that $|r_{b_i}| \leq K_a$. In particular, since $N = \sigma$ is blue, $b_{N_2} < N$ and $|r_{b_{N_2}}| \leq K_a$.

Finally, $|r_{b_i}| \leq (N_2 + 1 - i) \times K_a$. 

C Missing proofs from Section[4]

C.1 Proof of Lemma[10] Iteration lemma for blue indices

PROOF. Let τ be any suffix of σ'. We show that u(τ) ⊆ v(τ) when τ ∈ R' or τ = σ', which will complete the proof. There are three cases, depending on how long τ is.

• τ is a suffix of σ[a,N]. Then τ is a suffix of σ itself, and this case is trivial since σ is a solution.

• τ is σ[i,b]σ[a,b]^pσ[b,N] for some p ≥ 1 and a < i ≤ b. Since a and b are congruent, τ ∈ R' implies σ[i,N] ∈ R'. Thus u_{i,N} ⊆ v_{i,N}, hence u_{i,b} ⊆ v_{i,b}s_b (since u_{b,N} ⊆ v_{b,N}). Then, using s_b ∩ s_a, Lemma[9] and s_bu_{b,N} ⊆ v_{b,N}, we get

\[ u(τ) = u_{i,b}(u_{a,b})^p u_{b,N} \subseteq v_{i,b}s_b(u_{a,b})^p u_{b,N} \subseteq v_{i,b}s_a(u_{a,b})^p u_{b,N} \]
\[ \subseteq v_{i,b}(v_{a,b})^p v_{b,N} = v(τ). \]

• τ is σ[i,a]σ[a,b]^kσ[b,N] for some 0 ≤ i < a. Since a and b are congruent, τ ∈ R' (or τ = σ) implies u_{i,N} ⊆ v_{i,N} so that u_{i,a} ⊆ v_{i,a}s_a as in the previous case. Then, using Lemma[5] and s_bu_{b,N} ⊆ v_{b,N}, we get

\[ u(τ) = u_{i,a}(u_{a,b})^k u_{b,N} \subseteq v_{i,a}s_a(u_{a,b})^k u_{b,N} \subseteq v_{i,a}(v_{a,b})^k s_b u_{b,N} \]
\[ \subseteq v_{i,a}(v_{a,b})^k v_{b,N} = v(τ). \]  

C.2 Proof of Lemma[11] Iteration lemma for red indices

Let τ be any suffix of σ'. We show that u(τ) ⊆ v(τ) when τ ∈ R' or τ = σ', which will complete the proof. There are three cases, depending on how long τ is.

• τ is a suffix of σ[a,N]. Then τ is a suffix of σ itself, and this case is trivial since σ is a solution.

• τ is σ[i,b]σ[a,b]^pσ[b,N] for some p ≥ 1 and a < i ≤ b. Since a and b are congruent, τ ∈ R' implies σ[i,N] ∈ R'. Thus u_{i,N} ⊆ v_{i,N}, hence u_{i,b}t_b ⊆ v_{i,b} since b is red. Using Lemma[5] again, we get u_{a,b}t_b ⊆ t_a v_{a,b}^p, and then (u_{a,b})^p t_b ⊆ t_a(v_{a,b})^p with Lemma[7]. Then

\[ u(τ) = u_{i,b}(u_{a,b})^p u_{b,N} \subseteq u_{i,b}(u_{a,b})^p t_b v_{b,N} \]
\[ \subseteq u_{i,b}t_a(v_{a,b})^p v_{b,N} \subseteq u_{i,b}t_a(v_{a,b})^p v_{b,N} \subseteq v_{i,b}(v_{a,b})^p v_{b,N} = v(τ). \]

• τ is σ[i,a]σ[a,b]^kσ[b,N] for some 0 ≤ i < a and k ≥ 1. Since a and b are congruent, τ ∈ R' (or τ = σ) implies u_{i,N} ⊆ v_{i,N} so that u_{i,a} ⊆ v_{i,a} as in the previous case. Then

\[ u(τ) = u_{i,a}(u_{a,b})^k u_{b,N} \subseteq u_{i,a}(u_{a,b})^k t_b v_{b,N} \subseteq u_{i,a}t_a(v_{a,b})^k v_{b,N} \subseteq v_{i,a}(v_{a,b})^k v_{b,N} = v(τ). \]  

C.3 Proof of Lemma[12] the reversed sequence of right margins and the sequence of left margins are K^∗,-controlled

We start with blue indices and right margins.

\footnote{with u = u_{a,b}, v = u_{b,N}, x = t_a v_{a,b}, t = v_{b,N}}
Lemma 18. Suppose \( a < b \) are two blue indices. Then \( s_i \) is a prefix of \( v_{a,b} s_b \).

Proof. Both \( s_a \) and \( v_{a,b} s_b \) are prefixes of \( v_{a,N} \), hence one of them is a proper prefix of the other. Assume, by way of contradiction, that \( v_{a,b} s_b \) is a proper prefix of \( s_a \). Say \( s_a = v_{a,b} s_b x \) for some \( x \neq \varepsilon \). Then \( s_a u_{a,N} \subseteq v_{a,N} \) rewrites as \( v_{a,b} s_b x u_{a,N} \subseteq v_{a,b} v_{b,N} \). Canceling \( v_{a,b} \) on both sides gives \( s_b x u_{a,N} = v_{b,N} \), i.e., \((s_b x u_{a,b}) u_{b,N} \subseteq v_{b,N} \), which contradicts the definition of \( s_b \).

We now show that \( s_{g_1}, \ldots, s_{g_1} \) is \( K_c \)-controlled. \( N \) is a blue index, and \(|s_N| = 0 \). For \( i \in [0,N] \), if both \( i \) and \( i + 1 \) are blue indices, then by Lemma 18, \(|s_i| \leq |s_{i+1}| + K_v \). If \( i \) is blue and \( i + 1 \) is red, then it is easy to see that \( s_i \) is a prefix of \( v(\sigma_i) \), and hence \(|s_i| \leq K_v \). So we get that \( s_{g_1}, \ldots, s_{g_1} \) is \( K_v \)-controlled.

Now to red indices and left margins. \( 0 \) is not a red index. For \( i \in [0,N] \), if both \( i \) and \( i + 1 \) are red, then it is easy to see that \( t_{i+1} \) is a suffix of \( t v(\sigma_i) \), and so \(|t_{i+1}| \leq |t_i| + K_v \). If \( i \) is blue and \( i + 1 \) is red, then \( t_{i+1} \) is a suffix of \( v(\sigma_i) \), and so \(|t_{i+1}| \leq K_v \). So we get that \( t_{b_1}, \ldots, t_{b_{b_2}} \) is \( K_v \)-controlled.

D Proof of Lemma 16

Suppose \( \sigma \) is a solution to the PCP problem. Then \( \sigma \neq \varepsilon \) and \( u(\sigma) = v(\sigma) \). Now \( \sigma' = 12 \sigma \) is a solution to the partially codirected problem since \( 12 \sigma \in R, u'(12 \sigma) = \# u(\sigma) \subseteq v'(12 \sigma) = \# v(\sigma) \), and \( \sigma' \) has no suffix in \( R' \) (indeed \( 2 \sigma \subseteq R' \) since \( u(\sigma) = v(\sigma) \)).

Conversely, suppose \( \sigma' \) is a solution to the partially codirected problem. Then \( \sigma' = 12 \sigma \) for some \( \sigma \neq \varepsilon \). Since \( u'(\sigma') = \# u(\sigma) \subseteq v'(\sigma') = \# v(\sigma) \), we have \( u(\sigma) \subseteq v(\sigma) \). If \( |u(\sigma)| \neq |v(\sigma)| \), then \( 2 \sigma \subseteq R' \), and so we must have \( u'(2 \sigma) = \# u(\sigma) \subseteq v'(2 \sigma) = v(\sigma) \). This is not possible as \( \# \) does not occur in \( v(\sigma) \). So \( |u(\sigma)| = |v(\sigma)| \), and \( u(\sigma) = v(\sigma) \). Finally, \( \sigma \) is a solution to the PCP problem.

E Undecidability of PEP_{co&dir}

In this section we prove the right-to-left half of Lemma 18 that states the correspondence of the reduction defined in the proof of Theorem 17.

Assume that there is \( \sigma \in R \) such that \( u(\tau) \subseteq v(\tau) \) and \( u(\tau') \subseteq v(\tau') \) for all decompositions \( \sigma = \tau \tau' \). By definition of \( R \) (see Eq. 1 on page 11), \( \sigma \in R \) must be of the form

\[
\rho_0 \sigma_1 \rho_1 (\sigma_2 \rho_2 \sigma_3 \rho_3) \cdots (\sigma_{2k-1} \rho_{2k-1} \rho_{2k-1} \sigma_{2k} \rho_{2k})
\]

for some \( k > 0 \), with \( \rho_0 \in (Y'' Y')^+ \), with \( \sigma_i \in T_\sigma \) for odd \( i \) and \( \sigma_i \in T_\sigma \) for even \( i \), etc. These \( 4k + 1 \) non-empty factors, \( (\sigma_i)_{1 \leq i \leq 2k} \) and \( (\rho_i)_{0 \leq i < 2k} \), are called the “segments” of \( \sigma \), and numbered \( s_0, \ldots, s_{4k} \) in order.

Lemma 19. \( u(s_{p}) \subseteq v(s_{p-1}) \) and \( u(s_{p-1}) \subseteq v(s_{p}) \) for all \( p = 1, \ldots, 4k \).

Proof. First note that the definition of \( u \) and \( v \) ensures that \( u(s_p) \) and \( v(s_p) \) use disjoint alphabets. More precisely, all \( u(\sigma_i)'s \) and \( v(\rho_i)'s \) are in \( (Y Y')^* \), while the \( v(\sigma_i)'s \) and the \( u(\rho_i)'s \) are in \( (Y Y')^* \), with the special case that \( u(\rho_0) = u(\rho_{2k}) = \varepsilon \) since \( \rho_0 \) and \( \rho_{2k} \) are made of double-primed letters.

Since \( \sigma \) is a direct solution, \( u(s_0 \ldots s_p) \subseteq v(s_0 \ldots s_p) \) for any \( p \), and even

\[
u(s_0 \ldots s_p) \subseteq v(s_0 \ldots s_p-1), \qquad (A_p)
\]
since \( v(s_p) \) has no letter in common with \( u(s_p) \). We now claim that, for all \( p = 1, \ldots, 4k \)

\[
u(s_0s_1 \ldots s_p) \nsubseteq v(s_0s_1 \ldots s_{p-2}), \quad (B_p)
\]
as we prove by induction on \( p \). For the base case, \( p = 1 \), the claim is just the obvious \( u(s_0s_1) \nsubseteq \varepsilon \). For the inductive case \( p > 1 \), one combines \( u(s_0 \ldots s_{p-1}) \nsubseteq v(s_0 \ldots s_{p-3}) \) (ind. hyp.) with \( u(s_p) \nsubseteq v(s_{p-2}) \) (different alphabets) and gets \( u(s_0 \ldots s_p) \nsubseteq v(s_0 \ldots s_{p-2}) \).

Combining \( (A_p) \) and \( (B_{p-1}) \), i.e., \( u(s_0 \ldots s_p) \subseteq v(s_0 \ldots s_{p-1}) \) and \( u(s_0s_1 \ldots s_{p-1}) \nsubseteq v(s_0s_1 \ldots s_{p-3}) \), now yields \( u(s_p) \nsubseteq v(s_{p-2}s_{p-1}) \), hence \( u(s_p) \nsubseteq v(s_{p-1}) \) since \( u(s_p) \) and \( v(s_{p-2}) \) share no letter: we have proved one half of the Lemma. The other half is proved symmetrically, using the fact that \( \sigma \) is also a codirect solution.

**Lemma 20.** \( |s_1| = |s_2| = \ldots = |s_{4k-1}| \).

**Proof (idea).** Since \( u(s_p) \subseteq v(s_{p-1}) \), the special form of the segments (from the definition of \( R \)) and the definition of \( u \) and \( v \) yield \( |s_p| \leq |s_{p-1}| \), hence \( |s_0| \geq |s_1| \geq \cdots \geq |s_{4k-1}| \). With the other half of Lemma 19, i.e., \( u(s_{p-1}) \subseteq v(s_p) \), one gets \( |s_1| \leq |s_2| \leq \cdots \leq |s_{4k}| \).

Now assume \( i \in \{1, \ldots, 2k\} \) is odd. By definition of \( R \), \( \sigma_i \in T_\bullet \) is some \( x_i-1 \uparrow y_i \) with \( x_i-1 \rightarrow_\Delta y_i \) and \( \sigma_{i+1} \in T_\bullet \) is some \( y_i+1 \downarrow x_i \) with \( x_i \rightarrow_\Delta y_{i+1} \). Furthermore, \( p_i \) is some \( x_i \uparrow |z_i| \downarrow y_i \). With Lemma 19 we deduce \( y_i \subseteq z_i \) and \( x_i \subseteq z_i \). With Lemma 20 we further deduce \( |y_i| = |z_i| = |x_i| \), hence \( y_i = x_i \). A similar reasoning shows that \( y_i = x_i \) also holds when \( i \) is even, so that the steps \( x_{i-1} \rightarrow_\Delta y_i \) can be chained. Finally, we deduce from \( \sigma \) the existence of a derivation \( x_0 \rightarrow_\Delta x_1 \rightarrow_\Delta \cdots \rightarrow_\Delta x_{2k} \). Since \( \sigma_0 \in T^{\neg P_1} \) and \( \sigma_{2k} \in T^{\neg P_2} \), we further deduce \( x_0 \in P_1 \) and \( x_{2k} \in P_2 \). Hence the existence of \( \sigma \) entails \( P_1 \nrightarrow_\Delta P_2 \), which concludes the proof.
