A sufficiently strong long-range Coulomb interaction can induce excitonic pairing in gapless Dirac semimetals, which generates a finite gap and drives semimetal-insulator quantum phase transition. This phenomenon is in close analogy to dynamical chiral symmetry breaking in high energy physics. In most realistic Dirac semimetals, including suspended graphene, Coulomb interaction is too weak to open an excitonic gap. The Coulomb interaction plays a more important role at low energies in a two-dimensional semi-Dirac semimetal, in which the fermion spectrum is linear in one component of momenta and quadratic in the other, than a Dirac semimetal, and indeed leads to breakdown of Fermi liquid theory. We study dynamical excitonic gap generation in a two-dimensional semi-Dirac semimetal by solving the Dyson-Schwinger equation, and show that a moderately strong Coulomb interaction suffices to induce excitonic pairing. Additional short-range four-fermion coupling tends to promote excitonic pairing. Among the available semi-Dirac semimetals, we find that TiO$_2$/VO$_2$ nanostructure provides a promising candidate for the realization of excitonic insulator. We also apply the renormalization group method to analyze the strong coupling between the massless semi-Dirac fermions and the quantum critical fluctuation of excitonic order parameter at the semimetal-insulator quantum critical point, and reveal non-Fermi liquid behaviors of semi-Dirac fermions.

I. INTRODUCTION

The past decade has witnessed the appearance of a huge amount of experimental and theoretical work on the physical properties of various semimetals, in which the valence and conduction bands touch at isolated points \[1–3\]. The low-energy elementary excitations in these semimetals are various types of massless fermions. The fermion density of state (DOS) vanishes at band-touching points, so the Coulomb interaction remains long-ranged. This is in sharp contrast to the ordinary metals featuring a finite Fermi surface, where Coulomb interaction becomes short-range due to static screening.

Graphene is a two-dimensional (2D) Dirac semimetal with massless Dirac fermions being its low-energy excitations \[4, 5\]. The surface state of three-dimensional (3D) topological insulator (TI) is also a 2D Dirac semimetal \[6\]. Apart from these two examples, there are also a number of other systems that support low-energy bulk massless Dirac or Weyl fermions. For instance, a 3D Dirac semimetal emerges at the quantum critical point (QCP) between a trivial band insulator and a topological insulator \[8–11\]. Moreover, stable 3D Dirac semimetal, protected by crystal symmetry, has been found to exist in Na$_3$Bi \[12\] and Cd$_3$As$_2$ \[13, 14\]. 3D Weyl semimetal, which hosts fermions with linear dispersion around pairs of Weyl points with opposite chirality, was observed in TaAs \[15, 16\], NbAs \[17, 18\], TaP \[19, 20\], and NbP \[21, 22\] by angle-resolved photoemission spectroscopy (ARPES) experiments. Several other types of semimetals, including 3D quadratic semimetal \[23, 24\], 3D anisotropic Weyl semimetal \[25, 26\], 3D double Weyl semimetal \[27, 28\], 3D nodal-line semimetal \[29–33\], and 2D semi-Dirac semimetal \[33, 34\], are also widely investigated.

The effects of long-range Coulomb interaction have been studied in various types of semimetals \[5, 34–52\]. The role of Coulomb interaction depends crucially on the fermion dispersion and the dimension. Extensive renormalization group (RG) analysis \[53\] have revealed that Coulomb interaction is marginally irrelevant in 2D Dirac semimetal \[5, 33–35\], 3D Dirac/Weyl semimetal \[36–41\], and also 3D double Weyl semimetal \[42, 43\]. The Fermi liquid (FL) theory is valid in 2D Dirac semimetal \[5\]. However, the Coulomb interaction cannot be simply neglected as it results in fermion velocity renormalization and logarithmic-like correction to some of the observable quantities \[5, 34, 59\]. Indeed, the predicted velocity renormalization has already been observed in ultra clean suspended graphene \[50\], quasi-free-standing graphene on silicon carbide (SiC) \[51\], and graphene on boron nitride substrate \[52\]. There is also experimental evidence for the renormalization of fermion dispersion in TI-like system of Bi bilayer grown on Bi$_2$Se$_3$ \[53, 54\], which seems to be caused by Coulomb interaction. In a 3D semimetal with quadratic dispersion, the Coulomb interaction is found to be relevant and cause non-Fermi liquid (NFL) behaviors \[42\]. It is interesting to notice that recent ARPES experiments have discovered NFL behavior in a 3D quadratic semimetal material Pr$_2$Ir$_2$O$_7$ \[64\]. Moreover, in a 3D anisotropic Weyl semimetal \[48\] and a 3D nodal-line semimetal \[51\], the FL description is robust because the Coulomb interaction is irrelevant.

In an interacting 2D Dirac fermion system, an in-
triguing property is that the strong Coulomb interaction might bind a gapless fermion and a gapless hole to form an excitonic pair, which generates a finite energy gap at the Dirac points and turns the Dirac semimetal into an excitonic insulator \[ E = \pm \sqrt{ak_x^4 + v^2k_y^2}, \] (1)

which is linear along one momentum component \( k_y \) but quadratic along the other one \( k_x \). Such fermions can emerge at the QCP between a 2D Dirac semimetal and a band insulator upon merging two separate Dirac points into a single one. Generating 2D semi-Dirac fermions by merging pairs of Dirac points was predicted to take place in deformed graphene \[ 102, 106 \], pressured organic compound \( \alpha-(BEDT-TTF)_2I_3 \) \[ 104, 106, 108 \], few-layer black phosphorus subject to pressure or perpendicular electric field \[ 103, 110 \], or doping \[ 111 \], and some sorts of artificial optical lattices \[ 112, 113 \]. Experimentally, the merging of distinct Dirac points and the appearance of semi-Dirac fermions were recently observed in ultracold Fermi gas of \( ^{40} \)K atoms in honeycomb lattice \[ 114 \], and microwave cavities with graphene-like structure \[ 115 \]. Kim et al. \[ 116 \] realized semi-Dirac semimetals in few-layer black phosphorus at critical surface doping with potassium. Robust semi-Dirac semimetal state was also predicted to appear in \( TiO_2/VO_2 \) nanostructure under suitable conditions \[ 117, 119 \]. It was suggested by first-principle calculations that semi-Dirac fermions may emerge in strained puckered arsenene \[ 120, 121 \].

The influence of long-range Coulomb interaction in 2D semi-Dirac fermion system was recently investigated by perturbative RG method to one-loop order \[ 34, 35 \], which showed that Coulomb interaction becomes anisotropic due to dynamical screening \[ 34, 35 \]. When the bare value of interaction strength \( \alpha \) is in the strong coupling regime, the Coulomb interaction induces an anomalous

According to theoretical analysis \[ 5, 65 \], an excitonic gap can be dynamically generated in zero external magnetic field only when the effective strength of Coulomb interaction, denoted by the parameter \( \alpha \), is larger than certain critical value. The critical value \( \alpha_c \) defines a QCP that separates the semimetallic and excitonic insulating phases. This issue has been most extensively studied in the context of undoped graphene \[ 5, 65, 66 \]. Physically, the excitonic insulating transition corresponds to the formation of a charge density wave (CDW) order \[ 5, 65 \]. If the ground state of suspended graphene is an excitonic insulator, there would be more practical applications of graphene in the design of electronic devices \[ 5, 66 \]. From a theoretic point of view, this provides an ideal laboratory to test some important concepts of high energy physics \[ 68 \], and also gives us a nice platform to study the rich quantum critical phenomena.

In graphene and other Dirac semimetals, the effective strength of Coulomb interaction can be quantified by the ratio between the Coulombic potential energy and kinetic energy of fermions, defined as \[ 5 \alpha = e^2/\epsilon c, \] where \( e \) is the electric charge, \( v \) fermion velocity, and \( \epsilon \) dielectric constant. Experiments have determined that the fermion velocity is \( v \approx c/300 \approx 10^6m/s \), where \( c \) is the speed of light in vacuum \[ 4, 5 \]. For graphene on SiO\(_2\) substrate, \( \alpha \approx 0.78 \). When graphene is suspended in vacuum, \( \alpha \) takes its largest value \( \alpha \approx 2.2 \) \[ 66 \], which implies that excitonic pairing is most possibly realized in suspended graphene. To specify whether suspended graphene has a semimetallic or insulating ground state, one needs to calculate the critical value \( \alpha_c \) and then compares it with \( \alpha \approx 2.2 \). The value of \( \alpha_c \) has been evaluated by means of several different methods, including Dyson-Schwinger (DS) equation \[ 65, 71, 89 \], Bethe-Salpeter (BS) equation \[ 84, 86 \], RG approach \[ 86, 89 \], Monte Carlo simulations \[ 90, 91 \], and some other methods \[ 93, 94 \]. Drut and Lähde claimed that \( \alpha_c \approx 1.1 \) in a 2D Dirac fermion system \[ 90, 91 \], which indicates that graphene placed on SiO\(_2\) substrate is semimetallic but suspended graphene is insulating at zero temperature. Extensive studies based on DS equation \[ 71, 72, 74, 75, 78 \], BS equation \[ 84, 85 \], and RG approach \[ 87, 88 \] all showed that \( \alpha_c < 2.2 \) and hence also predicted an insulating ground state of sus-

pended graphene. However, experiments clearly revealed that suspended graphene remains a semimetal down to very low temperatures, without any sign of insulating behavior \[ 60, 100 \], which is apparently inconsistent with earlier theoretical results. A number of improved studies \[ 79, 80, 82, 83, 90, 97 \] have been accomplished to reconcile this discrepancy. After taking into account the influence of fermion velocity renormalization and fermion damping, it was showed in a refined DS equation analysis \[ 75 \] that the critical value is \( \alpha_c \approx 3.25 \), which is much larger than \( \alpha = 2.2 \). Thus it turns out that the Coulomb interaction in suspended graphene is still not strong enough to generate a dynamical gap. Subsequent DS equation studies \[ 81, 82, 83 \] reached the same qualitative conclusion. After considering the screening of Coulomb interaction due to the \( \sigma \)-band electrons \[ 101 \], recent Monte Carlo simulations also found that \( \alpha_c \) is greater than 2.2 \[ 96, 97 \], which suggests a semimetallic ground state of suspended graphene.

Since graphene cannot be an excitonic insulator, we turn to consider other types of semimetal where the Coulomb interaction plays a more important role. Among the existing semimetal materials, we find that 2D semi-Dirac semimetal provides a better candidate for the realization of excitonic insulating transition than graphene. The dispersion for 2D semi-Dirac fermion is
dimension for fermions and produces NFL behaviors over a wide range of intermediate energies \[^3, 4, 34\]. This property is qualitatively similar to graphene \[^50\]. Regardless of the value of \(\alpha\), the fermion kinetic energy gets enhanced as the renormalized \(a\) and \(v\) increase with lowering energy. This then drives \(\alpha\) to flow to zero in the low-energy region very slowly, which means the Coulomb interaction in 2D semi-Dirac semimetal is marginally irrelevant. However, 2D semi-Dirac semimetal differs from graphene in one important aspect. In graphene, the quasiparticle quasimomentum is subject to a long-range Coulomb interaction, and thus the system displays a marginal Fermi liquid behavior in the lowest energy limit \(^3\). This difference indicates that the Coulomb interaction plays a more important role in 2D semi-Dirac semimetal than graphene. It might be possible to form excitonic insulator in some realistic 2D semi-Dirac semimetal.

Dynamical excitonic gap generation is a genuine non-perturbative phenomenon, and cannot be obtained within the framework of ordinary leading-order perturbative calculation \[^34, 35\]. In this paper, we study the possibility of dynamical gap generation in a 2D semi-Dirac semimetal by solving the self-consistent DS integral equation of the excitonic gap. The DS equation is formally very complicated, so it is usually necessary to make some approximations. After solving the DS equation by employing three frequently used approximations, we show that a moderately strong Coulomb interaction suffices to generate an excitonic gap, and that it is easier to realize an excitonic insulating state than in a 2D Dirac semimetal. Among the currently known semi-Dirac semimetals, the TiO\(_2\)/VO\(_2\) nanostructure is a particularly promising candidate to realize excitonic insulating state. One reason is that the such nanostructure is an intrinsic semi-Dirac fermion system, without necessity of fine tuning. The other reason is that the physical value of \(\alpha\) in this nanostructure is either smaller or very close to the critical value \(\alpha_c\) obtained in our DS equation calculations. Apart from the long-range Coulomb interaction, there may be some additional short-range four-fermion couplings in real materials. Adding such coupling to the system reduces the critical value \(\alpha_c\), and hence catalyzes dynamical excitonic gap generation.

In the insulating phase, the fermions are massive and the systems exhibits different properties than the semimetal phase. We calculate DOS and specific heat of the insulating phase, and compare them with those of semimetal phase. Moreover, we perform a systematic RG analysis of the Yukawa-type coupling between massless fermions and the quantum fluctuation of excitonic order parameter at the QCP of semimetal-insulator transition, and find NFL behaviors of massless fermions. We also study the interplay of this Yukawa coupling with long-range Coulomb interaction. In this case, the massless fermions still exhibit NFL behaviors, but some model parameters behave quite differently from those obtained in the case without Coulomb interaction.

The rest of the paper will be organized as follows. We present the Hamiltonians and the propagators in Sec. II

In Sec. III we derive the self-consistent gap equation, and numerically solve the gap equation in several different approximations which were employed in the studies of the excitonic gap equation in graphene. We compare our results for semi-Dirac semimetal and previous results for graphene carefully in this section. In Sec. IV we study the dynamical gap generation including long-range Coulomb interaction and additional four-fermion interaction. The impact of excitonic gap for several observable quantities and the NFL behaviors of the fermions at the QCP between semi-Dirac semimetal phase and excitonic insulating phase are shown in Sec. V. We summarize the main results in Sec. VI.

II. MODEL HAMILTONIAN

The Hamiltonian for free 2D semi-Dirac fermions is

\[
H_i = \sum_{\sigma=1}^{N} \int d^2x \psi^\dagger_\sigma(x) \left(-a \nabla_i^2 \tau_1 - iv \nabla_i \tau_2\right) \psi_\sigma(x),
\]

where \(\psi_\sigma\) represents the two-component spinor field with flavor index \(\sigma = 1, 2, 3, \ldots, N\), and \(\tau_1, \tau_2\) are standard Pauli matrices. The spinor \(\psi_\sigma\) can be written as \(\psi_\sigma = (\psi_A^\sigma, \psi_B^\sigma)^T\), where \(A\) and \(B\) are two sublattice indices \[^10\, 105, 12\]. Two model parameters \(a\) and \(v\) are introduced to characterize the fermion energy spectrum. The fermions are subject to a long-range Coulomb interaction, given by

\[
H_C = \frac{1}{4\pi} \sum_{\sigma=1}^{N} \int d^2x d^2x' \rho_\sigma(x) \frac{\epsilon^2}{|x - x'|} \rho_\sigma^*(x'),
\]

where the fermion density operator is defined as

\[
\rho_\sigma(x) = \psi^\dagger_\sigma(x) \psi_\sigma(x).
\]

The model will be treated by making perturbative expansion in powers of \(1/N\).

The free fermion propagator reads

\[
G_0(\omega, \mathbf{k}) = \frac{1}{-i\omega + ak_x^2 \tau_1 + ivk_y \tau_2}.
\]

The bare Coulomb interaction is written in the momentum space as

\[
V_0(\mathbf{q}) = \frac{2\pi e^2}{|\mathbf{q}|} = \frac{2\pi \alpha v}{|\mathbf{q}|},
\]

where \(\alpha = e^2/\epsilon v\) represents the effective interaction strength. After including the dynamical screening, the dressed Coulomb interaction function can be written as

\[
V(\Omega, \mathbf{q}) = \frac{1}{V_0^{-1}(\mathbf{q}) + \Pi(\Omega, \mathbf{q})},
\]
in which the polarization function $\Pi(\Omega, \mathbf{q})$ is given by

$$
\Pi(\Omega, \mathbf{q}) = -N \int \frac{d\omega}{2\pi} \frac{d^2k}{(2\pi)^2} \text{Tr} \left[ G_0(\omega, \mathbf{k}) \times G_0(\omega + \mathbf{q} + \mathbf{k}) \right] 
$$

(7)

to the leading order of $1/N$ expansion. It is technically quite difficult to obtain a complete analytical expression of $\Pi(\Omega, \mathbf{q})$. The recent work of Isobe et al. [34] found that $\Pi(\Omega, \mathbf{q})$ can be approximated by the expression

$$
\Pi(\Omega, q_x, q_y) = \frac{N}{v} \frac{d_x \alpha^{1/2} q_x^2}{(\Omega^2 + c_0 a^2 q_x^2 + v^2 q_y^2)^{1/4}} + \frac{N}{v} \frac{d_y \alpha^{-1/2} v q_y^2}{(\Omega^2 + c_0 a^2 q_x^2 + v^2 q_y^2)^{3/4}},
$$

(8)

which produces the precise analytical expressions of $\Pi(\Omega, \mathbf{q})$ in several different limits. In this expression, $d_x$, $d_y$, and $c_0$ are three constants:

$$
d_x = \frac{1}{8\sqrt{\pi}} \frac{\Gamma(3/4)}{\Gamma(9/4)}, \quad d_y = \frac{1}{8\sqrt{\pi}} \frac{\Gamma(5/4)}{\Gamma(7/4)},
$$

$$
c_0 = \left( \frac{2}{\sqrt{\pi}} \frac{\Gamma(3/4)}{\Gamma(9/4)} \right)^4.
$$

(9)

If the fermions dynamically acquire a finite mass $m$ due to Coulomb interaction, a new term will be added to the total Hamiltonian

$$
H_m = m \sum_{\sigma=1}^{N} \int \frac{d^2k}{(2\pi)^2} \left( \psi^\dagger_{A\sigma} \tau_3 \psi_{A\sigma} - \psi^\dagger_{B\sigma} \psi_{B\sigma} \right).
$$

(10)

It is easy to observe that the dynamically generated mass $m$ breaks the exchange symmetry between sublattices $A$ and $B$. Therefore, the excitonic gap leads to the formation of CDW state.

### III. DYSON-SCHWINGER EQUATION OF EXCITONIC GAP

Since excitonic gap generation is a non-perturbative phenomenon, it cannot be investigated by making ordinary perturbative calculations. This issue will be studied by analyzing the DS equation, which is non-perturbative in nature and provides an ideal tool of describing various phase transitions. Since Nambu and Jona-Lasinio [68], the DS equation approach has been widely applied to study DCSB in QCD [123, 124] and QED$_2$ [125, 127], and also in 3D quadratic semimetal [46]. These studies serve as a very useful starting point for further, improved analysis.

After making these approximations, we obtain the following non-linear integral equation of fermion mass

$$
m(\varepsilon, p_x, p_y) = \int \frac{d\omega}{2\pi} \frac{d^2k}{(2\pi)^2} \frac{1}{\omega^2 + a^2 k_x^2 + v^2 k_y^2 + m^2(\omega, k_x, k_y)} \times V(\varepsilon - \omega, p - k).
$$

(14)

The integration ranges for $k_x$ and $k_y$ are chosen as $k_x \in (-\Lambda_x, \Lambda_x)$ and $k_y \in (-\Lambda_y, \Lambda_y)$, respectively. It is usually sufficient to suppose that $\Lambda_x = \Lambda_y = \Lambda$, where $\Lambda$ is the unit of momenta, and $\nu\Lambda$ is the unit of energy. The solution is determined by three parameters: interaction strength $\alpha$, fermion flavor $N$, and a tuning parameter $\beta = e\Lambda/\nu$, where $\Lambda$ is a UV cutoff.

The above equation can be numerically solved by the iterative method. Due to the explicit breaking of Lorentz invariance by the Coulomb interaction and the anisotropic fermion dispersion, the fermion mass gap
\[ m(\varepsilon, p_x, p_y) \text{ depends on its three free variables separately. Therefore, the above gap equation is formally much more complicated than that in graphene, where the gap equation contains only two independent variables, namely } \varepsilon \text{ and } |p|. \] 

To make sure that our numerical iterations are under control, it is necessary to introduce further approximations to the above gap equation. In the DS equation studies of excitonic gap generation in graphene, there are three frequently used approximations: instantaneous approximation \[73\], Khveshchenko approximation \[74\], and Gamayun-Gorbar-Gusynin (GGG) approximation \[74\]. We shall numerically solve the DS equation \[14\] under these three approximations separately, and then compare the results to those obtained in the context of graphene \[63, 71, 72, 74\].

**A. Instantaneous approximation**

The instantaneous approximation is widely employed to simplify the self-consistent DS equation of dynamical fermion gap. It has been used in such 2D Dirac semimetal as graphene \[63, 69, 71, 72, 81\], 3D semimetal with quadratic touching points \[46\], and finite temperature QED \[131\]. A universal feature shared by these systems is that the fermion mass gap depends on energy and momentum separately due to the explicit breaking of Lorentz invariance, which makes it very difficult to solve the self-consistent gap equation numerically. In the instantaneous approximation, the energy-dependence of fermion gap is dropped, but the momentum-dependence is maintained. Under this approximation, the interaction function becomes

\[
V(\Omega, \mathbf{q}) \rightarrow V(\mathbf{q}) = \frac{1}{V_0^{-1}(\mathbf{q}) + \Pi(\mathbf{q})}
\]

\[
= \left[ \frac{|\mathbf{q}|}{2\pi \alpha v} + \frac{N}{v} \frac{d_\alpha a^{1/2} q_y^2}{(c_0 a^2 q_y^2 + v^2 q_y^2)^{1/4}} \right]^{-1}
+ \frac{N}{v} \frac{d_\beta a^{-1/2} v^2 q_y^2}{(c_0 a^2 q_y^2 + v^2 q_y^2)^{3/4}}. \quad (15)
\]

Accordingly, the gap equation \[14\] is simplified to

\[
m(p_x, p_y) = \frac{1}{2} \int \frac{d^2 \mathbf{k}}{(2\pi)^2} \frac{m(k_x, k_y)}{\sqrt{a^2 k_x^2 + v^2 k_y^2 + m^2(k_x, k_y)}} \times V(\mathbf{p} - \mathbf{k}) \quad (16).
\]

We show the dependence of \(m(0) = m(p_z = 0, p_y = 0)\) on \(\beta\) obtained for \(N = 2\) and \(N = 4\) in Fig. 1(a) and Fig. 1(b), respectively. It is apparent that \(m(0)\) exhibits a non-monotonic dependence on \(\beta\). As \(\beta\) grows, \(m(0)\) increases initially, but begins to decrease once \(\beta\) is greater than some critical value. The dependence of \(m(0)\) on parameter \(\alpha\) in the cases of \(N = 2\) and \(N = 4\) is presented.
in Fig. 2. We can clearly observe that $m(0)$ decreases as $\alpha$ is lowered, and eventually vanishes once $\alpha$ is smaller than a critical value $\alpha_c$. According to the results given in Fig. 2, it turns out that the critical value $\alpha_c$ is not very sensitive to the change in $\beta$. For a series of different values of $\beta$, ranging from 0.2 to 8, $\alpha_c \approx 0.6$ in the case of $N = 4$. In a 2D Dirac semimetal, the critical interaction strength obtained under instantaneous approximation is $\alpha_c \approx 2.33$ for $N = 4$ [65, 70]. An immediate indication is that the excitonic gap can be much more easily generated in a 2D semi-Dirac semimetal than a 2D Dirac semimetal.

For fixed values of $\alpha$ and $\beta$, there exists a critical fermion flavor $N_c$ that separates the semimetallic and excitonic insulating phases. As shown in Fig. 3, $m(0)$ decreases with growing $N$ and vanishes once $N$ exceeds $N_c$. Specifically, $N_c$ takes a finite value even in the infinitely strong coupling limit $\alpha \to \infty$. Thus, the flavor $N$ must be sufficiently small for an excitonic gap to be opened. Moreover, Fig. 2 tells us that, $N_c$ always falls in the range of $(6, 7)$ in the $\alpha \to \infty$ limit, which is valid for three representative values of $\beta$. As a comparison, we recall that $N_c = 8/\pi \approx 2.55$ in the limit $\alpha \to \infty$ in a 2D Dirac semimetal, which was obtained under the same approximation [65, 70]. This result provides further evidence that it is much easier to induce an excitonic gap in a 2D semi-Dirac semimetal than a 2D Dirac semimetal.

To acquire a more quantitative knowledge of the fermion gap, we present function $m(p_x, p_y)$ in Fig. 4. In the limit $p_{x,y} \to 0$, $m(p_x, p_y)$ approaches a finite value $m(0, 0)$. As $p_x$ or $p_y$ grows, $m(p_x, p_y)$ drops rapidly when
appears that \(m(p_x, p_y)\) exhibits a weak non-monotonic dependence on \(p_x\) in the intermediate range of energies, but \(m(p_x, p_y)\) decreases monotonously with growing \(p_y\). The strongly anisotropic behavior of \(m(p_x, p_y)\) clearly comes from the anisotropy in fermion dispersion.

B. Khveshchenko approximation

The instantaneous approximation entirely neglects the energy-dependence of the Coulomb interaction. In a 2D Dirac semimetal, after including one-loop polarization, the dressed Coulomb interaction becomes

\[
V_{\text{Dirac}} = \frac{1}{2 \pi \alpha v} + \frac{N |q|^2}{16 \sqrt{|q|^2 + |q|^2}}. \tag{17}
\]

Khveshchenko \cite{73} proposed an improved approximation

\[
V_{\text{Dirac}} \rightarrow \frac{1}{2 \pi \alpha v} + \frac{N |q|}{16 \sqrt{2}}, \tag{18}
\]

and then applied it to study dynamical gap generation in graphene \cite{72}. It was shown by Khveshchenko \cite{73} that \(\alpha_c \approx 1.13\) for \(N = 4\), which is much smaller than \(\alpha_c \approx 2.33\) obtained by using the instantaneous approximation. It was also found \cite{73} that \(N_c \approx 7.18\) in the strong coupling limit \(\alpha \rightarrow \infty\), which is much larger than \(N_c \approx 2.55\) obtained under instantaneous approximation. It is therefore clear that the energy dependence of Coulomb interaction plays an important role and needs to be seriously incorporated in the DS equation.

We now adopt the Khveshchenko approximation to study the DS gap equation in 2D semi-Dirac semimetal. The dressed Coulomb interaction function given by Eq. \(10\) is much smaller than \(\alpha_c \approx 1.13\) obtained in 2D Dirac semimetal under the same approximation \cite{73}. We thus see once again that it is easier for Coulomb interaction to open an excitonic gap in a 2D semi-Dirac semimetal. The relation between \(m(0)\) and \(N\) is presented in Fig. \(6\) (a) and (b) with \(\alpha = 0.1\) and \(\alpha = \infty\) respectively. By using the Khveshchenko approximation, it is found that \(m(0)\) vanishes once \(N\) is greater than some critical value, even in the strong coupling limit \(\alpha \rightarrow \infty\). As shown in Fig. \(5\) (a), \(N_c \approx 9\) with \(\beta = 1\) in the limit \(\alpha \rightarrow \infty\) under the Khveshchenko approximation, which is larger than \(N_c \approx 7.18\) obtained in the limit \(\alpha \rightarrow \infty\) under the same approximation in a 2D Dirac semimetal \cite{72}.
C. Gamayun-Gorbar-Gusynin approximation

In order to include the influence of energy dependence of Coulomb interaction on dynamical gap generation in 2D Dirac semimetal, Gamayun et al. \cite{73} introduced another approximation, which assumes the mass gap to be energy independent, namely

$$m(\varepsilon, \mathbf{p}) \rightarrow m(\mathbf{p}),$$

but retains the energy dependence of Coulomb interaction. Under the GGG approximation, they solved the DS equation and found that \(\alpha_c \approx 0.92\) for flavor \(N = 4\), which is clearly smaller than \(\alpha_c \approx 2.33\) obtained under the instantaneous approximation \[63, 70\]. This result provides another signature that the energy dependence of Coulomb interaction is in favor of dynamical excitonic gap generation. They also found that, in the strong coupling limit \(\alpha \rightarrow \infty\), the critical fermion flavor \(N_c \rightarrow \infty\), which is quite different from the results obtained under the instantaneous and Khveshchenko approximations.

In this subsection, we employ the GGG approximation to study the dynamical excitonic gap in 2D semi-Dirac semimetal. By applying this approximation, the DS gap equation \[14\] becomes

$$m(p_x, p_y) = \int \frac{d\omega \, d^2k}{2\pi(2\pi)^2} m(k_x, k_y) \times \frac{1}{\omega^2 + \alpha^2 k_x^4 + \nu^2 k_y^2 + m^2(k_x, k_y)} \times V(\omega, \mathbf{p} - \mathbf{k}).$$

In principle, the integration range of energy should be \(\omega \in (-\infty, \infty)\). In practical numerical computations, it is necessary to introduce a cutoff. We choose to integrate over energy within the range \((-\Lambda_\omega, \Lambda_\omega)\), where \(\Lambda_\omega\) is taken to be sufficiently large so that the magnitude of dynamical gap is nearly independent of varying \(\Lambda_\omega\). The relation between \(m(0)\) and \(\alpha\) with \(N = 4\) is shown in Fig. 5 by the triangular mark. In Fig. 5(a), (b), and (c), \(\beta\) equal to 1, 0.1, and 10 respectively. As shown in Fig. 5, \(m(0)\) calculated through Eq. \[21\] is clearly larger than the one obtained under instantaneous and Khveshchenko approximations, which indicates that energy dependence of Coulomb interaction enhances dynamical gap generation. For \(\beta = 1, 0.1, 10\), we find that \(\alpha_c < 0.2\), which is also much smaller than \(\alpha_c \approx 0.92\) obtained in a 2D Dirac semimetal \[74\]. It is also clear that an excitonic gap can be more easily opened by Coulomb interaction in a 2D semi-Dirac semimetal.

The dependence of fermion gap on \(N\) obtained at \(\alpha = 1\) is shown in Fig. 6(a), represented by the green line with triangular mark. The critical flavor \(N_c\) is much larger than that obtained under instantaneous and Khveshchenko approximations. In the infinitely strong coupling limit \(\alpha \rightarrow \infty\), we find that \(N_c\) goes to infinity. This stems from an infrared divergence that is owing to the singular contribution appearing in the regions of

\[aq_x^2 \ll \Omega\] and \(\nu q_y \ll \Omega\]. These results point towards the fact that the energy dependence of Coulomb interaction is in favor of dynamical gap generation.

As shown in Eq. \[6\], the first term of the denominator of dressed Coulomb interaction is the contribution from bare Coulomb interaction, and depends only on momentum \(|q|\). The second term arises from the dynamical screening due to collective particle-hole excitations, and is a function of energy \(\Omega\) and momenta \(q_x, q_y\). According to Eq. \[5\], it is easy to find that \(II(\Omega, q)\) is smaller than \(II(0, q)\). Therefore, the dressed Coulomb interaction becomes stronger after including the energy dependence, which tends to promote dynamical gap generation. Since \(II(\Omega, q)\) is proportional to \(N\), the difference between the fermion gaps obtained with and without the energy dependence of Coulomb interaction is more significant at larger \(N\). This property can be seen from the numerical results depicted in Fig. 6(a). Therefore, it is usually more important to incorporate the energy dependence of Coulomb interaction for larger values of \(N\).

It seems necessary to give a short summary here. We have numerically solved the DS equation under three widely used approximations. Although the precise value of \(\alpha_c\) is approximation dependent, we can infer from the extensive numerical solutions that \(\alpha_c\) obtained in a 2D semi-Dirac semimetal is much smaller than that of 2D Dirac semimetal. We thus conclude that a moderately strong Coulomb interaction suffices to open a finite excitonic gap in a 2D semi-Dirac semimetal.
As mentioned in Sec. II, there are indeed several possible ways to obtain a realistic 2D semi-Dirac semimetal. For instance, it can be created by merging two Dirac fermions at the QCP between a 2D Dirac semimetal and a trivial band insulator. Massless 2D semi-Dirac fermions also naturally emerge in a black phosphorus placed in a perpendicular electric field. However, in these cases the semi-Dirac semimetal is realized either by making a delicate tuning of some special parameter or by introducing an external field. It is therefore technically difficult to prepare a robust and intrinsic semi-Dirac semimetal in these materials. In contrast, an intrinsic 2D semi-Dirac semimetal can be more readily achieved in a TiO$_2$/VO$_2$ nanostructure, which was proposed by Pardo and his collaborators [117–119].

We now estimate the actual value of the interaction parameter $\alpha$. In VO$_2$, the fermion velocity is roughly $v_F \approx 1.5 \times 10^5$ m/s [117], and the fermion flavor is $N = 4$. The value of $\alpha$ relies crucially on the dielectric constant $\varepsilon$. In VO$_2$, the constant $\varepsilon \approx 36$ at room temperature, and increases with growing temperature [132]. It was predicted [117] that $\alpha \approx 0.41$ in VO$_2$ at room temperature. At lower temperatures, the value of $\varepsilon$ can be made even smaller than 36, which then gives rise to a value of $\alpha$ that is larger than $\alpha \approx 0.41$. The value of $\varepsilon$ can also be further tuned by other non-thermal scenarios, such as substrate. Our DS equation calculations have shown that the critical parameter $\alpha_c \approx 0.6$, $\alpha_c \approx 0.3 \sim 0.4$, and $\alpha_c < 0.2$ under the instantaneous, Khveschenko, and GGG approximations, respectively. We can see that the actual value of $\alpha$ at room temperature is already smaller or close to the critical value $\alpha_c$. At nearly zero temperatures, the physical value of $\alpha$ might become much larger than 0.41. We thus predict that the TiO$_2$/VO$_2$ nanostructure is an ideal candidate to realize excitonic insulator, which can be probed by ARPES [133] or other experiments [64, 134].

IV. ADDITIONAL SHORT-RANGE FOUR-FERMION COUPLING

Besides the long-range Coulomb interaction, there may be additional short-range four-fermion couplings [5, 72]. In this section, we study the impact of such short-range couplings on dynamical excitonic gap generation. In principle, there are a number of possible four-fermion couplings. Their roles can be classified by the symmetry and also the (ir)relevance of these coupling terms. Here, we shall not consider all of the possible coupling terms, but focus on the most simple one:

\[
H_{FF} = \frac{g}{N} \sum_{\sigma=1}^{N} \int d^2 x \left( \psi_{\sigma}^\dagger(x) \tau_3 \psi_\sigma(x) \right)^2,
\]  
(22)

where $g$ is the quartic coupling constant. A simple power counting shows that the four-fermion interaction is irrelevant in the low-energy regime, which results from the vanishing of fermion DOS at Fermi level. After performing RG calculations at the one-loop level, we find that the four-fermion coupling is irrelevant if its initial value is small. However, it becomes relevant when its initial value is sufficiently large, which is usually interpreted as the generation of an excitonic order parameter $\langle \psi^\dagger \tau_3 \psi \rangle \neq 0$. Comparing to Eq. (10), we see that the four-fermion coupling shown in Eq. (22) generates the same order parameter as the one induced by Coulomb interaction. This is the reason why we consider the additional four-fermion coupling given by Eq. (22). This strategy was previously utilized in the studies of excitonic gap generation in graphene [74].

If we ignore the Coulomb interaction and retain the above four-fermion coupling solely, the gap equation takes the form

\[
\frac{1}{2g} = \int \frac{d\omega}{(2\pi)} \frac{d^2 k}{(2\pi)^2} \frac{1}{\omega^2 + a^2 k_x^4 + v^2 k_y^2 + m^2},
\]  
(23)

where $m$ is supposed to be a constant. Integrating over $\omega$, the gap equation can be further written as

\[
\frac{1}{g} = \int \frac{d^2 k}{(2\pi)^2} \frac{1}{\sqrt{a^2 k_x^4 + v^2 k_y^2 + m^2}}.
\]  
(24)

By setting $m = 0$, we find a critical strength $g_c$ that is

FIG. 7: (a) Dependence of $g_c$ on $\beta$. (b) Dependence of $m(0)$ on $g$ at different values of $\beta$. Only the four-fermion interaction is considered in this case.
The fermions remain massless if \( g < g_c \), but become massive once \( g \) exceeds \( g_c \). The critical value \( g_c \) is a function of the parameter \( \beta \), and the dependence of \( g_c \) on \( \beta \) is shown in Fig. 7(a). It is clear that \( g_c \) is an increasing function of \( \beta \), with \( g_c \to 0 \) when \( \beta \to 0 \). As shown in Fig. 7(b), the fermion mass \( m \) increases as \( g \) grows from a critical value \( g_c \).

We then incorporate both long-range Coulomb interaction and short-range four-fermion interaction, and obtain the following gap equation:

\[
\frac{1}{y_c} = \int \frac{d^2k}{(2\pi)^2} \frac{1}{\sqrt{a^2k_x^4 + v^2k_y^2}}.
\]

The fermions remain gapless if \( g < g_c \), but become massive once \( g \) exceeds \( g_c \). The critical value \( g_c \) is a function of the parameter \( \beta \), and the dependence of \( g_c \) on \( \beta \) is shown in Fig. 7(a). It is clear that \( g_c \) is an increasing function of \( \beta \), with \( g_c \to 0 \) when \( \beta \to 0 \). As shown in Fig. 7(b), the fermion mass \( m \) increases as \( g \) grows from a critical value \( g_c \).

We then incorporate both long-range Coulomb interaction and short-range four-fermion interaction, and obtain the following gap equation:

\[
m(p_x, p_y) = \frac{1}{2} \int \frac{d^2k}{(2\pi)^2} \frac{1}{\sqrt{a^2k_x^4 + v^2k_y^2 + m^2(k_x, k_y)}} \
\times V(p - k) \
+ g \int \frac{d^2k}{(2\pi)^2} \frac{1}{\sqrt{a^2k_x^4 + v^2k_y^2 + m^2(k_x, k_y)}}.
\]

where the instantaneous approximation has been adopted to simplify numerical calculations. The momentum cutoff is chosen in the same way as described below Eq. (14).

The dependence gap including both of long-range Coulomb interaction and four-fermion interaction is shown in Fig. 8. We observe that, in the presence of additional four-fermion coupling, the magnitude of excitonic gap is enhanced and the critical value \( \alpha_c \) is lowered. If the system contains only four-fermion coupling, there is a critical value \( g_c(\beta) \). When both Coulomb and four-fermion interactions are present, \( \alpha_c \) takes a finite value smaller than that obtained in the absence of four-fermion coupling, provided that \( g < g_c(\beta) \). In the special case of \( g > g_c(\beta) \), we find that \( \alpha_c = 0 \), so an arbitrary weak Coulomb interaction makes an important contribution to excitonic pairing.

![FIG. 8: Dependence of \( m(0) \) on \( \alpha \) at different values of \( g \). Both the Coulomb and four-fermion interactions are present. It is clear that larger \( g \) leads to larger gap.](image)

| \( g(\nu/\Lambda) \) | \( \frac{g}{\nu(\Lambda)} = 0 \) | \( \frac{g}{\nu(\Lambda)} = 1 \) | \( \frac{g}{\nu(\Lambda)} = 2 \) | \( \frac{g}{\nu(\Lambda)} = 3 \) |
|------------------|------------------|------------------|------------------|------------------|
| \( \alpha = 1 \) | \( 1.19 \times 10^{-2} \) | \( 4.54 \times 10^{-2} \) | \( 1.31 \times 10^{-1} \) | \( 2.55 \times 10^{-1} \) |
| \( \alpha = 2 \) | \( 8.43 \times 10^{-1} \) | \( 1.84 \times 10^{-1} \) | \( 3.2 \times 10^{-1} \) | \( 4.68 \times 10^{-1} \) |

**TABLE I:** Dynamical gap \( m(0) \) evaluated by adopting the GGG approximation in the presence of both Coulomb interaction and four-fermion coupling. Here, \( N = 4 \) and \( \beta = 1 \).

In this section, we have utilized the instantaneous approximation to solve the DS equation. The conclusion that dynamical gap generation is enhanced by additional four-fermion coupling is still valid when the energy dependence of Coulomb interaction is taken into account. This conclusion is confirmed by the pertinent numerical results presented in Table I.

## V. QUANTUM CRITICAL PHENOMENA

**EMERGENT AT INSULATING TRANSITION**

Once an excitonic gap is opened at the Fermi level, the semi-Dirac semimetal is converted to an insulator. In order to explicitly see the difference between semimetallic and insulating phases, we shall compute two important quantities, namely fermion DOS and specific heat, in this section. At a given flavor \( N \) and fixed \( \beta \), the insulating quantum phase transition happens at the QCP \( \alpha_c \). A bosonic order parameter \( \phi \) develops a nonzero mean value continuously as \( \alpha \) becomes larger than \( \alpha_c \). At such QCP, the semi-Dirac fermions and the excitonic order parameter are gapless, and can strongly affect each other. In this case, one cannot simply integrate out the fermionic degrees of freedom [133, 136]. Instead, one should maintain gapless fermions and gapless bosonic order parameter in an effective action, and study the Yukawa coupling between them [137, 142]. In this section, we perform a RG analysis of this coupling, and examine whether the system exhibits NFL behaviors at the QCP.

### A. DOS and specific heat in insulating phase

The dynamically generated fermion gap \( m \) manifests itself in several observable quantities, among which we are mainly interested in fermion DOS and specific heat. In order to make analytic computation simpler, we assume a constant gap \( m \). After including \( m \), the retarded fermion propagator is written in the form

\[
G^R(\omega, k) = \frac{-1}{\omega - ak_x^2\tau_1 - v k_y \tau_2 - m \tau_3 + i\eta}.
\]

The spectral function is given by

\[
A(\omega, k) = \frac{1}{\pi} \text{Tr} \left[ \text{Im} \left[ G^R(\omega, k) \right] \right] = 2|\omega|\delta \left( \omega^2 - (a^2k_x^4 + v^2k_y^2 + m^2) \right).
\]
The DOS can be computed from spectral function:

\[
\nu(\omega) = N \int \frac{d^2 k}{(2\pi)^2} A(\omega, k) = \frac{K \left( \frac{\omega}{T} \right) N}{\sqrt{2\pi^2 \sqrt{\alpha v}} (\omega^2 - m^2)^{\frac{1}{2}}} \theta (|\omega| - m),
\]

where \( K(x) \) is complete elliptic integrals of the first kind. It is easy to see that DOS is significantly suppressed by the finite gap in the low-energy regime.

To compute specific heat, we find it convenient to work in the Matsubara Green function formalism. The Matsubara propagator of massive semi-Dirac fermions is

\[
G(\omega_n, k) = \frac{1}{-i\omega_n + ak_\parallel^2 \tau_1 + v k_y \tau_2 + m \tau_3} = \frac{i\omega_n + ak_\parallel^2 \tau_1 + v k_y \tau_2 + m \tau_3}{(\omega_n^2 + a^2 k_\parallel^2 + v^2 k_y^2 + m^2)},
\]

where \( \omega_n = (2n + 1)\pi T \) with \( n \) being integers. Accordingly, the free energy takes the form

\[
F(T) = 2NT \sum_n \int \frac{d^2 k}{(2\pi)^2} \ln \left[ \left( \omega_n^2 + E_k^2 + m^2 \right)^{\frac{1}{2}} \right]
\]

with \( E_k = \sqrt{a^2 k_\parallel^2 + v^2 k_y^2} \). After carrying out the summation over imaginary frequency \( \omega_n \), we obtain

\[
F(T) = -4NT \int \frac{d^2 k}{(2\pi)^2} \ln \left[ 1 + e^{-\frac{\sqrt{\omega_n^2 + m^2}}{\lambda T}} \right],
\]

where a temperature independent term has been dropped. The specific heat is connected to the free energy through the relation:

\[
C_V(T) = -T \frac{\partial^2}{\partial T^2} F(T).
\]

In the gapless semimetallic phase with \( m = 0 \), \( C_V(T) \) depends on temperature as

\[
C_V(T) = \frac{15\sqrt{2}}{16\pi^2} (4 - \sqrt{2}) K \left( \frac{\omega}{T} \right) \zeta \left( \frac{5}{2} \right) \frac{N}{\sqrt{\alpha v} T^\frac{7}{2}},
\]

where \( \zeta(x) \) is the Riemann zeta function. In the insulating phase with \( m \neq 0 \), \( C_V(T) \) is strongly suppressed by fermion gap comparing to the semimetallic phase. In particular, in the limit \( m \gg T \), \( C_V(T) \) is given by

\[
C_V(T) \approx \frac{4\sqrt{2}K \left( \frac{\omega}{T} \right)}{3\pi^2} \frac{N m^\frac{7}{2}}{\sqrt{\alpha v} T^2} e^{-\frac{m}{T}},
\]

which decreases rapidly with lowering \( T \).

From Eq. [28] and Eq. [33], we observe that both DOS and specific heat are significantly suppressed in the low-energy region in the insulating phase.

### B. Non-Fermi liquid behaviors at semimetal-insulator QCP

In this subsection, we analyze the interaction between the quantum fluctuation of bosonic order parameter \( \phi \) and the gapless semi-Dirac fermions, which is described by a Yukawa-type coupling:

\[
S_{fb} = \lambda_0 \sum_{\sigma=1}^{N} \int dt d^2 x \phi_{\sigma}^\dagger \tau_3 \psi_{\sigma}.
\]

where \( \lambda_0 \) is the coupling coefficient. The free action of \( \phi \) takes the standard form

\[
S_{\phi} = \int d^2 x \left[ \frac{1}{2} (\partial_t \phi)^2 + \frac{\kappa}{2} (\nabla \phi)^2 + \frac{r}{2} \phi^2 + \frac{u_0}{24} \phi^4 \right]
\]

where the varying parameter \( r \) tunes the excitonic insulating transition with \( r = 0 \) being QCP. The free propagator of \( \phi \) is given by

\[
D_{\phi}(\omega, q) = \frac{1}{\omega^2 + \kappa q^2 + r}.
\]

Following the treatment of Ref. [141], we now make the replacements: \( \phi \to \phi/\lambda_0 \) and \( r \to r \lambda_0^2 \). Performing such a re-scaling manipulation leads to

\[
S_{fb} = \sum_{\sigma=1}^{N} \int dt d^2 x \phi_{\sigma}^\dagger \tau_3 \psi_{\sigma}.
\]

It is important to remember that both \( \phi \) and \( \psi \) particles are gapless at QCP. The quantum critical behaviors cannot be studied within the Hertz-Millis theory [135, 136]. Alternatively, we need to treat \( \phi \) and \( \psi \) on an equal footing and carefully study their coupling [137–142]. We now perform a detailed RG analysis of this coupling by employing a \( 1/N \) expansion, and examine whether the fermions exhibit NFL behaviors.

At the QCP with \( r = 0 \), including the polarization function contributed from fermions leads to the following propagator for \( \phi \) field:

\[
D(\Omega, q) = \frac{1}{\omega^2 + \kappa q^2 + \Pi_{33}(\Omega, q)},
\]

where the polarization \( \Pi_{33} \) is given by

\[
\Pi_{33}(\Omega, q) = N \int \frac{d\omega}{2\pi} \int \frac{d^2 k}{(2\pi)^2} \text{Tr} \left[ \tau_3 G_0(\omega, k) \tau_3 \times G_0(\omega + \Omega, k + q) \right]
\]

to the leading order of \( 1/N \) expansion. After straightforward calculations, which are presented in Appendix A, we find that \( \Pi_{33} \) can be approximated by

\[
\Pi_{33}(\Omega, q) = \frac{N}{\sqrt{\alpha v}} \left[ b_1 (\Omega^2 + v^2 q_y^2) + b_2 a^2 q_z^4 \right]^\frac{1}{4},
\]

where \( b_1 \) and \( b_2 \) are constants.
The expressions of constants $b_1$ and $b_2$ are two constants. In the low-energy regime, $\Pi_{33}$ dominates over the free term of $\phi$. We then drop the free term, and write the propagator as

$$D(\Omega, \mathbf{q}) = \frac{1}{\Pi_{33}(\Omega, \mathbf{q})}.$$  \hspace{1cm} (42)

The leading-order fermion self-energy induced by the Yukawa coupling is

$$\Sigma_{fb}(\omega, \mathbf{k}) = \int' \frac{d\Omega}{2\pi} \frac{d^2 \mathbf{q}}{2(2\pi)^2} \tau_3 G_0(\omega + \Omega, \mathbf{k} + \mathbf{q}) \times \tau_3 D(\Omega, \mathbf{q}).$$  \hspace{1cm} (43)

Here, the integration $\int' \frac{d\Omega}{2\pi} \frac{d^2 \mathbf{q}}{2(2\pi)^2}$ is made by choosing a suitable momentum shell for some related parameter. To be specific, we now employ the following RG scheme:

$$-\infty < \Omega < \infty, \quad b\Lambda < E_q < \Lambda,$$  \hspace{1cm} (44)

where $E_q = \sqrt{a^2 q_x^2 + \psi^2 q_y^2}$, and $b = e^{-l}$ with $l$ being a running length scale. According to Appendix B, the fermion self-energy takes the approximate form

$$\Sigma_{fb}(\omega, \mathbf{k}) \approx \left[ -i\omega C_1 + ak_x^2 C_2 \tau_1 + v k_y C_3 \tau_2 \right] \ln(b^{-1}).$$  \hspace{1cm} (45)

The expressions of constants $C_{1,2,3}$ are presented in Eqs. (B14)-(B16). Numerical calculation leads us to

$$C_1 \approx -\frac{0.0434929}{N},$$
$$C_2 \approx -\frac{0.00149482}{N},$$
$$C_3 \approx -\frac{0.0434929}{N}.$$  \hspace{1cm} (46-48)

Here notice that $C_1 = C_3$.

We now proceed to derive the RG equations. The action of free semi-Dirac fermions is

$$S_{\psi} = \int \frac{d\omega}{2\pi} \frac{dk_x}{2\pi} \frac{dk_y}{2\pi} \psi^\dagger(\omega, \mathbf{k}) \left(-i\omega + ak_x^2 \tau_1 + v k_y \tau_2\right) \psi(\omega, \mathbf{k}).$$  \hspace{1cm} (49)

We then make the following scaling transformations:

$$k_x = k_x' e^{-l},$$
$$k_y = k_y' e^{-l},$$
$$\omega = \omega' e^{-l},$$
$$\psi = \psi' e^{(\frac{\omega}{\Lambda} + C_2 \tau_1)} l,$$
$$a = a'e^{(C_2 - C_3 \tau_1)} l,$$
$$v = v'e^{(C_3 - C_1 \tau_1)} l.$$  \hspace{1cm} (50-57)

Now the action is recast in the form

$$S_{\psi'} = \int \frac{d\omega'}{2\pi} \frac{dk'_{x}}{2\pi} \frac{dk'_{y}}{2\pi} \psi'^\dagger(\omega', \mathbf{k}') \left(-i\omega' + a' k_x'^2 \tau_1 + v' k_y' \tau_2\right) \psi'(\omega', \mathbf{k'}),$$  \hspace{1cm} (58)

which is formally the same as the action of free fermions. According to Eq. (55), the RG equation for wave function renormalization $Z_f$ satisfies

$$\frac{dZ_f}{dl} = C_f Z_f.$$  \hspace{1cm} (59)

Based on Eqs. (50) and (57), we derive the RG equations for $a$ and $v$:

$$\frac{da}{dl} = (C_1 - C_2)a,$$
$$\frac{dv}{dl} = (C_1 - C_3)v.$$  \hspace{1cm} (60-61)

Solving the above three RG equations, we obtain

$$Z_f = Z_{f0} e^{C_1 l},$$
$$a = a_0 e^{(C_1 - C_2) l},$$
$$v = v_0,$$  \hspace{1cm} (62-64)

where $Z_{f0} = 1$. In the long wavelength limit $l \to \infty$, it is easy to find that $Z_f$ and $a$ both flow to zero, whereas $v$ does not flow and remains a constant. The behavior $\lim_{l \to \infty} Z_f \to 0$ clearly indicates the breakdown of FL theory. The wave function renormalization $Z_f$ can also be obtained from the identity:

$$Z_f(\omega) = \frac{1}{\left|1 - \frac{\partial}{\partial \omega} \text{Re} \Sigma^R(\omega)\right|},$$  \hspace{1cm} (65)

where $\Sigma^R(\omega)$ is the retarded fermion self-energy function. Combining Eqs. (62) and (65), and then using the scaling relationship $\omega = \omega_0 e^{-l}$, one can find that

$$\text{Re} \Sigma^R(\omega) \sim \omega^{1-n_f},$$  \hspace{1cm} (66)

where $n_f = -C_1$ is a positive quantity. By virtue of Kramers-Kronig (KK) relation, it is easy to obtain

$$\text{Im} \Sigma^R(\omega) \sim \omega^{1-n_f},$$  \hspace{1cm} (67)

which is apparently typical NFL behavior.
We present a schematic phase diagram in Fig. 9 for 2D interacting semi-Dirac fermion system on the plane spanned by $\alpha$ and $T$, with $\alpha_c$ defining the semimetal-insulator QCP. The system stays in the gapless semimetal phase for $\alpha < \alpha_c$, and becomes an excitonic insulator for $\alpha > \alpha_c$. The fermions exhibit NFL behaviors at zero-temperature QCP $\alpha_c$, which becomes a finite quantum critical region at finite temperature.

RG method has recently been applied to study the influence of Coulomb interaction in several semimetals which are distinguished mainly by the fermion dispersions \[34, 48, 49, 50]. In a 3D anisotropic Weyl semimetal where the spectrum displays quadratic dependence on momentum in one direction but linear dependence on other components of momenta, Yang et al. supposed a shell of ($b\Lambda, \Lambda$) for the integration over the quadratic component of momenta \[48]. Lai \[49] used the similar RG scheme to examine the impact of Coulomb interaction in a 3D double Weyl semimetal, in which the dispersion is quadratic in two components of momenta but linear in the third component. Different from Lai \[49], Jian and Yao \[50] considered the same model but made use of a different RG scheme which defines the momentum shell by $b\Lambda < E_k < \Lambda$ with $E_k = \sqrt{\frac{1}{a_m} (k_2^2 + k_y^2)^2 + v^2 k_2^2}$. There are some differences between the results obtained by Lai \[49] and Jian and Yao \[50]. When studying the role of Coulomb interaction in a 2D semi-Dirac semimetal, Isobe et al. \[34] introduced a shell for energy $b\Lambda < \Omega < \Lambda$, whereas Cho and Moon \[35] defined a shell for the linearly dependent momentum component.

Since recent studies showed that different RG schemes may result in quantitative differences \[49, 50], it is important to carry out RG calculations by employing several possible RG schemes and testify the reliability of our RG results. In the present problem, we also consider the following three RG schemes:

\[
\int^t_{\omega, q} = \int_{-\infty}^{+\infty} d\Omega \left( \int_{-\Lambda}^{-b\Lambda} dq_x \int_{-\infty}^{+\infty} dq_y, \right. \tag{68}
\]

\[
\int^t_{\omega, q} = \int_{-\infty}^{+\infty} d\Omega \int_{-\infty}^{+\infty} dq_x \left( \int_{-\Lambda}^{-b\Lambda} dq_y + \int_{b\Lambda}^{\Lambda} dq_y, \right. \tag{69}
\]

\[
\int^t_{\omega, q} = \left( \int_{-\Lambda}^{-b\Lambda} dq_x + \int_{b\Lambda}^{\Lambda} dq_x \right) \int_{-\infty}^{+\infty} d\Omega \int_{-\infty}^{+\infty} dq_y. \tag{70}
\]

where $\int^t_{\omega, q} = \int d\omega d^2q$. For convenience, we hereinafter use RG scheme 1, 2, 3, and 4 to represent Eqs. \[44], \[68], \[69], and \[70], respectively. In the RG schemes 2, 3, and 4, the fermion self-energy can still be written as Eq. \[45], with the expressions of $C_{1,2,3}$ being given in Appendix C. Numerical calculations show that the values of $C_{1,2,3}$ computed using RG schemes 2, 3, and 4 are precisely the same as those given by Eqs. \[46]-\[48]. Thus, these four different RG schemes lead to exactly the same results.

C. Interplay of Yukawa coupling and Coulomb interaction

At semimetal-insulator QCP, semi-Dirac fermions not only couple to the quantum fluctuation of excitonic order parameter $\phi$, but interact with each other through the Coulomb interaction. For completeness, it is necessary to consider both the Yukawa coupling and the Coulomb interaction and treat them equally. From the above analysis, we know that Yukawa coupling tends to drive parameter $a$ to decrease upon lowering the energy scale. In contrast, Coulomb interaction can increase $a$ in the low-energy regime. When both Yukawa coupling and Coulomb interaction are present, these two opposite tendencies might give rise to interesting low-energy behaviors of semi-Dirac fermions. This issue will be addressed in this subsection.

In a previous work, Isobe et al. studied the influence of Coulomb interaction on semi-Dirac fermions by utilizing the RG scheme Eq. \[70]. Because different RG schemes might give rise to unidentical results \[49, 50], we feel it helpful to revisit the effect of Coulomb interaction by employing the four RG schemes defined by Eq. \[44], and \[68], \[69], and \[70] respectively. Detailed analytic calculations lead us to

\[
\frac{dZ_f}{dl} = C'_1 Z_f, \tag{71}
\]

\[
\frac{da}{dl} = (C'_1 - C'_2) a, \tag{72}
\]

\[
\frac{dv}{dl} = (C'_1 - C'_3) v, \tag{73}
\]

\[
\frac{d\alpha}{dl} = (C'_3 - C'_1) \alpha. \tag{74}
\]

For RG schemes 1 and 4, $\beta$ is defined as $\beta = \frac{2\Lambda}{\alpha'}$, and the
FIG. 10: Flows of \(Z_f, a,\) and \(v\) considering long-range Coulomb interaction in semimetal phase in different RG schemes. The initial condition \(\alpha_0 = 1\) and \(\beta_0 = 1\) are taken.

The RG equation of \(\beta\) can be written as

\[
\frac{d\beta}{dl} = (2C'_3 - C'_1 - C'_2 - 1) \beta. \tag{75}
\]

For RG scheme 2, \(\beta\) is defined as \(\beta = \frac{a}{v}\), whose RG equation is

\[
\frac{d\beta}{dl} = \left( C'_3 - C'_2 - \frac{1}{2} \right) \beta. \tag{76}
\]

For RG scheme 3, \(\beta\) is defined as \(\beta = \frac{a}{v}\), and the corresponding RG equation is

\[
\frac{d\beta}{dl} = (C'_3 - C'_2 - 1) \beta. \tag{77}
\]

The expressions of \(C'_1, C'_2,\) and \(C'_3\) obtained by employing different RG schemes are given in Appendix D. The RG flows of \(Z_f, a,\) and \(v\) are shown in Fig. 10. According to Fig. 10(a), \(Z_f\) obtained by employing four RG schemes all flow to zero at large \(l\), thus normal FL description becomes invalid. The \(l\)-dependence of \(Z_f\) for RG scheme 1 is close to that for RG scheme 3 over a wide range of energies, but different from those obtained by means of RG schemes 2 and 4. Based on Fig. 10(b) and (c), it is easy to verify that

\[
\lim_{l \to \infty} \frac{\ln(1/Z_f)}{l} \to 0, \tag{78}
\]

but that

\[
\lim_{l \to \infty} \frac{\ln(1/Z_f)}{\ln(l)} \to \text{constant}. \tag{79}
\]

We see from the above two expressions that Coulomb interaction gives rise to MFL like behaviors in the lowest energy limit. This result is qualitatively the same within four different RG schemes, and agrees with the conclusion reached in Ref. [34]. As can be seen from Fig. 10(d) and (e), both \(a\) and \(v\) increase with growing length scale \(l\). In particular, the numerical results for \(a\) are almost identical for RG schemes 1, 3, and 4, but quantitatively larger than the result obtained by RG scheme 2. The numerical results for \(v\) in for different RG schemes are all very close to each other.

We then incorporate both the Yukawa coupling and Coulomb interaction, and study their interplay by means of RG method combined with \(1/N\) expansion. We will not give the calculational detail here, but only list the final RG equations:

\[
\frac{dZ_f}{dl} = (C_1 + C'_1) Z_f, \tag{80}
\]

\[
\frac{da}{dl} = (C_1 + C'_1 - C_2 - C'_2) a, \tag{81}
\]

\[
\frac{dv}{dl} = (C'_1 - C'_3) v. \tag{82}
\]
FIG. 11: Flows of $Z_f$, $a$, and $v$ considering both of quantum fluctuation of insulating phase and long-range Coulomb interaction at QCP in RG scheme 1. The initial condition $\beta_0 = 1$ is taken.

\[
\frac{d\alpha}{dl} = (C_3' - C_1') \alpha. \tag{83}
\]

The RG equation of $\beta$ are found to be

\[
\frac{d\beta}{dl} = (C_3 - C_2 + 2C_3' - C_1' - C_2' - 1) \beta, \tag{84}
\]

for RG schemes 1 and 4,

\[
\frac{d\beta}{dl} = \left( C_3 + C_3' - C_2 - C_2' - \frac{1}{2} \right) \beta, \tag{85}
\]

for RG scheme 2, and

\[
\frac{d\beta}{dl} = (C_3 + C_3' - C_2 - C_2' - 1) \beta \tag{86}
\]

for RG scheme 3.

We present the low-energy behaviors of parameters $Z_f$, $a$, and $v$ in Fig. 11 by adopting RG scheme 1 as an example. As shown by Fig. 11(a), $Z_f$ flows monotonously to zero in the lowest energy limit. Using the results displayed in Fig. 11(b) and (c), we find that $Z_f$ manifests the following asymptotic behavior:

\[
\lim_{l \to \infty} \frac{\ln(1/Z_f)}{l} \to \text{constant}, \tag{87}
\]

and

\[
\lim_{l \to \infty} \frac{\ln(1/Z_f)}{\ln(l)} \to \infty. \tag{88}
\]

Obviously, the semi-Dirac fermions exhibit NFL behaviors at the semimetal-insulator QCP, so the schematic phase diagram depicted in Fig. 11 is still applicable. We observe from Fig. 11(d) that the parameter $a$ displays a non-monotonic dependence on the length scale $l$: as $l$ grows, $a$ first increases and then decreases. However, Fig. 11(e) shows that parameter $v$ increases monotonously with growing $l$. Since $v$ does not flow at all in case there is only Yukawa coupling, the low-energy behavior of $v$ is indeed determined by Coulomb interaction. The numerical results obtained by applying the RG schemes 2, 3, and 4, which are not presented here, are qualitatively the same as those obtained based on RG scheme 1.

VI. SUMMARY AND DISCUSSIONS

In summary, we have studied dynamical excitonic gap generation induced by long-range Coulomb interaction in a 2D semi-Dirac semimetal. The critical Coulomb interaction strength $\alpha_c$ has been calculated by solving the self-consistent DS equation of dynamical excitonic gap. By adopting three frequently used approximations, we have showed that a moderately strong Coulomb interaction suffices to generate a finite excitonic gap. It is therefore much easier for Coulomb interaction to trigger
excitonic pairing in a 2D semi-Dirac semimetal is smaller or at least very close to the critical value \( \alpha_c \) obtained in our DS equation analysis. It is certainly also possible to open an excitonic gap in other 2D semi-Dirac semimetal materials, which deserves a systematic investigation. We hope that experiments, including but not restricted to ARPES, would be performed in the future to search the predicted excitonic insulating state in various 2D semi-Dirac materials, with TiO\(_2\)/VO\(_2\) nanostructure being the most promising candidate.

We also have showed that 2D semi-Dirac fermions exhibit distinct behaviors in the massless semimetal phase, excitonic insulating phase, and at the semimetal-insulator QCP. Specifically, the massless semi-Dirac fermions couple strongly to the quantum fluctuation of excitonic order parameter by a Yukawa-type coupling at the QCP. We have examined the impact of this coupling on the low-energy properties of fermions by carrying out a detailed RG analysis, and revealed unusual NFL behaviors of massless fermions and other interesting quantum critical phenomena.

In our present DS equation studies, we have neglected a number of physical effects to simplify numerical computation, including the fermion velocity renormalization \([75, 70, 80]\), strong fermion damping \([70, 82, 83]\), and vertex corrections \([70, 83]\). These effects formally embodied in the functions \(A_{0,1,2}(\omega, k_x, k_y)\) appearing in Eq. \((11)\) and in the function \(\Gamma(\varepsilon, \mathbf{p}, \omega, \mathbf{k})\) appearing in Eq. \((13)\). To the leading order of \(1/N\) expansion, it is safe to set \(A_{0,1,2}(\omega, k_x, k_y) = \Gamma(\varepsilon, \mathbf{p}, \omega, \mathbf{k}) = 1\). However, because the physical flavor \(N\) is usually not large, the higher order corrections may be important. The impact of these corrections can be examined by solving the self-consistent equations of \(A_{0,1,2}(\omega, k_x, k_y)\) and \(m(\omega, k_x, k_y)\). In order not to spoil the Ward identity, the vertex corrections need to be properly included by introducing an appropriate ansatz \([79, 83, 120]\). The polarization function may also be self-consistently computed by using the full fermion propagator that contains \(A_{0,1,2}\) and \(m\) \([82, 129]\). While it is formally straightforward to write down the full set of self-consistent equations, it is highly nontrivial to solve them with high precision. The renormalized functions \(A_{0,1,2}(\omega, k_x, k_y)\) and the dynamically generated gap \(m(\omega, k_x, k_y)\) depend on energy and two components of momenta separately, as a consequence of explicit Lorentz symmetry breaking and strong anisotropy in fermion dispersion. This makes it technically much harder to solve the coupled integral equations of \(A_{0,1,2}\) and \(m\).

To estimate the importance of higher order corrections, we now compare with the cases of QED\(_3\) and 2D Dirac semimetal. In the case QED\(_3\), the critical flavor for dynamical fermion mass generation is \(N_c \approx 3.24\) at the leading order of \(1/N\) expansion \([123]\) and becomes \(N_c \approx 4.0\) after including higher order corrections \([124]\). In 2D Dirac semimetal, we present in Table II the values of \(\alpha_c\) computed previously under three different approximations at the leading order of \(1/N\) expansion \([65, 70, 73, 74]\) and those obtained in the presence of higher order corrections \([79, 82, 83]\). For convenience, the values of \(\alpha_c\) obtained in our current work are also listed in Table II. According to the research experience accumulated in these studies, we find that higher order corrections do lead to quantitative change of the critical condition for dynamical gap generation. However, the analysis performed with truncation to the lowest order is still scientifically significant for two reasons. Firstly, it suffices to capture many important qualitative properties of dynamical gap generation, which are not changed by higher order corrections. Moreover, even the quantitative result, such as the critical parameter \(\alpha_c\), obtained at the lowest order truncation is usually only moderately altered by higher order corrections. In the case of QED\(_3\), \(N_c\) increases by only about one fourth due to non-leading order corrections. In a 2D Dirac semimetal, \(\alpha_c\) obtained in the instantaneous approximation increases by about one third comparing to the value obtained in the presence of higher order corrections. The value \(\alpha_c\) evaluated in GGG approximation is much smaller than the ones evaluated by using other approximations, but it still gives us a lower bound for the real critical point \(\alpha_c\). Therefore, although the critical value of \(\alpha_c\) obtained

|                | Lowest order truncation | Higher order corrections |
|----------------|-------------------------|--------------------------|
|                | Instan. | Khv. | GGG | \(\alpha_c \approx 2.33\) | \(\alpha_c \approx 1.13\) | \(\alpha_c \approx 0.92\) | \(3.2 < \alpha_c < 3.3\) | \(\alpha_c \approx 3.1\) | \(\alpha_{c,\text{min}} \approx 2.889\) | \(\alpha_{c,\text{max}} \approx 3.19\) | \(\alpha_c \approx 0.6\) | \(\alpha_c \approx 0.3 \sim 0.4\) | \(\alpha_c < 0.2\) | \(\text{in progress}\) |
| Dirac SM       | \[65, 70]\ | \[73]\ | \[74]\ | \[79]\ | \[82]\ | \[83]\ |
| semi-Dirac SM  | \(\alpha_c \approx 0.6\) | \(\alpha_c \approx 0.3 \sim 0.4\) | \(\alpha_c < 0.2\) | \(\text{in progress}\) |
we further write the polarization as 2D semi-Dirac semimetal to fall in the range 0.7 $\sim$ 1.0. In view of the quantitative difference between the values of $\alpha_c$ obtained under different approximations in the case 2D Dirac semimetal, as presented in Table A1, we would naively expect the critical parameter $\alpha_c$ for 2D semi-Dirac semimetal to fall in the range 0.7 $\sim$ 1.0 when higher order corrections are considered. Getting a precise value of $\alpha_c$ requires a more elaborative numerical computation of the coupled DS equations, which is now in progress and will be reported later. Moreover, in order to realize interaction-induced excitonic insulator, one could design certain new 2D semi-Dirac semimetal materials and endeavor to make the physical value of $\alpha$ as large as possible. Our theoretic analysis presented in this paper provides a helpful guide for such an interesting exploration.

Apart from the DS equation approach, one can study dynamical excitation gap generation by employing other powerful tools, such as RG approach [43, 47, 87, 143–146] and Monte Carlo simulation [90–97]. To examine whether a dynamical gap is opened, one could consider all possible four-fermion couplings, allowed by the lattice symmetry, and study their interplay with the Coulomb interaction. In the absence of Coulomb interaction, weak four-fermion couplings are usually irrelevant perturbations to the system. However, some of these couplings might be driven by the Coulomb interaction to become relevant under certain conditions. In that case, even an infinitely weak coupling flows to the strong coupling regime at low energies, leading to the excitonic pairing instability of the system. This is an efficient way to study dynamical gap generation and has wide applications in QED, 3D quadratic semimetal [143, 146] and 3D Dirac/Weyl semimetal [149], 3D nodal line semimetal [150, 151], and 3D double/triple-Weyl semimetal [152]. A comprehensive RG analysis of the role played by short-range interactions in 2D semi-Dirac semimetal is still lacking. We are now working on this problem and would present the work in a separate paper.

**Appendix A: Calculation of polarization $\Pi_{33}$**

We now compute the polarization for the coupling between semi-Dirac fermions $\psi$ and quantum fluctuation of insulating order parameter $\phi$, which is defined as

$$
\Pi_{33}(\Omega, q) = N \int \frac{d\omega}{2\pi} \int \frac{d^2k}{(2\pi)^2} \text{Tr} \left[ \tau_3 G_0(\omega, k) \tau_3 G_0(\omega + \Omega, k + q) \right].
$$

Substituting the fermion propagator Eq. (4) into Eq. (A1), we obtain

$$
\Pi_{33}(\Omega, q_x, q_y) = -2N \int \frac{d\omega}{2\pi} \int \frac{d^2k}{(2\pi)^2} \frac{\omega (\omega + \Omega) + a^2 k_x^2 (k_x + q_x)^2 + v^2 k_y (k_y + q_y)}{[\omega^2 + a^2 k_x^2 + v^2 k_y^2] \left( \omega^2 + a^2 (k_x + q_x)^2 + v (k_y + q_y)^2 \right)}.
$$

Using the Feynman parameterization

$$
\frac{1}{AB} = \int_0^1 dx \frac{1}{[xA + (1-x)B]^2},
$$

we further write the polarization as

$$
\Pi_{33}(\Omega, q_x, q_y) = -2N \int_0^1 dx \int \frac{dk_x}{2\pi} \int \frac{dk_y}{2\pi} \int \frac{d\omega}{2\pi} \int \frac{d\omega}{2\pi} \times \left\{ \frac{\omega^2 + k_y^2 + x(1-x) \left( \omega^2 + q_y^2 \right)}{[\omega^2 + k_y^2 + x(1-x) \left( \omega^2 + q_y^2 \right) + k_x^2 (k_x + q_x)^2]^2 - \frac{1}{\omega^2 + k_y^2 + k_x^2}} \right\},
$$
where we have made the re-scaling manipulations:
\[ q_x \rightarrow \frac{q_x}{\sqrt{a}}, \quad k_x \rightarrow \frac{k_x}{\sqrt{a}}, \quad q_y \rightarrow \frac{q_y}{v}, \quad k_y \rightarrow \frac{k_y}{v}. \] (A5)

Moreover, we have used \( \Pi_{33}(\Omega, \frac{q_x}{\sqrt{a}}, \frac{q_y}{v}) - \Pi_{33}(0, 0, 0) \) to regularize the polarization function. We then define a new variable \( K = (\omega, k_y) \) and carry out the integration over \( K \), which yields
\[
\Pi_{33}(\Omega, \frac{q_x}{\sqrt{a}}, \frac{q_y}{v}) = -\frac{N}{2\pi \sqrt{av}} \int \frac{dk_x}{2\pi} \int_0^1 dx \left[ \frac{x (\Omega^2 + q_y^2)}{\Lambda^2 + x(1-x) (\Omega^2 + q_y^2) + k_x^4} - \frac{x (\Omega^2 + q_y^2)}{x(1-x) (\Omega^2 + q_y^2) + k_x^4} \right] \left( \frac{\Lambda + k_x^2}{k_x^2} \right)^{\frac{1}{2}}. \] (A6)

After integrating over \( k_x \) and retaining the leading term, we get
\[
\Pi_{33}(\Omega, 0, \frac{q_y}{v}) = \frac{3N (\Omega^2 + q_y^2)^{\frac{1}{2}}}{2\sqrt{2\pi \sqrt{av}}} \int_0^1 dx [x(1-x)]^{\frac{1}{2}} = c_1 \frac{N}{\sqrt{av}} (\Omega^2 + q_y^2)^{\frac{1}{2}}, \] (A8)

where \( c_1 = \frac{\Gamma(\frac{1}{2})}{\sqrt{\pi}} \approx 0.208657 \).

1. \( q_x = 0 \)

In the limit \( q_x = 0 \), we have
\[
\Pi_{33}(\Omega, 0, \frac{q_y}{v}) = -\frac{N}{2\pi \sqrt{av}} \int \frac{dk_x}{2\pi} \int_0^1 dx \left[ \frac{x (\Omega^2 + q_y^2)}{\Lambda^2 + x(1-x) (\Omega^2 + q_y^2) + k_x^4} - \frac{x (\Omega^2 + q_y^2)}{x(1-x) (\Omega^2 + q_y^2) + k_x^4} \right]. \] (A7)

In the case \( \Omega = 0 \) and \( q_y = 0 \), the polarization is given by
\[
\Pi_{33}(0, \frac{q_x}{\sqrt{a}}, 0) = -\frac{N}{\pi \sqrt{av}} \left[ \frac{1}{2} \ln \left( \frac{\Lambda^2 + (k_x + q_x)^4}{(k_x + q_x)^4} \right) + \frac{1}{2} \int_0^1 dx \left[ \frac{k_x^4 - k_x^2 (k_x + q_x)^2}{\Lambda^2 + x(1-x) (\Omega^2 + q_y^2) + k_x^4} \right] - \frac{1}{2} \ln \left( \frac{\Lambda^2 + k_x^4}{k_x^4} \right) \right] \). (A9)

Integrating over \( x \) and retaining the leading term gives rise to
\[
\Pi_{33}(0, \frac{q_x}{\sqrt{a}}, 0) = \frac{N}{4\pi^2 \sqrt{av}} \int_{-\infty}^{+\infty} dk_x \left( \frac{q_x + k_x + q_x)^4 - k_x^2 (k_x + q_x)^2}{(k_x + q_x)^4 - k_x^4} \right) \ln \left( \frac{(k_x + q_x)^4}{k_x^4} \right). \] (A10)

We then assume \( k_x = |q_x| y \), valid for both positive and negative \( q_x \), and convert \( \Pi_{33} \) to
\[
\Pi_{33}(0, \frac{q_x}{\sqrt{a}}, 0) = \frac{N}{4\pi^2} \left\{ \int_0^1 dy \frac{y^2}{y^2 + (y - 1)^2} \ln \left( \frac{y^4}{(y - 1)^4} \right) + \int_0^\infty dy \frac{2y + 1}{(y + 1)^2 + y^2} \ln \left( \frac{(y + 1)^4}{y^4} \right) \right\} |q_x| \sqrt{av}, \] (A11)

which leads
\[
\Pi_{33}(0, \frac{q_x}{\sqrt{a}}, 0) = c_2 \frac{N}{\sqrt{av}} |q_x|, \] (A12)

where \( c_2 = \frac{1}{4} \).
3. $q_y = 0$ and $\Omega \gg a q_z^2$

In the limit $q_y = 0$, we can expand the polarization in powers of $\frac{a q_z^2}{\Omega}$ and retain the leading and sub-leading terms, which simplifies $\Pi_{33}$ to the following form

$$
\Pi_{33}(\Omega, q_x, 0) = c_1 \frac{N}{\sqrt{av}} \Omega^{\frac{1}{2}} + \frac{1}{4 \pi^2} \frac{N}{\sqrt{av}} \frac{q_x^2}{\Omega^{\frac{1}{2}}} I_1, \quad \text{(A13)}
$$

where

$$
I_1 = \int_{-\infty}^{+\infty} dy \int_0^1 dx \left[ -\frac{y^2}{[x(1-x) + y^2]} + \frac{-6 x^2 y^2 + 8 x y^6}{[x(1-x) + y^2]^2} + \frac{16 x^3 y^6}{[x(1-x) + y^2]^3} \right] = \frac{5\pi^\frac{3}{2} \Gamma(\frac{3}{4})}{32 \sqrt{\pi} \Gamma(\frac{3}{2})}. \quad \text{(A14)}
$$

Now $\Pi_{33}$ can be approximately written as

$$
\Pi_{33}(\Omega, q_x, 0) \approx c_1 \frac{N}{\sqrt{av}} \Omega^{\frac{1}{2}} + c_2 \frac{N}{\sqrt{av}} \frac{q_x^2}{\Omega^{\frac{1}{2}}} \approx c_1 \frac{N}{\sqrt{av}} \Omega^{\frac{1}{2}}, \quad \text{(A15)}
$$

where $c_3 = \frac{5\pi^\frac{3}{2} \Gamma(\frac{3}{4})}{32 \sqrt{\pi} \Gamma(\frac{3}{2})}$.

4. Ansatz for $\Pi_{33}$

According to the polarization calculated in different limits, as shown in Eqs. (A8), (A12), and (A15), we find it appropriate to express $\Pi_{33}$ by the following ansatz:

$$
\Pi_{33}(\Omega, q_x, q_y) = \frac{N}{\sqrt{av}} [b_1 (\Omega^2 + q_x^2) + b_2 q_x^4]^{\frac{1}{4}}, \quad \text{(A16)}
$$

where $b_1 = c_1^4$ and $b_2 = c_2^4$. Using the re-scaling relations $\frac{q_x}{\sqrt{\pi}} \rightarrow q_x$ and $\frac{q_y}{v} \rightarrow q_y$, we eventually write $\Pi_{33}$ in the form

$$
\Pi_{33}(\Omega, q_x, q_y) = \frac{N}{\sqrt{av}} [b_1 (\Omega^2 + v^2 q_y^2) + b_2 a^2 q_y^4]^{\frac{1}{4}}. \quad \text{(A17)}
$$

Appendix B: Self-Energy of Semi-Dirac fermion

The self-energy of semi-Dirac fermion induced by the quantum fluctuation of excitonic insulating order parameter is defined as

$$
\Sigma_{fb}(\omega, k) = \int \frac{d\Omega}{2\pi} \frac{d^2 q}{(2\pi)^2} \tau_3 G_0(\omega + \Omega, k + q) \tau_3 D(\Omega, q) \quad \text{(B1)}
$$

to the leading order of perturbative expansion, where

$$
D(\Omega, q) = \frac{1}{\Pi_{33}(\Omega, q)}. \quad \text{(B2)}
$$

Substituting Eq. (4) into Eq. (B1), we obtain

$$
\Sigma_{fb}(\omega, k) = \int' \frac{d\Omega}{2\pi} \frac{d^2 q}{(2\pi)^2} i (\omega + \Omega) - a (k_x + q_x)^2 \tau_1 - v (k_y + q_y) \tau_2 D(\Omega, q). \quad \text{(B3)}
$$

It is easy to verify that

$$
\Sigma_{fb}(0, 0) = - \int' \frac{d\Omega}{2\pi} \frac{d^2 q}{(2\pi)^2} \frac{aq_x^2 \tau_1}{\Omega^2 + a^2 q_x^2 + v^2 q_y^2} D(\Omega, q). \quad \text{(B4)}
$$
where is not divergent in the lowest energy limit. This constant contribution plays no role in the low-energy region, and thus can be safely dropped in the RG analysis. Expanding $\Sigma_f(\omega, k)$ in powers of small values of $i\omega, k_x,$ and $k_y,$ and retaining the leading term, we find that

$$\Sigma_f(\omega, k) \approx (-i\omega)\Sigma_1 + ak_x^2\Sigma_2 + v k_y \Sigma_3,$$

(B5)

where

$$\Sigma_1 = \int \frac{d\Omega}{2\pi} \frac{d^2 q}{(2\pi)^2} \frac{\Omega^2 - a^2 q_x^4 - v^2 q_y^2}{(\Omega^2 + a^2 q_x^4 + v^2 q_y^2)^3} D(\Omega, q),$$

(B6)

$$\Sigma_2 = \int \frac{d\Omega}{2\pi} \frac{d^2 q}{(2\pi)^2} \frac{-\Omega^4 - 3a^4 q_x^4 + 12a^2 q_x^4 q_y^2 + 12a^2 q_x^4 v^2 q_y^2 - 2\Omega^2 v^2 q_y^2 - v^4 q_y^4}{(\Omega^2 + a^2 q_x^4 + v^2 q_y^2)^3} D(\Omega, q),$$

(B7)

$$\Sigma_3 = \int \frac{d\Omega}{2\pi} \frac{d^2 q}{(2\pi)^2} \frac{-\Omega^4 - a^2 q_x^4 + v^2 q_y^2}{(\Omega^2 + a^2 q_x^4 + v^2 q_y^2)^3} D(\Omega, q).$$

(B8)

We now need to perform RG re-scaling manipulations. Firstly, we adopt a RG scheme which integrates over $\Omega$ and momenta in the following way:

$$-\infty < \Omega < \infty, \quad b \Lambda < E_q < \Lambda, \quad \text{with} \quad E_q = \sqrt{a^2 q_x^4 + v^2 q_y^2},$$

(B9)

where $b = e^{-t}.$ If we define

$$E_q = \sqrt{a^2 q_x^4 + v^2 q_y^2}, \quad \delta = \frac{aq_x^2}{v|q_y|},$$

(B10)

the two components of momenta are given by

$$|q_x| = \frac{\sqrt{\delta} \sqrt{E_q}}{\sqrt{a} (1 + \delta^2)^{\frac{1}{2}}}, \quad |q_y| = \frac{E_q}{v\sqrt{1 + \delta^2}}.$$  

(B11)

Therefore, the integration over $q_x$ and $q_y$ can be converted to the integration of over $E_q$ and $\delta,$ through the relation:

$$d|q_x|d|q_y| = \left| \frac{\partial |q_x|}{\partial E_q} \frac{\partial |q_y|}{\partial \delta} - \frac{\partial |q_x|}{\partial \delta} \frac{\partial |q_y|}{\partial E_q} \right| dE_q d\delta$$

$$= \frac{\sqrt{E_q}}{2v\sqrt{a}\sqrt{\delta} (1 + \delta^2)^{\frac{1}{2}}} dE_q d\delta.$$  

(B12)

We now can calculate Eqs. (B6), (B8) by using the transformations given by Eq. (B11) and Eq. (B12) along with the RG scheme (B9), and obtain

$$\Sigma_1 = C_1 \ln(b^{-1}), \quad \Sigma_2 = C_2 \ln(b^{-1}), \quad \Sigma_3 = C_3 \ln(b^{-1}),$$

(B13)

where

$$C_1 = \frac{1}{4N\pi^4} \int_{-\infty}^{+\infty} dx \int_0^{+\infty} d\delta \frac{1}{\delta^{\frac{1}{2}} (1 + \delta^2)^{\frac{1}{2}}} \frac{x^2 - 1}{(x^2 + 1)^2} G(x, \delta),$$

(B14)

$$C_2 = \frac{1}{4N\pi^4} \int_{-\infty}^{+\infty} dx \int_0^{+\infty} d\delta \frac{1}{\delta^{\frac{1}{2}} (1 + \delta^2)^{\frac{1}{2}}}$$

$$\times \frac{-x^4 (1 + \delta^2)^2 - 3\delta^4 + 12x^2 \delta^2 (1 + \delta^2) + 12\delta^2 - 2x^2 (1 + \delta^2) - 1}{(x^2 + 1)^2} G(x, \delta),$$

(B15)

$$C_3 = \frac{1}{4N\pi^4} \int_{-\infty}^{+\infty} dx \int_0^{+\infty} d\delta \frac{1}{\delta^{\frac{1}{2}} (1 + \delta^2)^{\frac{1}{2}}} \frac{-x^2 (1 + \delta^2) - \delta^2 + 1}{(x^2 + 1)^2} G(x, \delta),$$

(B16)

$$G^{-1} = \left[ b_1 x^2 (1 + \delta^2) + b_2 \delta^2 + b_1 \right]^{\frac{1}{2}}.$$  

(B17)
Appendix C: Calculation of $C_{1,2,3}$ using different RG schemes

As discussed in Sec. [VIII], there are a number of different RG schemes, which are distinguished by the different manners to integrate over energy and momenta. Here, we provide the expressions for $C_{1,2,3}$ obtained separately by employing these RG schemes.

For the RG scheme

$$
\int^{+\infty}_{+\infty} d\Omega d^2 q = \int^{+\infty}_{-\infty} d\Omega \left( \int^{+\Lambda}_{-\Lambda} dq_x \int^{+\Lambda}_{-\Lambda} dq_y \right),
$$

(C1)

the expressions of $C_i$ with $(i = 1, 2, 3)$ are given by

$$
C_1 = \frac{1}{8N\pi^3} \int^{+\infty}_{-\infty} dx \int^{+\infty}_{-\infty} dy \frac{x^2 - y^2 - 1}{(x^2 + y^2)^2} G(x, y),
$$

(C2)

$$
C_2 = \frac{1}{8N\pi^3} \int^{+\infty}_{-\infty} dx \int^{+\infty}_{-\infty} dy \frac{-x^4 - 3 + 12x^2 + 12y^2 - 2x^2y^2 - y^4}{(x^2 + y^2)^3} G(x, y),
$$

(C3)

$$
C_3 = \frac{1}{8N\pi^3} \int^{+\infty}_{-\infty} dx \int^{+\infty}_{-\infty} dy \frac{-x^2 - 1 + y^2}{(x^2 + y^2)^3} G(x, y),
$$

(C4)

$$
G^{-1} = \left[ b_1 (x^2 + y^2) + b_2 \right]^\frac{3}{4}.
$$

(C5)

By virtue of the exchange symmetry between variables $x$ and $y$, it is easy to find that

$$
C_1 = C_3 = \frac{1}{4N\pi^3} \int^{+\infty}_{-\infty} dx \int^{+\infty}_{-\infty} dy \frac{-1}{(x^2 + y^2)^2} \frac{1}{[b_1 (x^2 + y^2) + b_2]^\frac{3}{4}}.
$$

(C6)

For the RG scheme given by

$$
\int^{+\infty}_{-\infty} d\Omega d^2 q = \int^{+\infty}_{-\infty} d\Omega \int^{+\infty}_{-\infty} dq_x \left( \int^{+\Lambda}_{-\Lambda} + \int^{+\Lambda}_{-\Lambda} \right) dq_y,
$$

(C7)

we accordingly find that

$$
C_1 = \frac{1}{4N\pi^3} \int^{+\infty}_{-\infty} dx \int^{+\infty}_{-\infty} dy \frac{x^2 - y^4 - 1}{(x^2 + y^4 + 1)^2} G(x, y),
$$

(C8)

$$
C_2 = \frac{1}{4N\pi^3} \int^{+\infty}_{-\infty} dx \int^{+\infty}_{-\infty} dy \frac{-x^4 - 3x^2 + 12x^2 + 12y^4 - 2x^2y^2 - y^4}{(x^2 + y^4 + 1)^3} \frac{1}{[b_1 (x^2 + 1) + b_2 y^4]^\frac{3}{4}} G(x, y),
$$

(C9)

$$
C_3 = \frac{1}{4N\pi^3} \int^{+\infty}_{-\infty} dx \int^{+\infty}_{-\infty} dy \frac{-x^2 - 1 + y^2}{(x^2 + y^4 + 1)^2} \frac{1}{[b_1 (x^2 + 1) + b_2 y^4]^\frac{3}{4}} G(x, y),
$$

(C10)

$$
G^{-1} = \left[ b_1 (x^2 + 1) + b_2 y^4 \right]^\frac{3}{4}.
$$

(C11)

For the RG scheme

$$
\int^{+\infty}_{-\infty} d\Omega d^2 q = \left( \int^{+\Lambda}_{-\Lambda} + \int^{+\Lambda}_{-\Lambda} \right) d\Omega \int^{+\infty}_{-\infty} dq_x \int^{+\infty}_{-\infty} dq_y,
$$

(C12)

we obtain

$$
C_1 = \frac{1}{4N\pi^3} \int^{+\infty}_{-\infty} dx \int^{+\infty}_{-\infty} dy \frac{-x^4 - y^4}{(1 + x^4 + y^4)^2} G(x, y),
$$

(C13)

$$
C_2 = \frac{1}{4N\pi^3} \int^{+\infty}_{-\infty} dx \int^{+\infty}_{-\infty} dy \frac{-3x^8 + 12x^4 + 12x^4 y^2 - 2y^2 - y^4}{(1 + x^4 + y^4)^3} G(x, y),
$$

(C14)

$$
C_3 = \frac{1}{4N\pi^3} \int^{+\infty}_{-\infty} dx \int^{+\infty}_{-\infty} dy \frac{-1 - x^4 + y^2}{(1 + x^4 + y^2)^2} G(x, y),
$$

(C15)

$$
G^{-1} = \left[ b_1 (1 + y^2) + b_2 x^4 \right]^\frac{3}{4}.
$$

(C16)
All the above expressions for $C_{1,2,3}$ are used in Sec. [4.3] to investigate the Yukawa-coupling between the semi-Dirac fermions and the quantum fluctuation of excitonic order parameter at the semimetal-insulator QCP. We find that these different RG schemes lead to essentially the same conclusion.

**Appendix D: Expressions of $C_{1,2,3}'$ in four different RG schemes**

In RG scheme 1 shown in Eq. (B39), $C_{1}'$ can be computed through $C_{1}$ given by Eq. (B14) by replacing $G(x, \delta)$ with $-\hat{G}'(x, \delta)$, and $C_{2,3}'$ can be computed through $C_{2,3}$ shown in Eqs. (B15) and (B16) by replacing $G(x, \delta)$ with $G'(x, \delta)$, where $\hat{G}'(x, \delta)$ is given by

$$G'^{-1}(x, \delta) = \sqrt{\frac{\delta + \frac{\beta}{(1+\beta^2)^{\frac{1}{2}}}}{2\pi N\alpha}} + \left[ \frac{d_x \delta}{(x^2 + c_0 \delta^2 + 1)^{\frac{1}{2}}} + \frac{d_y}{(x^2 + c_0 \delta^2 + 1)^{\frac{1}{2}}} \right], \quad (D1)$$

in which $\beta = \frac{a \Delta}{v_{\text{F}}}$.

In RG scheme 2 shown in Eq. (C1), $C_{1}'$ can be computed through $C_{1}$ given by Eq. (C2) by replacing $G(x, y)$ with $-\hat{G}'(x, y)$, and $C_{2,3}'$ can be computed through $C_{2,3}$ given by Eqs. (C3) and (C4) by replacing $G(x, y)$ with $G'(x, y)$, where $\hat{G}'(x, y)$ can be written as

$$G'^{-1}(x, y) = \sqrt{\frac{1 + \beta^2 y^2}{2\pi N\alpha}} + \left[ \frac{d_x x}{(x^2 + c_0 + y^2)^{\frac{1}{2}}} + \frac{d_y y^2}{(x^2 + c_0 + y^2)^{\frac{1}{2}}} \right], \quad (D2)$$

in which $\beta = \frac{a \Delta}{v_{\text{F}}}$.

In RG scheme 3 shown in Eq. (C7), $C_{1}'$ can be computed through $C_{1}$ given by Eq. (C8) by replacing $G(x, y)$ with $-\hat{G}'(x, y)$, and $C_{2,3}'$ can be computed through $C_{2,3}$ given by Eqs. (C9) and (C10) by replacing $G(x, y)$ with $G'(x, y)$, where $\hat{G}'(x, y)$ takes the form

$$G'^{-1}(x, y) = \sqrt{\frac{y^2 + \beta}{2\pi N\alpha}} + \left[ \frac{d_x y^2}{(x^2 + c_0 y^4 + 1)^{\frac{1}{2}}} + \frac{d_y}{(x^2 + c_0 y^4 + 1)^{\frac{1}{2}}} \right], \quad (D3)$$

in which $\beta = \frac{a \Delta}{v_{\text{F}}}$.

In RG scheme 4 shown in Eq. (C12), $C_{1}'$ can be computed through $C_{1}$ shown in Eq. (C13) by replacing $G(x, y)$ with $-\hat{G}'(x, y)$, and $C_{2,3}$ can be computed through $C_{2,3}$ given by Eqs. (C14) and (C15) by replacing $G(x, y)$ with $G'(x, y)$, where $\hat{G}'(x, y)$ has the expression

$$G'^{-1}(x, y) = \sqrt{\frac{x^2 + \beta y^2}{2\pi N\alpha}} + \left[ \frac{d_x x^2}{(1 + c_0 x^4 + y^2)^{\frac{1}{2}}} + \frac{d_y}{(1 + c_0 x^4 + y^2)^{3/4}} \right], \quad (D4)$$

in which $\beta = \frac{a \Delta}{v_{\text{F}}}$.
