Abstract

**Background:** Colorectal cancer (CRC) is the third most common cancer prevalent in men, and the second in women worldwide. The exact cause and pathogenesis of this disease remains unknown. In every cell multiple phospholipase A\textsubscript{2} (PLA\textsubscript{2}) exists, but their contribution to the cell function has yet not been determined. The increased activity of these isoforms may be important in the generation of inflammatory mediators which finally are involved in the initiation of carcinogenesis. This study has explored the pathways involved in the differential response of HCT-15 and HT-29 colon cell lines during benzo(α)pyrene [B(α)P]-induced molecular changes.

**Methods:** HT-29 and HCT-15 cells were used for the present study. Benzo(α)pyrene [B(α)P]-induced molecular changes were evaluated through cell viability using MTT assay, reactive oxygen species (ROS) measurement using 2,7 dichloro-dihydro-fluorescin diacetate (DCFH-DA), The gene expressions of PLA\textsubscript{2} isoforms were estimated by RT-PCR. Further, knockdown of PLA\textsubscript{2} isoform in transfected cells was done with siRNA.

**Results:** The cell viability decreased significantly after exposure with B(α)P in both cell lines. Reactive oxygen species (ROS) production after exposure with B(α)P was significantly induced in both types of colon cell lines. The gene expressions of PLA\textsubscript{2} isoforms were also estimated. Three PLA\textsubscript{2} isoforms such as IB and, IID, IVA were induced after exposure with B(α)P respectively in HT -29 and HCT-15 cell lines. Further, a significant knockdown of PLA\textsubscript{2} isoform in transfected cells with siRNA, and B(α)P exposure was observed in HCT-15 and HT-29 cells. There was a significant induction of ROS in IVA transfected HCT-15 cells exposure with B(α)P.

**Conclusion:** It is concluded that each cell line behaved differently, specific PLA\textsubscript{2} siRNA are involved in controlling the cascades related ROS, depending upon the origin of the cells. Secretary phospholipase A\textsubscript{2} (sPLA\textsubscript{2}) inhibitors are likely to have a therapeutic potential in colon pathologies.

**Introduction**
Colorectal cancer (CRC) is the third most common cancer in men and the second in women worldwide [1]. The incidence of CRC has been reported to increase 2-4 times in the past few decades in many countries of the Asia-Pacific region. Presently the most common treatment option is surgery, and that
also depends on various factors like the site of the cancer and the presence and extent of metastasis. The risk of colorectal cancer begins with the formation of abnormal polyp growth that later grows to cancer. The major causes include the over-eating, alcohol consumption and smoking. Studies also suggest that a proper life-style maintenance including the controlled diet could reduce the abnormal poly formation and further cancer. Ursolic acid is a phytochemical present in most plants and has the ability to reduce the cell proliferation of breast and colon cancer cells through various pathways [2]. The Benzo(α)pyrene [B(α)P], a known carcinogen, presents in diet and environment such as cigarette smoke (CS), grilled meats and byproducts of industrial incineration [3]. The oxidative stress caused by the constituents of CS such as B(α)P in normal as well as in the mutated cells may lead to the remodeling of membrane lipids through upregulation of various signaling events such as activation of lipid specific enzymes especially phospholipases. Almost in every cell type, multiple isoforms of phospholipase A₂ (PLA₂) but their contribution to the cell functions has not yet been clearly determined.

Phospholipase A₂ superfamily is composed of many lipolytic enzymes whose common feature is to hydrolyze the fatty acid present in the sn-2 position of glycerophospholipids. It is reported that PLA₂ can act synergistically with reactive oxygen species (ROS) to cause cellular injury due to enhanced susceptibility of peroxidized membrane to the action of PLA₂. Phospholipases type A₂ is involved in the generation of a wide range of biomediators, including lysosphospholipids, arachidonic acid, and metabolites of arachidonic acid that can enhance tumor cell growth, invasion, and metastasis [4]. However, it is not known whether PLA₂ isoforms are expressed in human colon cancer and whether PLA₂ isoforms influence the malignant potential of colon cancer cells. Besides that, PLA₂ isoenzymes may behave differentially to cigarette smoke condensate (CSC) and B(α)P (a major carcinogen of cigarette smoke) in vitro.

This study aims to explore the pathways involved in the differential response of HCT-15 and HT-29 colon cell lines during [B(α)P]-induced molecular changes.

Methods

Cell lines:
Colon adenocarcinoma cancer cell lines (HCT-15 and HT-29) were procured from National Centre for Cell Science, Pune, India.

[β(α)p] Preparation:
B(α)P were procured from sigma USA and dissolved in DMSO, the working concentration (0.025%) was prepared in a sterile medium.

Cell Culture:
HCT-15 and HT-29 were maintained in continuous culture at 37 °C and 5% CO₂ in RPMI-1640 and DMEM medium supplemented with 10% fetal bovine serum (FBS), 2 mM L-glutamine, 100 units/ml penicillin, 100 µg/ml streptomycin and 0.5 µg/ml fungizone respectively.

Cell Viability Assay:
Effect of B(α)P on cell viability was evaluated by the 3-(4, 5- dimethylthiazol-2-yl)-diphenyltetrazolium bromide (MTT) dye uptake method described previously [5]. Briefly, 2 x 10³ cells were seeded in 96-well plates, and treated with varying concentrations of B(α)P for 24 hr, 48 hr, and 72 hr. After the desired incubation time, 20 µl of MTT solution (2.5 mg/ml) was added to each well. After 4 hr, resultant formazan crystals were dissolved in 40 µl of lysis buffer (20% SDS dissolved in 50% each of DMF and ddH₂O). The developed colour was read at 570 nm on ELISA reader.

Ros And Superoxide Radicals (sor):
Levels of intracellular ROS, mitochondrial ROS and SOR were measured by the shift in fluorescent intensity resulting from oxidation of DCFH-DA (for ROS), DHR123 (for Mitochondrial ROS) and DHE (for Superoxide radical) fluorescence dye [6]. Briefly, 0.5 x 10⁵ cells/well were seeded into 12-well plates and allowed to grow overnight in complete media. After 24 hr of incubation, the medium was replaced with a fresh medium and the cells were treated with varying concentrations of B(α)P for a specific time interval. Cells were incubated with 5 µM DCFH-DA, 10 µM DHR123 or 10 µM DHE fluorescence dye for 30 min. Cells were challenged with B(α)P for 24 hr and 48 hr. Thereafter, cells were washed, harvested and resuspended in chilled phosphate buffer saline (PBS). Finally, cells were subjected to fluorescence-activated cell sorting (FACS; Beckton Dickinson FACSCan). Levels of ROS and SOR were represented in terms of mean fluorescent intensity (MFI).

Rna Extraction And Cdna Synthesis:
Total RNA was isolated by using Trizol reagent according to the manufacturer’s instructions. Briefly, 1 ml Trizol reagent was added to the cells followed by chloroform. The mixture was incubated at room temperature for 15 min and centrifuged at 12000 x g for 15 min at 4°C resulting in the separation of an upper aqueous phase and lower organic phase. The upper aqueous phase was carefully transferred to a fresh eppendorf tube. After adding and shaking with isopropanol mixture was incubated for 10 min and then centrifuged at 12000 x g for 10 min. The pellet thus obtained was washed with 75% ethanol followed by centrifugation for 5 min at 7,500 x g. The RNA pellet was air-dried and dissolved in an appropriate volume of DEPC water and stored at -80°C. Spectrophotometric measurement of RNA was done to quantify its purity. Further, one microgram RNA was used for cDNA synthesis. The cDNA synthesis was carried out from the purified and intact total RNA by using the Revert AidTM first strand cDNA synthesis kit (Fementas) according to the manufacturer’s instructions.

Reverse Transcription-polymerase Chain Reaction (rt-pcr):
Effect of B(α)P on mRNA expression of PLA2 isoforms was conducted through RT-PCR for the analysis of mRNA levels of PLA2 groups (IB, IID, III, IVA, IVB, IVC, VI, X, acid iPLA2, iPLA2). In RT-PCR reactions (25 µl) 100 ng cDNA was used as template DNA. The primer sequences were designed from the mRNA sequence of genes available in the Genebank or from previously published literature. The details of primer sequences and RT-PCR conditions used for the study are given in Table 1. The expression levels of different genes were calculated by relative quantification using b-actin transcript levels for normalization. The fold change in mRNA expressions was calculated by the comparative ΔΔCt method [7].
| S.No. | Name       | Primer Sequence | Product Size (bp) |
|-------|------------|-----------------|------------------|
| 1     | PLA<sub>2</sub>-IB | 5'-CTCAGGCAACCCCCGTGGATG-3' [a], 5'-GCGTTCGGCAGTGGCA-3' | 207              |
| 2     | PLA<sub>2</sub>-IID | 5'-CACCTGCTGGCCCCCTTGCT-3' [a], 5'-CAGGCAATGGCCTCCACCTGC-3' | 244              |

**Pla Gene Silencing:**

PLA<sub>2</sub> siRNA (IB, IID and IVA from Sigma Aldrich, USA) and scrambled siRNA were transfected into HCT-15 cells using transfection lipofectamine™ 2000 reagent as described previously [8]. The sequences of all siRNAs used in this study are provided in Table 2. Briefly, in HT-29 (IB) and HCT-15 (IID and IVA) cells the PLA<sub>2</sub> gene was silenced by using specific siRNA against the group IB, IID and IVA PLA<sub>2</sub> gene.
The cells (1 x 10^5 per well) were seeded in 2 ml antibiotic-free medium supplemented with 10% FBS in a six-well culture plate. After 60–80% confluency the cells were siRNA (IB, IID and IVA from Sigma Aldrich, USA) and scrambled siRNA were transfected into HCT-15 cells using transfection lipofectamine™ 2000 reagent. Briefly, in HT-29 (IB) and HCT-15 (IID and IVA) cells the PLA₂ gene was silenced by using specific siRNA against the group IB, IID and IVA PLA₂ gene. The cells (1 x 10^5 per well) were seeded in 2 ml antibiotic free medium supplemented with 10% FBS in a six well culture plate. After 60–80% confluency the cells were transfected with transfection reagents for 6–8 hr at 37°C in a CO₂ incubator following the recommended protocol provided with siRNA oligos. Before transfection, the medium was replaced with fresh medium without antibiotics. After transfection, additional media was added with 20% FBS so that the final concentration of FBS becomes 10% in the final mixture followed by the treatment with a specific concentration of B(α)P for 48 hr. After completion of the incubation time, total RNA was isolated as mentioned above transfected with transfection reagents for 6–8 hr at 37°C in a CO₂ incubator following the recommended protocol provided with siRNA oligos. Before transfection, the medium was replaced with fresh medium without antibiotics. After transfection, additional media was added with 20% FBS so that, the final concentration of FBS becomes 10% in the final mixture followed by the treatment with a specific concentration of B(α)P for 48 hr. After completion of the incubation time, total RNA was isolated as mentioned above. Similarly, one microgram of RNA was converted into cDNA and expression of group IB, IID and IVA PLA₂ was checked by qRT-PCR (Lightcycler 480, Roche diagnostics, Germany).
### Table 2: Sequences of siRNAs

| S. No. | Name of target gene | Sequence of siRNAs |
|--------|---------------------|-------------------|
| 1.     | PLA2 IIB            | Sense 5’ CCGGUACACCCACACCUAU (dT)(dT) 3’ Anti-sense 5’ AUAGGUGUGGGUGUACGGG (dT)(dT) 3’ |
| 2.     | PLA2 IID            | Sense 5’ ĈUUCUGACCUCUGAAGCU (dT)(dT) 3’ Anti-sense 5’ AGCUUCAGAAGGGUCAGAG (dT)(dT) 3’ |
| 3.     | PLA2 IVA            | Sense 5’ GACAUAAACCUGUGUGGGA (dT)(dT) 3’ Anti-sense 5’ UCCACACAGGGUUUAGGC (dT)(dT) 3’ |
| 4.     | Scrambled control   | Sense 5’ UUCUCGAACGUGUACCGU (dT)(dT) 3’ Anti-sense 5’ ACGUGACACGUUCGGAGAA (dT)(dT) 3’ |

**Statistical analysis:**

The data were analyzed using the SPSS 16.0 software. All results were expressed as mean ± SD. The differences in all data were assessed by one-way analysis of variance (ANOVA) by the Bonferroni test and nonparametric method such as Kurskali Wallice wherever required. The difference was taken as statistically significant at p < 0.05.

**Results**

**Effects of various concentrations of [B(α)P] on cell Viability:**

Figure 1 shows the effect of benzo(α)pyrene [B(α)P] on the viability of HCT-15 (Fig. 1A) and HT-29 cells (Fig. 1B). Significant cytotoxicity in HCT-15 cells was observed at 1.0 µM concentration of benzo(α)pyrene at 48 and 72 hr (p = 0.042). Whereas, at 24 hr it was evident only at 100 µM (p = 0.038). Cell survival at 1.0, 10, 50, 100, and 200 µM concentrations of B(α)P was found to be 88 ± 6.9%, 97 ± 5.5%, 92 ± 9.5%, 84 ± 3.1% and 58 ± 7.6% at 24 hr; 83 ± 3.6%, 80 ± 4.0%, 78 ± 1.5%, 73 ± 3.6% and 54 ± 1.7% at 48 hr; and 82 ± 4.0%, 79 ± 1.5%, 73 ± 2.6%, 59 ± 4.0% and 28 ± 2.1% at 72 hr respectively as compared to control in HCT-15 cells (Fig. 1A). Whereas, HT-29 cells were found to be in comparison to HCT-15 cells resistant to B(α)P as survival at 1.0, 10, 50, 100, and 200 µM concentration was found to be 96 ± 4.7%, 94 ± 7.7%, 89 ± 6.2%, 83 ± 7.3% and 67 ± 13.8% at 24 hr; 98 ± 6.4%, 85 ± 16.6%, 70 ± 8.5%, 47 ± 6.1% and 31 ± 8.5% at 48 hr; and 100 ± 6.9%, 84 ± 13.1%, 63 ± 14.4%, 39 ± 11.2% and 20 ± 2.6% at 72 hr respectively as compared to control (Fig. 1B).

**Intracellular Ros Production:**

Total ROS production in HCT-15 and HT-29 cells by B(α)P concentrations at different time intervals is
shown in Fig. 2. In HCT-15 cells, ROS production was found to be significantly increased 48 hr after treatment of cells with varying concentrations of B(α)P (0.1, 1.0, 10, 50, 100 and 200 µM) respectively as compared to control (100%) (p= 0.036) (Fig. 2A). In HT-29 cells, total ROS production was found to be 157 ± 39.1%, 254 ± 48.1%, 274 ± 18.3%, 444 ± 39.5%, 455 ± 46.0% and 279 ± 34.4% at 24 hr and, 214 ± 43.7%, 255 ± 29.8%, 255 ± 38.5%, 350 ± 37.2%, 300 ± 14.1%, and 232 ± 38.8% at 48 hr after treatment of cells at the above mentioned concentrations of B(α)P respectively as compared to control (100%) (p=0.042) (Fig. 2B).

Mitochondrial ROS levels after treatment with varying B(α)P concentrations (0 to 200 µM) in both the cell lines are shown in Fig. 3. In HCT-15 cells maximum the generation of ROS was observed at 50 µM concentration of B(α)P (221% vs 100% (control)). However, the generation of ROS declined almost to basal level after the treatment of cells at 200 µM (p = 0.028) (Fig. 3A). Whereas, ROS production in HT-29 cells was found to be at the peak after treatment with 1 µM concentration of B(α)P. However, the generation of ROS started declining after 10 µM and reached to basal level at 200 mM concentration (p = 0.032) (Fig. 3B).

The SOR production in HCT-15 cells after the exposure of various concentrations of B(α)P for 24 hr and 48 hr are shown in Fig. 4A. SOR production significantly decreased after the treatment of cells at 200 µM of B(α)P concentration as compared to the basal level(p = 0.022). We observed no change in the SOR production in HT-29 cells at 24 hr after treatment with B(α)P concentrations. However, at 48 hr SOR production was significantly increased after treatment with B(α)P at 1 µM to 50 µM concentration as compared to basal level (p = 0.034) (Fig. 4B).

**Pla Mrna Expression In Hct-15 And Ht-29 Cells:**
mRNA expressions of secretory phospholipase A2 (sPLA₂), cytosolic phospholipase A2 (cPLA₂) and independent phospholipase A2 (iPLA₂) groups were evaluated in the cells after challenging them with selected concentrations of B(α)P. PLA₂ gene expression at 24 hr and 48 hr of treatment with the B(α)P in HCT-15 and HT-29 are shown in Fig. 5A and 5B respectively. Group IVC PLA₂ was not detectable in HT-29 cells at the control level as well as after treatment with B(α)P concentrations. Whereas, it was
expressed in HCT-15 cells after treatment with B(α)P concentrations. The other groups, like PLA₂ IB of sPLA₂ family, was upregulated significantly from 0.62 ± 0.03 (control) to 0.92 ± 0.1, 1 ± 0.07, and 1.1 ± 0.15 after treatment with 0.01, 0.1, and 1.0 µM B(α)P concentrations respectively in HT-29 cells at 48 hr (p = 0.028)). While such effects were not observed in HCT-15 cells after treatment with B(α)P at 48 hr. However, the IID PLA₂ group was upregulated significantly. The relative gene expression after B(α)P treatment at 0.01, 0.1, and 1.0 µM B(α)P was upregulated significantly from 1.2 ± 0.07 (control) to 1.8 ± 0.21, 2 ± 0.13, and 2 ± 0.15 respectively in HCT-15 cells (p = 0.025). While such effects were not observed in HT-29 cells after treatment with B(α)P at 48 hr. The relative gene expression of PLA₂ group IVA was significantly upregulated after treatment with 0.01, 0.1, and 1.0 µM B(α)P from 0.9 ± 0.1 (control) to 1.4 ± 0.19, 1.8 ± 0.24, and 1.8 ± 0.27 respectively in HCT-15 cells at 48 hr (p = 0.041). All values are given in the form of a grey value of densitometry analysis by image J software. Levels of mRNA expression of III, IVB, IVC, VI, X, aiPLA₂ and iPLA₂ groups were not affected in the cells after treatment with B(α)P. (Fig. 5A and 5B).

Effect of silencing of IB, IID, and IVA PLA₂ by specific PLA2-siRNA in B(α)P treated colon cells:
The upregulation of IB, IID and IVA PLA₂ gene expression in the presence of B(α)P was inhibited by siRNA of IB, IID and IVA PLA₂ gene in HCT-15 and HT-29 colon cells.

Silencing of gene expression in HT-29 and HCT-15 cell lines by siRNA:
Relative gene expression (mean ± SD) of group IB at mRNA levels in siRNA (IB) without and with 0.1 µM B(α)P was found to be, significantly reduced as compared with scrambled siRNA (P = 0.035) in HT-29 cells (Fig. 6A). Relative mRNA expressions of IID in siRNA (IID) without and with 0.1 µM B(α)P were found to be significantly reduced (p = 0.025) as compared to scrambled controls in HCT-15 (Fig. 6B). Relative gene expression of group IVA at mRNA levels in siRNA (IVA) without and with 0.1 µM B(α)P concentration was found to significantly down-regulated (p = 0.021) in comparison to scrambled controls in HCT-15 (Fig. 6C). Thus, a significant inhibition in gene expressions of group IB, IID, and IVA, PLA₂ isoforms were observed in the presence of siRNA of specific PLA₂ gene (p < 0.05).

Effect of group IB, IID, and IVA PLA₂ gene silencing
Cell Viability:
Effects of B(α)P on cell viability after silencing the specific PLA2 genes are shown in Fig. 7 at 48 hr.

Figure-7A shows cell viability in group IB PLA2 transfected cells using IB siRNA. Viability of cells in scrambled siRNA control and siRNA (IB) without and with 0.1 µM B(α)P were found to be comparable respectively as compared to scrambled control in HT-29 cells (Fig. 7A). The percentage of cell viability after knockdown with IID PLA2 siRNA or scrambled siRNA control and siRNA (IID) without and with 0.1 µM B(α)P were found to be not significantly reduced as compared to scrambled control in HCT-15 cells (Fig. 7B). The cell viability in HCT-15 cells after the suppression of group IVA PLA2 gene using siRNA of scrambled siRNA control and siRNA (IVA) without and with 0.1 µM B(α)P were found to be comparable as compared to scrambled control (Fig. 7C). It was worth noting that values after treatment with B(α)P were statistically non significant to scrambled control.

Intracellular Ros:
ROS formation in the presence of group IB, IID and IVA siRNA in both cell lines at 48 hr is shown in Fig. 8. Total ROS production in scrambled siRNA control and siRNA (IB) without and with 0.1 µM of B(α)P in HT-29 cells were found to be 101 ± 3.1%, 86 ± 5.5% and 106 ± 7.3% respectively (Fig. 8A). ROS production in HCT-15 cells in the presence of scrambled siRNA control and siRNA (IID) without and with 0.1 µM of B(α)P siRNA (IID) were found to be 106 ± 6.6%, 97 ± 5.1% and 88 ± 4.6% respectively (Fig. 8B). Whereas, ROS production in the presence of group IVA siRNA with exposure to 0.1 µM B(α)P were 109 ± 10.3%, 104 ± 4.1%, and 147 ± 6.9% in scrambled siRNA control and siRNA (IVA) without and with 0.1 µM of B(α)P respectively as compared to scrambled control in HCT-15 cells (Fig. 8C). A statistically significant increase (p = 0.014) in ROS production was found only in IVA transfected cells when challenged with 0.1 µM B(α)P. Figure 8 (D, E, and F) shows mitochondrial ROS production after down-regulation of the PLA2 gene using siRNA and treating the cells with 0.1 µM B(α)P at 48 hr. ROS production in HT-29 cells transfected with group IB PLA2 gene using siRNA and treated to 0.1 µM B(α)P was 89 ± 6.4%, 81 ± 3.7%, and 89 ± 3.4% in scrambled siRNA control and siRNA (IB) without and with 0.1 µM of B(α)P respectively (Fig. 8D). Whereas ROS production in the presence of group IID PLA2 siRNA in HCT-15 cells was 121 ± 2.8%, 97 ± 10.3% and 92 ± 8.6% in
scrambled siRNA control and siRNA (IID) without and with 0.1 µM of B(α)P respectively (Fig. 8E). On the other hand, ROS production in the presence of group IVA siRNA with exposure to 0.1 µM B(α)P was 104 ± 12.5%, 99 ± 5.2%, and 96 ± 4.2% in scrambled siRNA control and siRNA (IVA) without and with 0.1 µM of B(α)P respectively in HCT-15 cells (Fig. 8F). However, all the values in the experimental groups mentioned above were statistically non-significant to scrambled control.

**SOR Production:**
Relative SOR production in the presence of group IB, IID and IVA siRNA in both cell lines at 48 hr is shown in Fig. 9. Relative SOR production in HT-29 cells transfected with group IB PLA₂ gene siRNA treated with 0.1 µM B(α)P in scrambled siRNA control and siRNA (IB) without and with 0.1 µM of B(α)P were found to be 92 ± 4.9%, 103 ± 9.6% and 116 ± 3.5% respectively (Fig. 9A). Whereas, SOR production in scrambled siRNA control and siRNA (IID) without and with 0.1 µM of B(α)P was 91 ± 8.0%, 86 ± 6.7%, and 90 ± 3.6% respectively in HCT-15 cells (Fig. 9B). However, the SOR production in HCT-15 cells in the presence of siRNA (IVA) was 96 ± 12.0%, 73 ± 10.7% and 69 ± 13.0% in scrambled siRNA control and siRNA (IVA) without and with 0.1 µM of B(α)P respectively (Fig. 9C). Like other parameters such as cell viability, ROS, mitochondrial ROS, etc in this case also the changes were non-significant to scrambled control.

**Discussion**
CS continues to remain one of the most important health hazards and it contributes extensively to many diseases including respiratory disorders characterized by inflammatory changes in the lungs [9, 10]. It is involved in many other cancers like pharynx, larynx, esophagus, etc. various studies also suggested the relationship between smoking and stomach, liver and colon cancer [11, 12]. However, the molecular and cellular mechanism involved in the pathogenesis of smoking-related colon cancer remains unknown.

CS is a very complex, multi-factorial stimulus with over 5300 identified [13]. Approximately 100 carcinogens, co-carcinogens, mutagens, and/or tumor promoters are present in CS [14]. One of the most prominent carcinogens in burned as well as, unburned tobacco, is benzo(α) [15]. The complex changes in cellular functions, morphology and gene expression caused by CS constituents that are
initiators as well as promoters of carcinogenesis [16], involve a combination of direct and indirect effects on cells and their components. We found that treatment with B(α)P resulted in a significant change in cell shape and size in both the cell lines (HCT-15 and HT-29 cells). There was prominent fragmentation, loss of cohesiveness, irregular shape and the cells appeared in clumps. Our present study is in check this word with an earlier report, on MCF-10A and MCF-12A cell lines which also showed these cellular changes after CSC treatment. These morphological changes may be due to multiples factors like altered cell membrane integrity caused by increased formation of ROS leading to changes in cytotoxicity, proliferation and apoptosis.

Cytotoxicity, an important factor in understanding the mechanism of action of chemicals on cells and tissues, may modulate the activity of other agents, including free radicals, oxidants, irritants and genotoxins [17]. These intracellular moieties have been reported to induce adverse effects in the body [18]. In this study, we observed that no cytotoxic effects of B(α)P at concentrations below 1 µM in HCT-15 and below 50 µM in HT-29 cells, but at higher concentrations, the cell viability decreased significantly. Similar observations have been reported earlier on the effects of B(α)P in other cell lines [19].

Cellular levels of ROS reflect a delicate balance between ROS production and detoxification. Despite the existence of such well-coordinated cellular ROS detoxification systems, the uncontrolled ROS production may overwhelm these defense mechanisms. Many previous studies have shown that aqueous cigarette tar extracts increase cellular production of ROS [20, 21] leading to increased pro-inflammatory gene expressions [22]. As cells respond to various agents and mediate the regulation of ROS through different mechanisms of H2O2, superoxide and mitochondrial ROS generation. It was of interest to elucidate the main mechanism of ROS mediated damage towards the B[a]P in the colon cells. Hence we used various fluorescent probes that detect the intracellular H2O2 using DCFH-DA, superoxide using DHE and mitochondrial ROS using DHR123. Our results clearly show that PLA2 IVA is identified in the intracellular H2O2 mediated oxidative stress. In this study, we have found that B(α)P induced intracellular ROS in both the colon cell lines (HCT-15 and HT-29). However, the extent of ROS production was more in HT-29 cells than in HCT-15 cells. Interestingly the induction of ROS, in HT-29
cells which had the origin from colorectal, human primary carcinoma of the colon was more active in producing ROS [23]. As intracellular ROS could function upstream or downstream of the mitochondria, we also determined the mitochondrial ROS production in these cells after exposure with B(α)P. It was found that the extent of generation of ROS in mitochondria of HT-29 cells was less as compared to HCT-15 cells. Besides this the extent of mitochondrial ROS generation in HT-29 cell was much less than the overall stimulation whereas, in HCT-15 cells the increase in overall and mitochondrial production of ROS was much less than in HT-29 cells. The possible explanation for such an observation could be the variation in mitochondrial antioxidant defense (enzymatic and non-enzymatic) system in the two cell lines, one of which (HT-29) is more resistant than the other (HCT-15) to the toxic materials.

Another pathway of regulating the superoxide radicals is through ubiquinol (QH\(_2\)) which has been shown to act as a reducing agent in the elimination of various peroxides in the presence of succinate [24]. Though like total ROS, SOR production by B(α)P was more in HT-29 than HCT-15 cells, the mitochondrial ROS production was more in HCT-15 cells. This finding indicates of better antioxidant status of HT-29 cells and is likely to be related to the stability of cells in response to toxic material B(α)P. If we closely look at the cell viability and ROS generation at the concentrations of Benzo pyrene used, both the cell lines showed the ROS generation using all the fluorescent dyes. However, the concentrations at which both the cell lines showed ROS generation was at 0.1µM for DCFH-DA and DHR123. It is clear from this result that the initiation of ROS starts at 0.1µM but to have the toxicity effect the dose of 0.1 µM B[α]P is not sufficient to elicit the damaging effect and only happens beyond the dose of 1 µM. In this study we observed that the exposure to B(α)P in colon epithelial cells induced an increase in the expression of phospholipase A\(_2\). sPLA\(_2\) isoforms produce inflammatory mediators that stimulate the expression of ICAM-1. Recently several studies have looked beyond the role of phospholipase enzymes in inflammation to probe their contribution to the pathogenesis of cancer [25–27]. As per our knowledge there is no study that has determined the status of PLA\(_2\) isoforms expression in colon cells after exposure with B(α)P. There are some studies that have
reported the expression of various PLA₂ isoforms in some cancers including colon cancer. However, the majority of these studies have looked at the expression of cPLA₂ only. Our study is different from all the previous studies as we have evaluated the expression of all PLA₂ isoforms as well as their modulation with B(α)P. In this study, expression of PLA₂ isoforms in both cell lines were treated with B(α)P, induction in the expression of PLA₂ isoforms was different in HCT-15 and HT-29 cells. Group IVC PLA₂ was not expressed in HT-29 cells at the control level as well as after treatment with B(α)P. Whereas, it was expressed in HCT-15 cells after treatment with B(α)P. PLA₂ IID and IVA group of sPLA₂ family was upregulated significantly in treated groups when compared to control in HCT-15 cells whereas group IB PLA₂ increased significantly with B(α)P treatment in HT-29 cells. Levels of mRNA expression of III, IVB, IVC, VI, X, aiPLA₂ and iPLA₂ groups were not affected in the cells after treatment with B(α)P.

Many previous studies documented the PLA₂ s such as cPLA₂, sPLA₂ group IIA, sPLA₂ group IID and sPLA₂ group X has been involved in colon tumor development [28, 29]. Our findings are similar to that of Valentine et al., 2000 [30] to some extent, wherein they found over-expression of cPLA₂ in 49% of colon carcinomas patients as well as in four colon cancer cell lines. These results coincide with the elevated expression of cPLA₂α in human colon adenocarcinoma [31]. On the other hand, cPLA₂ expression has been reported to be was diminished in azoxymethane-induced mouse colon tumors and knock-out of cPLA₂ enhanced colon tumor development [32]. But effects of PLA₂-knockdown observed in this study on CSC- and B(α)P-induced changes may be due to reversal of the process of cell morphology, cell viability, cell proliferation, cell membrane integrity, cell apoptosis, ROS production, mitochondrial ROS production and SOR formation in transfected cells by specific PLA₂ siRNA as well as in cells treated with selected concentration of B(a)P in HCT-15 and HT-29 cells. The underlying molecular mechanism involved in this process appears to be through sPLA₂ (group IID) and cPLA₂ (group IVA) in HCT-15 cells, whereas it occurs through sPLA₂ (group IB) in HT-29 cells. This observation clearly indicates that sPLA₂ isoforms are commonly affected PLA₂ in both these cell lines.
and inhibition of this isoform by the specific agents may play an important role in arresting the growth of colon cancer cells.

**Conclusion**

sPLA$_2$ appears to be the most common form of PLA$_2$ playing a role in the deleterious effects of B(α)P in HCT-15 and HT-29 colon cells.

**List Of Abbreviations**

B(α)P; Benzo(α)pyrene

cPLA2; Cytosolic phospholipase A2

CRC; Colorectal cancer

CS; Cigarette smoke

CSC; Cigarette smoke condensate

iPLA2; Independent phospholipase A2

MTT; 3-(4, 5- dimethylthiazol-2-yl)-diphenyltetrazolium bromide

PBS; Phosphate buffer saline

PLA$_2$; Phospholipase A$_2$

ROS; Reactive oxygen species

SOR; Superoxide radicals

sPLA$_2$; Secretory phospholipase A$_2$

**Declarations**

**Ethical Approval and Consent to participate:** Not applicable

**Consent for publication:** Not applicable.

**Availability of data and material:** Detail description of observations is mentioned in the result section.

**Competing interests:** The authors declare that they have no competing interests.

**Funding:** Indian Council of Medical Research, Govt. of India, New Delhi, for the award of Senior Research Fellowship (IRIS ID: 2010-09550) to Sanjeev Kumar Sharma. However, no funding is available for the project and publication.
Authors' contributions: SKS: Designing and executed the experiments as well as written the manuscript; SKY & US: Helped in performing the experiments; PV: supervised the experiments, SVR & KLK: Designed and supervised the whole experiments. All authors read and approved the final manuscript.

Acknowledgments: Authors would like to acknowledge Indian Council of Medical Research, Govt. of India, New Delhi, for the award of Senior Research Fellowship (IRIS ID: 2010-09550) to Sanjeev Kumar Sharma.
