ABSTRACT

Introduction: Detailed diagnosis, treatment planning and successful endodontic treatment require in-depth understanding of the root canal anatomy and its distinguishing features in various ethnic groups.

Objective: The aim of this study was to study the C-shaped canal morphology of mandibular second molars in Nepalese population by using clinical and radiographic analysis.

Methods: This descriptive cross-sectional study will be designed and implemented using records from dental records from January 2017 to January 2021. Out of 4680 cases, 1800 cases were evaluated as sample based upon inclusion and exclusion criteria. The prevalence of C-shaped root canals according to age, sex, and quadrant were calculated. The morphology of C-shaped root canals were assessed on the basis of radiographic appearance and clinical examination record. Descriptive statistics were presented as numbers and percentage. Chi-square test was used to check any association between variables. Level of significance was kept at 0.05.

Results: The prevalence of C-shaped canals was 0.105%(n=162) in second mandibular molar with highest prevalence was in young adult age group (18-25) and slightly higher in male cases than female. Unilateral cases (93.83%) of C-shaped was more prevalent than bilateral (6.17%). Group of age and site(unilateral/bilateral) variables were significantly associated with the prevalence of c-shaped canals.

Conclusions: Knowing the anatomical variation and prevalence of population we are treating is utmost important for favorable outcome. In comparison to the prevalence of other Asian countries like China, Korea the prevalence of C-shaped canal was comparatively less.

Keywords: C-shaped canal; morphology; Nepalese population; prevalence; second molar.

INTRODUCTION

Study of atypical root canal anatomy such as C-shaped might play a roadmap for successful root canal treatment.1 C-shaped canal configuration was first coined by Cooke and Cox in 1979.2 The variation of C-shaped root canal system appears to be genetically determined, and it has some relationship with ethnic origin.3 Manning et al has described the root canal anatomy of mandibular second molars, in which he stated that C-shaped root canals were first documented in 1908 and 1911, in the skeletal remains of the Neanderthal race, which were predecessors of the Mongoloid race that includes Asian populations.3

Though most commonly found in mandibular second molars,4-11 the C-shaped canal configuration may also occur in mandibular premolars,12-16 maxillary molars,17,18 and mandibular third molars.19,20

The Nepalese population is generally considered to be a hybrid of several ethnic groups with characteristics of Caucasian, Mongoloid, and Negroid races, which is generally referred to as the Dravidian group.21

Although literature shows studies on root canal morphology of molars and premolars in different Asian population, there is scarcity of data on Nepalese population.
Hence, the aim of this study was to evaluate the prevalence of C-shaped canal morphology of mandibular second molars in Nepalese population by using clinical and radiographic analysis. The result of this study will provide a reliable guidance for endodontic treatment and enhancing its success rate of mandibular second molar.

METHODS

This cross-sectional retrospective study was approved by the Institutional Review Committee (IRC) of Universal College of Medical Sciences, Bhairahawa, Nepal (UCMS/IRC/158/21). The study was designed and implemented using dental records from record section of the Department of Endodontics, Universal College of Medical Sciences, Bhairahawa, Nepal for the duration of January 2017 to January 2021. Only the full record of the patients who were evaluated by radiographic and clinical examination, respectively and data entered appropriately were taken as sample. Identity of all the patients in sample were strictly kept confidential.

The patients within the age group of 18-60 years were included in sample size with the pulpal diagnosis of irreversible pulpitis and symptomatic or asymptomatic apical periodontitis of second molar. Whereas, the patients were excluded on the basis of: cases with open apices, root resorption or calcification, previous root canal treated teeth and improper radiographic images and incomplete clinical records.

The sample size was calculated by,

\[ n = \frac{Z^2 \times p \times (1-p)}{e^2} \]

= \frac{2.6^2 \times 0.05 \times (1-0.05)}{0.02^2}

= 4225

where,

\[ Z = 2.6 \] at 99% Confidence Interval
\[ p = 50\% \] assumed prevalence of C-shaped canal
\[ q = 0.5 \times (1-p) \]
\[ e = 0.02 \] at 2% margin of error

The prevalence of C-shaped root canals according to age, sex, and quadrant were calculated. The morphology of C-shaped root canals was assessed on the basis of radiographic appearance and clinical examination record. To evaluate the radiograph, two endodontists independently evaluated the images twice, with a week interval between the assessments. If there were disagreements between them, a radiologist with endodontic experience was asked to perform a third evaluation and then reached a final consensus. All the evaluators were calibrated by analyzing 20 random cases of mandibular premolars based on the same criteria and variants. The clinical evaluation was done based on architecture of floor of access cavity by using magnifying loupes (Zumax Medical Co, Ltd, China). The radiographic assessment was done at three different angulations; perpendicular, mesial and distal angulations.

Descriptive statistics were presented as numbers and percentage. Chi-square test was used to check any association between variables. Level of significance was kept at 0.05.

RESULTS

Out of 4680 cases evaluated for root canal treatment only 1800 cases were included in the study after taking into consideration of inclusion and exclusion criteria. The prevalence of C-shaped canals was 0.105% \( (n=162) \) in second mandibular molar. Among which highest prevalence was in young adult age group (18-25) as shown in (Table 1) and slightly higher in male cases than female as shown in (Table 2). Unilateral cases (93.83%) of C-shaped was more prevalent than bilateral (6.17%) as shown in (Table 3). Table 4 suggested prevalence of C-shaped canal is significantly associated with age group and site whereas gender type was not associated.
DISCUSSION

Recognition of variations in root canal anatomy is an essential prerequisite for successful endodontic diagnosis and treatment. The complexities of internal anatomy are often masked by the external surfaces, which have a relatively simple and uniform anatomy. C-shaped canal is a single ribbon-shaped orifice with a 180° arc (or more), which, in mandibular molars, starts at the mesiolingual line angle and sweeps around the buccal to the end at the distal aspect of the pulp chamber. Below the orifice level, the root structure can harbor a wide range of anatomic variations. These can be classified into two basic groups: (1) those with a single, ribbon-like, C-shaped canal from orifice to apex and (2) those

| Table 1: Prevalence of C-shaped canal in different age groups. |
|---------------------------------|
| Age Group | Cases | Percentage |
| 18-25 | 62 | 38.27% |
| 25-44 | 58 | 35.80% |
| 44-60 | 42 | 25.93% |
| Total | 162 | 100% |

| Table 2: Prevalence of C-shaped canal gender wise. |
|---------------------------------|
| Gender | Cases | Percentage |
| Male | 84 | 51.85% |
| Female | 78 | 48.15% |
| Total | 162 | 100% |

| Table 3: Prevalence of C-shaped canals site wise. |
|---------------------------------|
| Side | Cases | Percentage |
| Right | 86 | 53.09% |
| Left | 66 | 40.74% |
| Both | 10 | 6.17% |
| Total | 162 | 100% |

| Table 4:Association of variables with C-shaped cases |
|---------------------------------|
| Variables | Categories | C- Shaped Count | p-value |
| Gender | Male | 857 | 84(51.85%) | 0.9 |
| Female | 781 | 78(48.15%) |
| Age Group | 18-25 | 589 | 62 (38.27%) | <0.05 |
| 25-44 | 813 | 58 (35.80%) |
| 44-60 | 236 | 42 (25.93%) |
| Site | Unilateral | 1402 | 152(93.83%) | 0.003 |
| Bilateral | 236 | 10(6.17%) |

Chi-square test at 0.05 level of significant
with three or more distinct canals below the C-shaped orifice. C-shaped canals with a single belt of canal are generally fortunate finding. The configuration presents with variations in both the number and location of the canal(s), as the canal(s) courses from the coronal to the apical third. The complexity of this canal configuration such as presence of a fin or web connecting the individual root canals proves to be a challenge with respect to debridement and obturation and possibly the prognosis during root canal therapy. Hence, recognition of a C-shaped canal configuration before treatment can facilitate effective management, which will prevent irreparable damage that may put the tooth in severe jeopardy.

The C-shaped canal is more common in the Asian population specifically in Korean with its reported prevalence ranging from 31% to 44.5%. But in the current study, the prevalence of C-shaped canals were observed only 0.105%. Differences between populations in the prevalence of C-shaped root canal systems emphasize the influence of ethnicity on the root canal anatomy of mandibular second molars. C-shaped root canals were significantly less prevalent in the age group of 44-60 years than in the 25-44 years age group, and patients in the over 51 age group were less likely to have C-shaped root canals than those in other age groups which was consistent with previous studies. It is our conjecture that as C-shaped canals are anatomically complex and more difficult for performing root canal treatment than other types of root canals, the incidence of extraction of teeth with C-shaped canals increases with age, resulting in a decreased prevalence with increasing age.

In present study, unilateral (93.83%) presence of C-shaped canal was higher than bilateral (6.17%) which is in contrast to the study done by Sung Eun et al which showed higher bilateral prevalence. This discrepancy might be due to variable ethnic background and uniform large sample size. As our sampling frame is amalgamation of mixed community, culture and race.

Limitation of the study: Data were totally relied upon record book. The configuration type of C-shaped could not be assessed as it was retrospect. And moreover, the radiographic data were simple radiovisiography record and clinical assessment record was based upon loupes and naked eye. For more accurate and precise analysis cone beam computed tomography (CBCT) and Operating microscope would have been better tools. Indeed it would add extra cost and radiation exposure burden to the patients.

In light of the present study results, clinicians should consider age, sex, and ethnicity when determining root canal morphology prior to root canal treatment. The results of this study furnish useful information for C-shaped canal anatomy for effective endodontic treatment, serving as a valuable diagnostic tool in endodontics.

CONCLUSIONS

Understanding the prevalence of morphologic variation of root canal system of the any locality is baseline requirement for any clinician for better presumptive visualization and successful treatment outcome. The present study will certainly instigate the clinician to study the prevalence of C-shaped canals in different regions of Nepal.
