(Dated: June 17, 2016)

We study the effect of electronic Coulomb correlations on the vacancy formation energy in paramagnetic $\alpha$-Fe within ab initio dynamical mean-field theory. The calculated value for the formation energy is substantially lower than in standard density-functional calculations and in excellent agreement with experiment. The reduction is caused by an enhancement of electronic correlations at the nearest neighbors of the vacancy. This effect is explained by subtle changes in the corresponding spectral function of the $d$-electrons. The local lattice relaxations around the vacancy are substantially increased by many-body effects.

PACS numbers: 61.72.jd, 71.10.-w, 71.27.+a, 75.50.Bb

Point defects, such as vacancies, play an important role for the mechanical and thermodynamic properties of materials[1]. However, the experimental determination of vacancy formation or migration energies is difficult. Even the best available techniques, the differential dilatometry and the positron annihilation spectroscopy, suffer from large error bars, and the discrepancies between different measurements on one and the same material may be significant. Therefore, ab initio theoretical calculations are an indispensable tool for developing a better understanding of the defect properties of materials[2].

Early density functional theory (DFT) calculations in the local density approximation (LDA) have predicted formation energies of vacancies in simple metals in good agreement with experiment[3, 4]. Despite a large body of successful calculations, it has been recognized that the nice agreement with experiment could often be the effect of the cancellation of errors in the exchange and correlation parts of the density functional [5]. As has been discussed by Ruban [6], despite the structural simplicity of vacancies, their energetics is still one of the least reliable physical properties determined in first-principles calculations.

In transition metals, where the open $d$ shells are often poorly described in LDA or the generalized gradient approximation (GGA), the quality of results of DFT calculations for point defect properties is rather unpredictable and strongly material-dependent. There have been several attempts to improve the available functionals (see, e.g., Refs. [7–10]). We notice that the predicted vacancy formation energies seem to be especially poor for $3d$ transition metals, for which many-body effects are fairly important, in particular in the paramagnetic state and body-centered cubic (bcc) crystal structure[11]. Likewise, DFT has limitations for point defect calculations in correlated lanthanide or actinide oxides with $4f$ or $5f$ electrons, for example in the case of uranium oxides used in the nuclear industry[12].

Among the $3d$ transition metals, iron is a particularly complex system, where the strength of electronic correlations is very sensitive to the lattice structure and magnetic state. However, from a practical point of view, vacancies in iron and steels are of particular interest because they affect a number of important characteristics of the metal, e.g. toughness and ductility. Iron’s low-temperature ferromagnetic bcc $\alpha$ phase is a weakly-renormalized Fermi liquid[13] well described within DFT [14–16]. However, the same $\alpha$-Fe in the high-temperature paramagnetic phase exhibits a strongly-correlated non-Fermi-liquid behavior [17–19] with DFT calculations failing to describe its structural parameters (lattice constants, bulk modulus, or even the shape of the crystal) [18]. The low-temperature paramagnetic hexagonal $\epsilon$ phase stabilized by pressure is also rather strongly correlated [15] (though less so as compared to paramagnetic $\alpha$-Fe), exhibiting a large electron-electron scattering contribution to the resistivity [20] as well as unconventional superconductivity [21, 22]. All this hints at a strong sensitivity of many-body effects in Fe to local disturbances of the crystalline order (e.g., to point defects) that cannot be captured within standard DFT. Indeed, extensive DFT calculations of $\alpha$-Fe [23–26] consistently predict a monovacancy formation energy about 30 to 40 % higher than the measured value. In contrast to other $3d$ metals, this formation energy has been somewhat reliably determined thanks to extensive experiments [27–31].

The deficiencies of standard DFT to describe $\epsilon$-Fe and paramagnetic $\alpha$-Fe have been successfully corrected by combining it with a dynamical mean-field theory (DMFT) [32, 33] treatment of the local repulsion be-
tween $3d$ electrons. Ab initio calculations using this DFT+DMFT approach [34, 35] were able to reproduce the ground-state properties and phonon spectra of the $\alpha$-phase [18, 36] as well as the equation of state of $\epsilon$-Fe [13]. It is thus likely that an explicit treatment of many-body effects within DMFT will also correct the severe problems of DFT in describing point defects in iron.

Hence, in the present work we have developed the state-of-the-art DFT+DMFT method [37–40] into a scheme for studying vacancy properties. We have applied our technique to a single vacancy in $\alpha$-Fe, computing the electronic structure around the vacancy as well as the vacancy’s formation energy, taking into account local lattice distortions around the defect. We do not treat here the high-temperature face-centered cubic (fcc) phase, nor temperatures close to the melting point, where the influence of the (anharmonic) lattice vibrations may play a crucial role [5, 10, 41] and the bcc phase is stabilized again. Compared to DFT-LDA, a significant reduction of the theoretical formation energy is obtained, with calculated values in remarkable agreement with experimental estimates [27–31]. We trace back this reduction to rather subtle effects of the vacancy on the local density of states and hybridization with its nearest neighbors.

We model a single vacancy in bcc Fe using the $2 \times 2 \times 2$ and $3 \times 3 \times 3$ cubic supercells represented in Fig. 1, with the vacancy placed at the origin of the supercells. We compute the vacancy formation energy from the supercell total energy using the standard formula

$$E_{\text{vac}}^f = E_{\text{vac}}^N (N-1) - \frac{N-1}{N} E_{\text{no vac}}^N (N),$$

where $N$ is the number of atoms in the ideal supercell, $E_{\text{no vac}}^N(N)$ is the total energy of the ideal supercell containing $N$ atoms and no vacancy, and $E_{\text{vac}}^N(N-1)$ is the total energy of the same supercell with a vacancy (hence $N-1$ atoms). $N$ is 16 in the $2\times2\times2$ supercell and 54 in the $3\times3\times3$ supercell, corresponding to vacancy concentrations of respectively 6.25 and 1.85%, respectively.

Our calculations have been carried out using a fully charge self-consistent implementation of DFT+DMFT [42, 43] based on the TRIQS package [44, 45]. This implementation is based on the full potential linearized augmented plane-wave (FLAPW) Wien2k code [46]. The on-site density-density interaction between those orbitals is parametrized by the Slater parameter $F_0 = U = 4.3$ eV and the Hund’s rule coupling $J = 1.0$ eV that were previously used in the DFT+DMFT calculations of $\alpha$ and $\epsilon$-Fe of Ref. [13]. The calculation of a vacancy formation energy using supercells with seven inequivalent atomic sites – which, to the best of our knowledge, has hitherto never been achieved – has become possible thanks to the use of a continuous-time quantum Monte-Carlo (CTQMC) hybridization expansion algorithm [47] in the segment representation for the solution of the local impurity problems (Lechermann et al. have reported about the effect of vacancies on magnetism within DFT+DMFT [48, 49]). All DFT+DMFT calculations were performed at a temperature of 1162K in the paramagnetic phase of $\alpha$-Fe, at its experimental lattice parameter of 2.86 Å. The experimental volume of $\alpha$-Fe was almost exactly reproduced in Ref. [13] with identical calculation parameters.

The vacancy formation energies obtained within DFT+DMFT together with different DFT results and experimental values are shown in Fig. 2 (see also Table I of the Supplementary Material [50]). The resulting value for $E_{\text{vac}}^f$ in DFT+DMFT is 1.77 eV for the unrelaxed 54-atom supercell with lattice relaxations reducing it further to $E_{\text{vac}}^f = 1.56 \pm 0.13$ eV, in excellent agreement with the mean experimental value of about
1.6 eV. We also calculated \( E_{\text{vac}}^t \) within DFT+DMFT for the unrelaxed ferromagnetic phase obtaining a higher value of 2.45±0.15 eV. Experiments indeed seem to confirm that \( E_{\text{vac}}^t \) in the ferromagnetic phase should be larger than in the nonmagnetic one[30, 31], though direct low-temperature measurements of \( E_{\text{vac}}^t \) in the ferromagnetic phase with positron annihilation spectroscopy are difficult and all reported values have been extrapolated from high-temperature measurements.

DFT (GGA) calculations assuming ferromagnetic bcc Fe predict a significantly larger value \( E_{\text{vac}}^t \) of 2.70 and 2.50 eV for an unrelaxed and a fully relaxed cell, respectively. Hence, one sees that many-body effects included within DMFT reduce \( E_{\text{vac}}^t \) for the paramagnetic phase by about 0.9 eV. The impact of correlation effects for ferromagnetic \( \alpha \)-Fe is less significant, in agreement with the predicted suppression of dynamic correlations in this phase[13]. The vacancy formation energies obtained with nonmagnetic LDA or GGA calculations are closer to the measured values, with \( E_{\text{vac}}^t \approx 2.05 \text{eV} \) in GGA. They have, however, a limited physical meaning: DFT in general fails dramatically for the paramagnetic phase, which is reflected by the fact that \( \alpha \)-Fe is not dynamically stable and the predicted lattice parameter would be significantly smaller in nonmagnetic LDA or GGA. Hence, using our relaxed positions in a nonmagnetic DFT calculation gives an (absurd) negative vacancy energy, as shown in Fig. 4ab. \( t_{2g} \) states, but also \( e_g \) states to a lesser extent, become more strongly correlated (less coherent) with a larger \( \text{Im} \Sigma(i\omega) \). This difference almost vanishes for the self-energy of the atoms further than the nearest neighbor, in agreement with the variation of the interaction energy shown in Fig. 3. Stronger correlations on the atoms near the vacancy imply that a more correct description of the 3d electrons of the Fe atoms in DFT+DMFT, already important to predict the crystal structure and lattice parameter, is especially crucial when estimating the energetics of the vacancy and indeed leads to a smaller formation energy. Note that the self-energies are slightly atom-dependent even in the absence of a vacancy in our calculations, due to an artificial symmetry-breaking in the supercell in DFT calculations and the non-rotational invariance of the density-density Hubbard Hamiltonian. However, we compare self-energies and interaction energies in a consistent, atom-to-atom way.

The enhancement of the nearest-neighbor self-energy can be traced back to a change in the hybridization function. As can be seen in Figure 4d, the imaginary-frequency hybridization function, in particular for the \( t_{2g} \) states, is reduced at low frequencies for the atom near the vacancy. This reduction is due to an increase in the corresponding \( t_{2g} \) partial density of states (DOS) in the vicinity of the Fermi level, \( E_F \), as one can see in Fig. 4c. A larger DOS at \( E_F \) induces a suppression of low-energy hopping leading to stronger correlation[19, 52]: at the first iteration of DMFT, \( \text{Im} \Delta(i\omega) \approx -\pi \rho_F/\left[ \text{Re} G_{\text{loc}}(i\omega)^2 + (\pi \rho_F)^2 \right] \approx -1/(\pi \rho_F) \), with \( \rho_F \) the LDA DOS. The enhancement of
FIG. 4: Imaginary part of the Matsubara self-energies for (a) the vacancy nearest neighbor and (b) central atom in the 3x3x3 supercell with a vacancy present (red, full) or without it (blue, dashed). Correlations become stronger on the atom nearest to the vacancy while the difference between $e_g$ and $t_{2g}$ is strongly reduced. c) LDA density of states around the Fermi level and d) Hybridization function on the Matsubara axis for the nearest neighbors (blue, full) to the vacancy, and for the central atom (black, dashed). The full Fe 3$d$ DOS is shown in the Supplementary Material [50] (Color online).

We performed a relaxation of the atoms around the vacancy in two steps, in order to reduce the computational effort. Indeed, to consistently calculate atomic forces in DFT+DMFT it is not sufficient to calculate them in the DFT part of the scheme[53]. We first performed the full relaxation in spin-polarized GGA (at its corresponding theoretical volume) obtaining a shift of the first coordination shell towards the vacancy by about 4%, and a shift of the second coordination shell away from the vacancy by about 1.5%. All the other atoms do not move significantly. These GGA-relaxed positions are in agreement with previous calculations[23]. Then the positions of the two first nearest neighbors were relaxed within DFT+DMFT. In Fig. 5 we show the total energy (minus an offset depending on the method used, GGA or DFT+DMFT) of the supercell as a function of the relaxed position of the nearest and second nearest neighbor of the vacancy. Each site was moved independently, preserving the symmetry of the cell, while the positions of others were fixed at their fractional GGA values. We obtain the following results: The first nearest neighbor relaxes by another 1.8% towards the vacancy, for a total relaxation of 5.7% inwards changing the total energy by about 0.1 eV. One sees that many-body effects have a significant impact on the nearest-neighbor relaxation, enhancing it by almost 50%. Meanwhile, the second nearest neighbor relaxes back towards the vacancy by 0.8%, for a total relaxation of 0.7% outwards, with a negligible change in the total energy when compared to the GGA relaxed position. Overall, relaxing the two first coordination shells in full DFT+DMFT reduces the vacancy formation energy by 0.21 eV.

In conclusion, we have shown that local many-body effects are crucial to explaining a relatively low vacancy formation energy in α-Fe. The presence of a vacancy induces rather subtle changes in the local electronic structure of its surroundings, leading to a moderate increase in the strength of correlations at neighboring sites. This moderate increase has, however, a very significant impact on the vacancy energetics. When the effect of local relaxations is included, the calculated vacancy formation
energy is reduced by about 0.9 eV compared with the corresponding DFT value and is in excellent agreement with experiment. The predicted magnitude of nearest-neighbor relaxations is about 50% larger compared to the one obtained within DFT. This remarkable sensitivity to correlation effects is most probably pertinent to other types of defects in iron that are of the crucial importance for mechanical properties and thermodynamics of steels, e.g. interstitial sites, stacking faults and dislocations.

SUPPLEMENTARY MATERIAL

In this supplementary material, we provide additional details concerning the supercell DFT+DMFT scheme set up for the calculation of the vacancy formation energies, as well as additional support for the physical picture presented in the main text.

DETAILS OF THE METHODOLOGY

Our procedure is to take as a starting point a converged DFT calculation, using the full potential linearized augmented plane-wave (FLAPW) Wien2k code [46], which is then used to perform charge self-consistent DFT+DMFT. We use a k-point mesh with 8x8x8 points for the 16 atom supercell, and 4x4x4 points for the 54 atom supercell. GGA calculations are done with the PBE96 functional. Atomic sphere radii (RMTs) are reduced to 2.12 from the default value of 2.37 to allow for the experimental volume. We show that while the GGA reduces the on-site electron-electron interaction. We take the mean-field approximation for

\[ H = H^{LDA} + H^U - H^{DC} \]

where

\[ H^U = \sum_{m\neq m'} U_{mm'}^{\sigma\bar{\sigma}} n_{mm'} \delta_{\sigma\bar{\sigma}} + \sum_{m \neq m'} U_{mm'}^{\sigma\bar{\sigma}} n_{mm'} \delta_{\sigma\bar{\sigma}} \]

with

\[ U_{mm'}^{\sigma\bar{\sigma}} = U_{mm'mm'} \]

\[ J_{mm'} = U_{mm'mm'} \]

\[ U_{mm'}^{\sigma\bar{\sigma}} = U_{mm'mm'} - J_{mm'} \]

Here, \( U \) is the full Slater parameterized interaction matrix, and \( H^U \) is the density-density part of the full Slater Hamiltonian. \( H^{DC} \) corrects the double counting of interactions, as both \( H^U \) and \( H^{LDA} \) contain a part of the on-site electron-electron interaction. We take the around mean-field approximation for \( H^{DC} \).

In the calculations for the system with a vacancy, the DFT self-consistency condition corresponds to a set of seven equations, one for each inequivalent atom \( \alpha \). They require the impurity Green’s functions \( G_{\alpha}^{\text{imp}}(i\omega_n) \) to equal the respective projections of the lattice Green’s functions:

\[ G_{\text{imp}}^{\alpha}(i\omega_n)_{\delta\delta} = \sum_{\mathbf{k},\nu\nu'} P_{\ell\mu,\nu}(\mathbf{k}) G_{\nu\nu'}(\mathbf{k},i\omega_n) \left[ P_{\ell\mu',\nu'}(\mathbf{k}) \right]^* \]

where \( P_{\ell\mu,\nu}(\mathbf{k}) \) denotes the scalar product between the Kohn-Sham state \( \langle \ell\mu | k \rangle \) and the local orbital \( | \nu \rangle \) on atom \( \alpha \). The (inverse) correlated Green’s function in the Kohn-Sham basis is given by

\[ \langle G^{-1}(\mathbf{k},i\omega_n)_{\nu\nu'} \rangle \]

\[ = \langle i\omega_n + \mu - \varepsilon_k^\nu \rangle \delta_{\nu\nu'} - \Sigma_{\nu
u'}(\mathbf{k},i\omega_n), \quad \text{(7)} \]

where \( \varepsilon_k^\nu \) are the Kohn-Sham energies and \( \Sigma_{\nu\nu'}(\mathbf{k},i\omega_n) \) is the unfolded self-energy

\[ \Sigma_{\nu
u'}(\mathbf{k},i\omega_n) = \sum_{\alpha,mm'} \left[ P_{\ell\mu,\nu}(\mathbf{k}) \right]^* \left[ \Sigma_{\alpha}^{\alpha}(i\omega_n)_{\delta\delta} \right]_{\delta\delta} \]}

with

\[ \left[ \Sigma_{\alpha}^{\alpha}(i\omega_n)_{\delta\delta} \right]_{\delta\delta} = \left[ \Sigma_{\text{imp}}^{\alpha}(i\omega_n)_{\delta\delta} \right]_{\delta\delta} - \left[ \Sigma_{\text{DC}}^{\alpha} \Sigma_{\delta\delta} \right]_{\delta\delta} \]}

being the difference between the impurity self-energy \( \Sigma_{\text{imp}}^{\alpha}(i\omega_n) \) and the double-counting correction \( \Sigma_{\text{DC}}^{\alpha} \).

Finally, the interaction energy is computed as

\[ E_{\text{int}} = \frac{1}{2} \sum_{i,j} U_{ij} \langle n_i n_j \rangle - H^{DC} \]}

The temperature is \( T = 1162 K \) \( > T_{\text{curie}} \), where bcc Fe is paramagnetic.

About 15 iterations of DFT+DMFT are needed before reaching convergence in the DFT+DMFT cycle. A further averaging of the total energy values is required to obtain precise enough values. In practice, at least 50 more cycles are needed, and the statistical uncertainty

\[ E_{\text{int}} = \frac{1}{2} \sum_{i,j} U_{ij} \langle n_i n_j \rangle - H^{DC} \]}

where

\[ H = H^{LDA} + H^U - H^{DC} \]
shown in Table I and Fig. 1 of the main text is the empirical standard deviation of the value over these iterations. This uncertainty increases with the supercell size.

Our $2 \times 2 \times 2$ and $3 \times 3 \times 3$ supercells have an overall cubic symmetry. However, the presence of a vacancy still breaks the on-site cubic point group symmetries for all iron atoms apart from the central one. For those atoms the Wien2k code uses local coordinate frames chosen in such a way as to have the highest possible on-site symmetry. Subsequently, our impurity problems are also solved for those local coordinates. Hence, a corresponding inverse rotation should be applied to the resulting self-energies if one wishes to compare them with that of perfect bcc Fe. The later is, of course, obtained for the standard coordinate frame with $x$, $y$, and $z$ axes along the cube edges. However, because we are using a density-density Hamiltonian instead of the full rotationally-invariant one, the self-energies obtained for those local frames are still somewhat different from that of perfect bcc iron even after the inverse rotation. Hence, in our calculations of the ideal supercells we employed the same local coordinate frames as for the supercells with vacancy in order to avoid spurious contributions of those rotations to the vacancy formation energy. Furthermore, we verified that the off-diagonal elements in the Green’s functions stay small, so that we could neglect them.

**VACANCY FORMATION ENERGIES**

In Table I we list the vacancy formation energy in bcc Fe obtained by different theoretical approaches and experiments. Figure 2 of the main text corresponds to a graphical representation of these data.

**DENSITY OF STATES OF IRON $e_g$ AND $t_{2g}$ ORBITALS**

The density of states of figure 5 in the main part is shown below for the full energy range containing the Fe $3d$ bands.

Table I: Vacancy formation energies. The statistical uncertainty shown is the empirical standard deviation of the value over the last 50 iterations.

| Method                           | $E_{fvac}$ (eV) | Uncertainty (eV) |
|----------------------------------|-----------------|------------------|
| $2 \times 2$ supercell           |                 |                  |
| LDA (PM)                         | 2.50            | $< 10^{-2}$      |
| GGA (PM)                         | 2.24            | $< 10^{-2}$      |
| GGA (FM)                         | 2.45            | $< 10^{-2}$      |
| DFT+DMFT                         | 1.90            | ±0.097           |
| $3 \times 3$ supercell           |                 |                  |
| LDA (PM)                         | 2.33            | $< 10^{-2}$      |
| GGA (PM, relaxed)                | unstable        |                  |
| GGA (FM, relaxed)                | 2.06            | $< 10^{-2}$      |
| GGA (FM, relaxed)                | unstable        |                  |
| DFT+DMFT                         | 1.77            | ±0.14            |
| DFT+DMFT (FM GGA relaxed)        | 1.66            | ±0.15            |
| DFT+DMFT (FM DMFT relaxed)       | 1.56            | ±0.13            |
| DFT+DMFT (FM DMFT)               | 2.45            | ±0.15            |
