Abstract—The effect of aspirin on the prostacyclin (PG12) production of rat aorta was investigated, and the influence of sex hormones on the effect of aspirin was studied by the treatments of hormone administration, ovariectomy and castration. There was no significant sex difference in the arterial production of PG12 between male and female rats. However, the PG12 production was decreased with aspirin treatment, and the effect of aspirin was more efficient in male rats. The inhibitory effect of aspirin was reduced in the rats treated with estradiol and the castrated male rats, but it was potentiated in the rats treated with testosterone and the ovariectomized female rats. These results suggest that sex hormones may regulate the effect of aspirin on the PG12 production in the aorta.

Aspirin has been reported to be an effective antithrombotic agent in clinical trials (1–3) and in animal experiments (4). However, the antithrombotic effect of aspirin was found to be more effective in males than in females (2, 4).

That effect of aspirin is attributed to its inhibitory effect on PG12 synthesis; aspirin is considered to acetylate cyclooxygenase, an enzyme involved in PGs synthesis (5, 6). PG12 is the main product of the PGs in aorta (7). Chang et al. (8, 9) reported that estradiol stimulated the PG12 production in cultured smooth muscle cells of rat aorta and promoted the PG12 production in intact rats. Nakao et al. (10) showed that testosterone suppressed the PG12 production in cultured rat aortic smooth muscle cells.

In this report, the sex difference in the effect of aspirin and the influence of sex hormones in the inhibitory effect of aspirin on PG12 production were investigated.

Materials and Methods
Materials: Aspirin was obtained from Sanko Seiyaku Kogyo Co. Ltd., testosterone (4-androsten-17β-ol-3-on) and estradiol (1, 3,5-Oestratrien-3,17β-diol) from Fluka AG, ADP and arachidonic acid from Sigma, and [3H]-arachidonic acid (78 Ci/mmol) and [3H]-6-keto-prostaglandin F1α (120 Ci/mmol) from New England Nuclear. PG12 and PGH2 were given by Ono Yakuhin Kogyo Co. Ltd.

Animals: Wistar strain rats of both sexes were used for this study. At 6 weeks of age, the female rats were anesthetized with ether and then bilaterally ovariectomized via the back route. The male rats were anesthetized with ether and then bilaterally castrated via the ventral route. All rats were housed in a temperature-controlled room with a fixed lighting schedule (a.m. 7:00–p.m. 7:00) and allowed free access to standard laboratory food (Oriental Yeast Co. Ltd.) and water.

Administration of sex hormones: Testosterone or estradiol was dissolved in corn oil. Three days after the operation, the rats were treated with either 5 mg/kg testosterone or 10 μg/kg estradiol at intervals of three days from 6 weeks to 10 weeks. Control rats were given 1.0 ml/kg corn oil at the same interval from 6 weeks to 10 weeks.

Drug: Aspirin was suspended in 0.1% carboxymethylcellulose sodium salt solution for the p.o. administration. The dose levels
were 20, 50 and 100 mg/kg.

**Preparation of aortic tissues:** At an hour after administration of aspirin, the animals were sacrificed by bleeding from common carotid arteries, and the thoracic aortae were quickly isolated and kept in Krebs-Ringer Bicarbonate buffer (pH 7.4).

**Measurement of PGI₂ production:** The aortae were incubated in 50 mM Tris HCl buffer (pH 7.4) at 22°C for 2, 5, 10, 15, 20 and 30 min. The production of endogenous PGI₂ was determined by the modified method of Harada et al. (11, 12). The aorta was mechanically stimulated before each incubation by holding the strip with two forceps and gently stretching the strip ten times within 20 sec. The amounts of PGI₂ released in the medium were immediately bioassayed as the inhibitory activity against ADP-induced human platelet aggregation (13). The amount of PGI₂ increased time-dependently for the first 10 min and then decreased, so the aortae were incubated for 10 min. The content of PGI₂ was expressed as ng/mg of wet tissue, using synthetic PGI₂ as the standard.

**Measurement of PGI₂ production from exogenous arachidonic acid:** The aortae were incubated in Tris HCl buffer containing 1.0 μg/ml arachidonic acid at 37°C for 2 min. The PGI₂ production was immediately determined as described under “Measurement of PGI₂ production”.

**Measurement of PGI₂ production with addition of PGI₂ as a substrate:** The aortae were incubated in Tris HCl buffer containing 0.5 μg/ml PGH₂ at 37°C for 2 min. The PGI₂ production was determined by the above-described method of bioassay.

**Determination of 6-keto-PGF₁α production from [³H]-arachidonic acid:** The aortae were incubated in Tris HCl buffer containing 2 μCi [³H]-arachidonic acid at 37°C for 20 min. PGI₂ was assayed as its hydrolysis product, 6-keto-PGF₁α. The radioactivity of 6-keto-PGF₁α was determined by the modified method of Sun et al. (14).

**Measurement of PGI₂ production after addition of aspirin in vitro:** The aortae were preincubated with aspirin (2.0, 4.0, 6.0 and 10.0 μg/ml) in Tris HCl buffer (1.0 ml/2.5 mg tissue) at 22°C for 10 min and rinsed with Tris HCl buffer. Then they were incubated in Tris HCl buffer at 22°C for 10 min, and this incubation medium was measured for the PGI₂ production as described under “Measurement of PGI₂ production”. In the study of interaction of aspirin with sex hormones, 1.0 μg/ml testosterone and 1.0 ng/ml estradiol were used. The aortae were preincubated with aspirin (6 μg/ml) and testosterone or estradiol in Tris HCl buffer (1.0 ml/2.5 mg tissue) at 22°C for 10 min.

**Results**

**Effect of aspirin on PGI₂ production from endogenous arachidonic acid**

Figure 1 shows the inhibitory effect of aspirin on the PGI₂ production. In the control group, no sex difference was found in the PGI₂ production. In aspirin-treated group, the PGI₂ production was decreased in a dose-dependent manner. Aspirin at a dose 20 mg/kg did not efficiently decrease the PGI₂ production in female rats. Aspirin at a dose 50 mg/kg significantly decreased the PGI₂ production and more significantly decreased it in male rats. Furthermore, aspirin at 100 mg/kg completely inhibited the PGI₂ production.
in both sexes of rats (data not shown).

Effect of aspirin on PG\(_I_2\) production from exogenous arachidonic acid

Figure 2 shows that aspirin inhibited the PG\(_I_2\) production with the addition of arachidonic acid as a substrate. In the control group, there was no significant sex difference in the PG\(_I_2\) production, but the PG\(_I_2\) production in females was slightly larger than in males. In the aspirin-treated group, aspirin dose-dependently decreased the PG\(_I_2\) production. These results agree with those on the PG\(_I_2\) production from endogenous arachidonic acid. The effect of aspirin was more efficient in males than in females.

Figure 3 shows that aspirin inhibited the 6-keto-PGF\(_{1\alpha}\) release from [\(^3\)H]-arachidonic acid used as a substrate. The results correspond with those from endogenous and exogenous arachidonic acid. Aspirin affected the 6-keto-PGF\(_{1\alpha}\) release in a dose-dependent manner. This effect of aspirin was more effective in males than in females.

Effect of aspirin on PG\(_I_2\) production with addition of PGH\(_2\) used as a substrate

Table 1 shows the effect of aspirin on the PG\(_I_2\) production from exogenous PGH\(_2\). When arachidonic acid was used as the substrate, aspirin at a dose 50 mg/kg com-

pletely inhibited the PGI₂ production of rat aorta in both sexes. However, when PGH₂ was added as the substrate, aspirin had no influence on the PGI₂ production.

**Effect of aspirin in vitro**

Figure 4 shows that the PGI₂ production is inhibited by aspirin in vitro. In male rats, aspirin inhibited the PGI₂ production at 4.0 μg/ml, 61.0±16.7%; at 6.0 μg/ml, 32.6±13.7%; and at 10.0 μg/ml, 19.4±10.5%. In female rats, aspirin at 4.0 μg/ml did not inhibit the PGI₂ production, and aspirin at 6.0 μg/ml inhibited the PGI₂ production (56.8±15.0%). There was a sex difference in the effect of aspirin at 4.0, 6.0 and 10.0 μg/ml on the PGI₂ production in vitro.

**Influence of gonadectomy and sex hormones**

Table 2 shows the influence hormones and gonadectomy on PGI₂ production and the effect of aspirin.

1. **Change in PGI₂ production by gonadectomy:** In castrated male rats, aspirin showed a tendency to increase the PGI₂ production. The inhibitory effect of aspirin on the PGI₂ production was weaker in castrated male rats than in intact male rats. In ovariectomized female rats, the effect of aspirin was enhanced, and the amount of the produced PGI₂ in ovariectomized female rats was the same as that in intact male rats.

I: Intact; C: Castration; O: Ovariectomy; E: Estradiol (10 μg/kg); T: Testosterone (5.0 mg/kg); ————: Not tested; ASA, Aspirin. The values of the mean±S.D. (n=5) are given. **1**: Significant difference from the control value for each sex (P<0.05). **2**: Significant difference from the intact male control value (P<0.05).
ii) Change in PGI\(_2\) production by treatment with estradiol: To study the influence of sex hormones on PGI\(_2\) production, estradiol was administered. Doses of 10, 50 and 100 \(\mu\)g/kg were chosen. The influence of estradiol was similar among these three doses.

In the intact and castrated male rats treated with estradiol, the PGI\(_2\) production tended to increase. In the castrated male rats treated with estradiol, aspirin did not decrease the PGI\(_2\) production, but in the intact male rats with estradiol, aspirin showed a tendency to decrease the PGI\(_2\) production. In the intact and ovariectomized female rats treated with estradiol, the PGI\(_2\) production tended to increase, and the effect of aspirin was reduced.

iii) Change in PGI\(_2\) production by treatment with testosterone: To study the influence of testosterone on PGI\(_2\) production, rats were administered with testosterone (2.0, 5.0 and 10.0 mg/kg). The influence of testosterone was similar at 5.0 and 10.0 mg/kg, but it was weaker at 2.0 mg/kg.

In the intact male rats treated with testosterone, the effect of aspirin on the PGI\(_2\) production was similar to that in intact male rats. However, in the castrated male rats with testosterone, aspirin did not significantly decrease the PGI\(_2\) production. In the intact and ovariectomized female rats treated with testosterone, the effect of aspirin on the PGI\(_2\) production was enhanced and similar to that in intact male rats.

Interaction of aspirin with sex hormones in vitro

Interaction of aspirin with sex hormones was examined in vitro. It is shown that testosterone and estradiol did not influence the effect of aspirin directly.

Discussion

It is known that PGI\(_2\) is the main product in rat aorta and an important material in thrombosis. Some investigators have studied the PGI\(_2\) production in rat aorta. Pomerantz et al. (15) reported the sex hormonal modification of 6-keto-PGF\(_{1\alpha}\) release by intact and gonadectomized rats. Their results showed that more 6-keto-PGF\(_{1\alpha}\) was released by male rat aorta than by female rat aorta, estradiol decreased 6-keto-PGF\(_{1\alpha}\), and testosterone had no influence on 6-keto-PGF\(_{1\alpha}\) release by rat aorta. On the other hand, Chang et al. and Nakao et al. (8–10) reported that estradiol increased the PGI\(_2\) production in rat aorta, and testosterone decreased the PGI\(_2\) production in the cultured smooth muscle cells of rat aorta. These two conclusions contradicted each other. However, sex hormones must have some influence on the PGI\(_2\) production in rat aorta. In this study, the effect of aspirin on the PGI\(_2\) production of rat aorta was examined in intact, gonadectomized and sex hormone treated rats.

In intact rats, there was no significant sex difference in the PGI\(_2\) production in rat aorta when endogenous and exogenous arachidonic acid were used as substrates, but the PGI\(_2\) production in females was slightly more than in males. Aspirin decreased the PGI\(_2\) production dose-dependently, and the effect was more pronounced in males than in females.

Neither the significant sex difference nor the inhibitory effect of aspirin on PGI\(_2\) production was found in control rat aorta added with PGH\(_2\) as a substrate. These results show that aspirin does not affect the PGI\(_2\) synthesis process from PGH\(_2\). The site for the effect of aspirin seems to be in the course of the conversion of arachidonic acid to PGH\(_2\).

It is doubtful that a difference of the pharmacokinetics of aspirin causes the sex difference in PGI\(_2\) production. After 20 or 50 mg/kg of aspirin was administered to male and female rats, there was no sex difference in the maximum serum concentration, the time of the maximum serum concentration and the AUC of salicylic acid.

On the other hand, when the effect of aspirin was examined in vitro, aspirin significantly inhibited the PGI\(_2\) production at a lower concentration in male rats, but in female rats, high concentrations of aspirin were necessary to inhibit the PGI\(_2\) production. A significant sex difference was found in the effect of aspirin on PGI\(_2\) production. Aspirin affected the PGI\(_2\) production not only in vivo but also in vitro. Therefore, it is suggested that the sex difference in the effect of aspirin...
is not due to a process involving the pharmacokinetics of aspirin, but is a process involving the PG\(_1\) production.

In sex hormone treated rats, estradiol tended to increase the PG\(_1\) production in rat aorta, but testosterone tended to decrease it. In the male rats treated with estradiol, the effect of aspirin was weaker in castrated rats than in intact rats. It seems that in intact rats, endogenous testosterone may influence the action of exogenous estradiol in the process of PG\(_1\) production. Accordingly, it seems that aspirin strongly inhibited the PG\(_1\) production in the intact male rats treated with estradiol. Estradiol tended to increase the PG\(_1\) production and suppress the effect of aspirin in intact and ovariectomized female rats. Moreover, it was proven by Chang et al. (8) that estradiol stimulated cyclooxygenase in the cultured smooth muscle of rat aorta. Their results agree with the results of this report. It is suggested from the results in this study that the low concentration of estradiol (10 \(\mu\)g/kg) must have affected the process of PG\(_1\) production and reduced the effect of aspirin.

In the male rats treated with testosterone, the PG\(_1\) production tended to decrease, but the effect of aspirin was different between castrated rats and intact rats. Castration weakened the effect of aspirin on the process of PG\(_1\) production. So, it is suggested that endogenous testosterone plays an important role in the regulatory system for PG\(_1\) production. Nakao et al. (10) also reported that testosterone suppressed the PG\(_1\) production in cultured smooth muscle cells of rat aorta. This effect of testosterone in contrary to that of estradiol, and these two sex hormones must regulate the PG\(_1\) production in the body.

There is a possibility that aspirin may interact with sex hormones directly, but in vitro, the effect of aspirin on the PG\(_1\) production did not differ significantly in the presence or absence of hormone. So, it seems that sex hormones do not directly influence the effect of aspirin on the PG\(_1\) production.

The inhibitory effect of aspirin on the PG\(_1\) production was enhanced by testosterone treatment, but weakened by estradiol treatment. In female rats, it is likely that the capacity for PG\(_1\) production is latentely elevated by estradiol and the effect of aspirin consequently weakened. However, in male rats, it is likely that the capacity for PG\(_1\) production is reduced or not influenced by testosterone, and the effect of aspirin is strongly enhanced. It has not yet been reported whether testosterone suppresses cyclooxygenase.

These results suggest that the sex difference in the effect of aspirin is regulated by sex hormones. This must be one of the main reasons that the effect of aspirin on the PG\(_1\) production in rat aorta is stronger in males than in females. Further studies on the enzyme level are to be carried out by the authors.
