ON THE MONOID GENERATED BY A LUCAS SEQUENCE
CLEMENS HEUBERGER AND STEPHAN WAGNER

Abstract. A Lucas sequence is a sequence of the general form $v_n = (\phi^n - \overline{\phi}^n)/(\phi - \overline{\phi})$, where $\phi$ and $\overline{\phi}$ are real algebraic integers such that $\phi + \overline{\phi}$ and $\phi\overline{\phi}$ are both rational. Famous examples include the Fibonacci numbers, the Pell numbers, and the Mersenne numbers. We study the monoid that is generated by such a sequence; as it turns out, it is almost freely generated. We provide an asymptotic formula for the number of positive integers $\leq x$ in this monoid, and also prove Erdős-Kac type theorems for the distribution of the number of factors, with and without multiplicity. While the limiting distribution is Gaussian if only distinct factors are counted, this is no longer the case when multiplicities are taken into account.

1. Introduction

Let $\phi$ and $\overline{\phi}$ be real algebraic integers such that $\phi + \overline{\phi}$ and $\phi\overline{\phi}$ are fixed non-zero coprime rational integers with $\phi > |\overline{\phi}|$. The Lucas numbers associated with $(\phi, \overline{\phi})$ are

$$v_n = v_n(\phi, \overline{\phi}) = \frac{\phi^n - \overline{\phi}^n}{\phi - \overline{\phi}}, \quad n = 1, 2, 3, \ldots.$$ 

All these numbers are positive integers, and the sequence is strictly increasing for $n \geq 2$. Famous examples include the Fibonacci numbers ($\phi = \frac{1+\sqrt{5}}{2}$, $\overline{\phi} = \frac{1-\sqrt{5}}{2}$), the Pell numbers ($\phi = 1 + \sqrt{2}$, $\overline{\phi} = 1 - \sqrt{2}$), and the Mersenne numbers ($\phi = 2$, $\overline{\phi} = 1$). The multiplicative group generated by such a sequence was studied in a recent paper by Luca et al. [15]; by definition, it consists of all quotients of products of elements of the sequence. In [15], a near-asymptotic formula for the number of integers in this group was given (in the specific case of the Fibonacci sequence, but the method is more general). This continued earlier work of Luca and Porubský [16], who considered the multiplicative group generated by a Lehmer sequence and showed that the number of integers below $x$ in the resulting group is $O(x/(\log x)^{\delta})$ for any positive number $\delta$.

As it turns out, the group that is generated by a Lucas sequence is almost a free group; this is due to the existence of primitive divisors. A prime number $p$ is a primitive divisor of $v_n(\phi, \overline{\phi})$ if $p$ divides $v_n$ but does not divide $v_1 \ldots v_{n-1}$. It is a classical result, due to Carmichael, that almost all elements of a Lucas sequence have primitive divisors:

**Theorem** (Carmichael [3 Theorem XXIII]). If $n \notin \{1, 2, 6, 12\}$, then $v_n(\phi, \overline{\phi})$ has a primitive divisor.

See also Bilu, Hanrot and Voutier [2]. Note the slightly different definition in [2] which does not allow a primitive divisor to divide \((\phi - \overline{\phi})^2\).

Let now
\[
F = \{ v_n(\phi, \overline{\phi}) \mid v_n(\phi, \overline{\phi}) \text{ has a primitive divisor} \}.
\]

By Carmichael’s theorem, \(F\) includes all but finitely many \(v_n\). We let \(F_0\) be the set of all \(v_n(\phi, \overline{\phi})\) with \(n \leq 12\) that have a primitive divisor, so that
\[
F = F_0 \cup \{ v_n(\phi, \overline{\phi}) \mid n \geq 13 \}.
\]

For example, in the case of the golden ratio \(\phi = (1 + \sqrt{5})/2, \overline{\phi} = (1 - \sqrt{5})/2,\) we have
\[
F_0 = \{ 2, 3, 5, 13, 21, 34, 55, 89 \}
\]
and
\[
F = \{ 2, 3, 5, 13, 21, 34, 55, 89, 233, 377, \ldots \},
\]
which are all the Fibonacci numbers except 1, 8 and 144.

Instead of the full group that was studied in [16] and [15], we consider the free monoid
\[
M(F) = \{ m_1 \ldots m_k \mid k \geq 0, m_j \in F \}
\]
generated by \(F\). It is an easy consequence of the existence of primitive divisors that every element of \(M(F)\) has a unique factorisation into elements of \(F\): If an element has two factorisations, consider a primitive divisor of the largest element of \(F\) occurring in either of those factorisations. This prime number has to occur in all factorisations, so the largest element of \(F\) occurring in any factorisation of the element is fixed. The result follows by induction.

To give a concrete example, the elements of our monoid are
\[
M(F) = \{ 1, 2, 3, 4, 5, 6, 8, 9, 10, 12, 13, 15, 16, 18, 20, 21, 24, 25, 26, 27, 30, 32, 34, \ldots \}
\]
in the case of the Fibonacci numbers (cf. [17], A065108).

Our first result describes the asymptotic number of elements in \(M(F)\) up to a given bound, paralleling the aforementioned result of [15], but even being more precise. All constants, implicit constants in \(O\)-terms and the Vinogradov notation will depend on \(\phi\) and \(\overline{\phi}\).

**Theorem 1.** We have
\[
| M(F) \cap [1, x] | = k_0 (\log x)^{k_1} \exp \left( \pi \sqrt{ \frac{2 \log x}{3 \log \phi} } \left( 1 + O \left( \frac{1}{(\log x)^{1/10}} \right) \right) \right)
\]
for \(x \to \infty\) and suitable constants \(k_0\) and \(k_1\). Specifically,
\[
k_1 = \frac{|F_0| - 13}{2} + \frac{\log(\phi - \overline{\phi})}{2 \log \phi}.
\]

**Remark.** An explicit expression for \(k_0\) can be given as well, but it is rather unwieldy.

Since all elements of \(M(F)\) have a unique factorisation into elements of \(F\), it makes sense to consider the number of factors in this factorisation and to study its distribution. The celebrated Erdős-Kac theorem [7] states that the number of distinct prime factors of a randomly chosen integer in \([1, x]\) is asymptotically normally distributed. The same is true if primes are counted with multiplicity. We refer to Chapter 12 of [6] for a detailed discussion of the Erdős-Kac theorem and its generalisations.

Our aim is to prove similar statements for the monoid \(M(F)\). Let \(n\) be an element of this monoid. By \(\omega_F(n)\) and \(\Omega_F(n)\), we denote the number of factors in the factorisation of \(n\) into elements of \(F\) without and with multiplicities, respectively.

We first prove asymptotic normality for \(\omega_F\), in complete analogy with the Erdős-Kac theorem:
Theorem 2. Let $N$ be a uniformly random positive integer in $\mathcal{M}(\mathcal{F}) \cap [1, x]$ and let

\[
\begin{aligned}
& a_1 = \frac{1}{\pi} \sqrt{\frac{6}{\log \phi}}, \\
& a_2 = \frac{\pi^2 - 6}{2\pi^3} \sqrt{\frac{6}{\log \phi}}.
\end{aligned}
\]

The random variable $\omega_\mathcal{F}(N)$ is asymptotically normal: we have

\[
\lim_{x \to \infty} \Pr\left( \frac{\omega_\mathcal{F}(N) - a_1 \log^{1/2} x}{\sqrt{a_2 \log^{1/4} x}} \leq z \right) = \frac{1}{\sqrt{2\pi}} \int_0^z e^{-y^2/2} dy.
\]

However, the situation changes when multiplicities are taken into account: unlike the arithmetic function $\Omega$, which counts all prime factors with multiplicity, $\Omega_\mathcal{F}$ is not normally distributed. Its limiting distribution can rather be described as a sum of shifted exponential random variables, as the following theorem shows:

Theorem 3. Let $N$ be a uniformly random positive integer in $\mathcal{M}(\mathcal{F}) \cap [1, x]$, let $a_1$ be the same constant as in the previous theorem and, with $\gamma$ denoting the Euler-Mascheroni constant,

\[
\begin{aligned}
& b_1 = \frac{\sqrt{6 \log \phi}}{\pi} \left(2 \gamma - \log \left(\frac{\pi^2 \log \phi}{6}\right) \right) + \sum_{m \in \mathcal{F}_0} \frac{1}{\log m} + \frac{1}{\log v_{13}(\phi, \phi)} \\
& \quad \quad + \sum_{k \geq 1} \left(\frac{1}{\log v_{k+13}(\phi, \phi)} - \frac{1}{k \log \phi}\right), \\
& b_2 = \frac{\sqrt{6 \log \phi}}{\pi}.
\end{aligned}
\]

The random variable $\Omega_\mathcal{F}(N)$, suitably normalised, converges weakly to a sum of shifted exponentially distributed random variables:

\[
\begin{aligned}
\frac{\Omega_\mathcal{F}(N) - a_1 \log^{1/2} x \log \log x - b_1 \log^{1/2} x}{b_2 \log^{1/2} x} \xrightarrow{d} \sum_{m \in \mathcal{F}} \left(X_m - \frac{1}{\log m}\right),
\end{aligned}
\]

where $X_m \sim \text{Exp}(\log m)$.

This is somewhat reminiscent of the situation for the number of parts in a partition: Goh and Schmutz [12] proved that the number of distinct parts in a random partition of a large integer $n$ is asymptotically normally distributed, while the total number of parts with multiplicity was shown by Erdős and Lehner [8] to follow a Gumbel distribution (which can also be represented as a sum of shifted exponential random variables). Indeed, our results are multiplicative analogues in a certain sense, since products turn into sums upon applying the logarithm, and $\log v_n(\phi, \phi) \sim (\log \phi)n$.

We remark that the monoid $\mathcal{M}(\mathcal{F})$ fits the definition of an arithmetical semigroup as studied in abstract analytic number theory (see [14] for a general reference on the subject). However, as Theorem 1 shows, it is very sparse, so it does not satisfy the growth conditions that are typically imposed in this context. For arithmetical semigroups that satisfy such growth conditions, Erdős-Kac type theorems are known as well, see [14, Theorem 7.6.5] and [19, Theorem 3.1].

2. Proof of Theorems 1 and 2

For real $u$ in a neighbourhood of 1, we consider the Dirichlet generating function $d(z, u)$ that is defined as follows:

\[
d(z, u) := \sum_{n \in \mathcal{M}(\mathcal{F})} \frac{u^{\omega_\mathcal{F}(n)}}{n^z},
\]
for all complex \( z \) for which the series converges (Lemma 2 will provide detailed information on convergence). Within the region of convergence, we have the product representation

\[
(1) \quad d(z, u) = \prod_{m \in \mathcal{F}} (1 + um^{-z} + um^{-2z} + \cdots) = \prod_{m \in \mathcal{F}} \left( 1 + \frac{um^{-z}}{1 - m^{-z}} \right).
\]

Set \( h(n) = u^{\omega_F(n)} \) if \( n \in \mathcal{M}(\mathcal{F}) \) and \( h(n) = 0 \) otherwise. We use the Mellin–Perron summation formula in the version

\[
(2) \quad \sum_{1 \leq n \leq x} h(n) \left( 1 - \frac{n}{x} \right) = \frac{1}{2\pi i} \int_{r-i\infty}^{r+i\infty} \left( \sum_{n=1}^{\infty} \frac{h(n)}{n^s} \right) x^{-s} \frac{dz}{z(z+1)},
\]

for \( x > 0 \) where \( r \) is in the half-plane of absolute convergence of the Dirichlet series \( \sum_{n=1}^{\infty} \frac{h(n)}{n^s} \) (see e.g. [1, Chapter 13] or [10, Theorem 2.1]). Thus

\[
(3) \quad I_{\omega_F}(x, u) := \sum_{n \in \mathcal{M}(\mathcal{F}), n \leq x} u^{\omega_F(n)} \left( 1 - \frac{n}{x} \right) = \frac{1}{2\pi i} \int_{r-i\infty}^{r+i\infty} d(z, u) z^{x-1} dz.
\]

We will use a saddle-point approach to evaluate this integral. As a first step, we establish an estimate for \( d(z, u) \) for \( z = r + it \), \( r \to 0^+ \) and small \( t \). We start with an auxiliary lemma for another Dirichlet generating series.

**Lemma 1.** Let \( v \) be a complex number such that \( |v| < v_0 \), where

\[
(4) \quad v_0 := \min \left\{ \log m \mid m \in \mathcal{F}_0 \text{ or } m = \frac{\phi_{13}}{\phi - \phi} \right\}
\]

and let \( \Lambda(s, v) \) be given by the Dirichlet series

\[
\Lambda(s, v) := \sum_{m \in \mathcal{F}} \frac{1}{(\log m - v)^s},
\]

which converges for \( \Re s > 1 \). The function \( \Lambda(s, v) \) can be analytically continued to a meromorphic function in \( s \) with a single simple pole at \( s = 1 \) with residue \( 1/\log \phi \).

We have

\[
(5) \quad \Lambda(0, v) = |\mathcal{F}_0| - \frac{25}{2} + \frac{\log(\phi - \phi)}{\log \phi} + v,
\]

\[
\left. \frac{\partial \Lambda(s, v)}{\partial s} \right|_{s=0} = -\sum_{m \in \mathcal{F}} \left( \log \left( 1 - \frac{v}{\log m} \right) + \frac{v}{\log m} \right) + \kappa_1 v + \kappa_2,
\]

where \( \kappa_1 \) and \( \kappa_2 \) are constants, and \( \kappa_1 \) is given by

\[
(6) \quad \kappa_1 := \gamma - \log \log \phi + \sum_{m \in \mathcal{F}_0} \frac{1}{\log m} + \frac{1}{\log v_{13}(\phi, \phi)} + \sum_{k \geq 1} \left( \frac{1}{\log v_{k+13}(\phi, \phi)} - \frac{1}{k \log \phi} \right).
\]

Finally,

\[
\Lambda(s, v) = O(s^2)
\]

for \(-3/2 \leq \Re s \leq 2\) with \( |s - 1| \geq 1 \) and \( |s| \geq 1 \).
Proof. Let

\[ \Lambda_0(s, v) := \sum_{m \in \mathcal{F}_0} \frac{1}{(\log m - v)^s}, \]

\[ \Lambda_1(s, v) := \sum_{j \geq 13} \left( \left( \frac{\phi^j - \overline{\phi}^j}{\phi - \overline{\phi}} - v \right)^{-s} - \left( \frac{\phi^j - \overline{\phi}^j}{\phi - \overline{\phi}} - \overline{v} \right)^{-s} \right), \]

\[ \alpha(v) := 13 - \frac{\log(\phi - \overline{\phi}) + v}{\log \phi}. \]

Note that our choice of \( v_0 \) guarantees that each summand of \( \Lambda \), \( \Lambda_0 \) and \( \Lambda_1 \) is well-defined and that \( \Re \alpha(v) > 0 \).

Thus

\[ \Lambda(s, v) = \Lambda_0(s, v) + \sum_{j \geq 13} \frac{1}{(j \log \phi - \log(\phi - \overline{\phi}) - v)^s} + \Lambda_1(s, v) \]

\[ = \frac{1}{\log^s \phi} \zeta(s, \alpha(v)) + \Lambda_0(s, v) + \Lambda_1(s, v), \]

where \( \zeta(s, \beta) = \sum_{k \geq 0} (k + \beta)^s \) denotes the Hurwitz zeta function (the series converges for \( \Re s > 1 \) if \( \beta \not\in \{0, -1, -2, \ldots\} \), and it can be analytically continued), cf. [5, 25.11.1].

The function \( \Lambda_0(s, v) \) is obviously an entire function, and it is bounded for \( \Re s \geq -3/2 \).

Estimating the difference occurring in \( \Lambda_1(s, v) \), we see that

\[ \Lambda_1(s, v) = O \left( \sum_{j \geq 13} \frac{s(|\phi|^j/\phi)^j}{(j \log \phi - \log(\phi - \overline{\phi}) - v)^s} \right). \]

Thus \( \Lambda_1(s, v) \) is an entire function, and we have the estimate \( \Lambda_1(s, v) = O(s) \) for \( \Re s \geq -3/2 \).

Moreover, \( \zeta(s, \alpha) \) is a meromorphic function with a single simple pole at \( s = 1 \) with residue 1, and by [20, §13.51], we have

\[ \zeta(s, \alpha(v)) = O(s^2) \]

in the given area, which proves the desired asymptotic estimate. It remains to determine the values of the function and its derivative at \( s = 0 \).

Observe first that \( \Lambda_0(0, v) = |\mathcal{F}_0| \) and \( \Lambda_1(0, v) = 0 \). Moreover, we have

\[ \zeta(0, \alpha(v)) = \frac{1}{2} - \alpha(v), \]

cf. [5, 25.11.13]. Now we consider the first derivative. \( \Lambda_0 \) and \( \Lambda_1 \) are simply differentiated term by term:

\[ \frac{\partial \Lambda_0(s, v)}{\partial s} \bigg|_{s=0} = - \sum_{m \in \mathcal{F}_0} \log(\log m - v) - \sum_{m \in \mathcal{F}_0} \left( \log \log m + \log \left( 1 - \frac{v}{\log m} \right) \right) \]

and

\[ \frac{\partial \Lambda_1(s, v)}{\partial s} \bigg|_{s=0} = - \sum_{j \geq 13} \left( \log \left( \frac{\phi^j - \overline{\phi}^j}{\phi - \overline{\phi}} - v \right) - \log \left( \frac{\phi^j - \overline{\phi}^j}{\phi - \overline{\phi}} - \overline{v} \right) \right) \]

\[ = - \sum_{j \geq 13} \left( \log \left( \log v_j(\phi, \overline{\phi}) - v \right) - \log \log \phi - \log(j - 13 + \alpha(v)) \right), \]

Finally, it is well known (see [5, 25.11.18]) that

\[ \frac{\partial \zeta(s, \alpha)}{\partial s} \bigg|_{s=0} = \log \Gamma(\alpha) - \frac{1}{2} \log(2\pi), \]
The infinite sum can be combined with the sum in the derivative of \( \text{Li} \) where asymptotic estimates selecting the linear terms gives the stated formula for \( \kappa_1 \).

Apart from the first sum, all terms are indeed either constant or linear in \( v \). Collecting the linear terms gives the stated formula for \( \kappa_1 \), completing our proof. \( \square \)

**Lemma 2.** Let \( r > 0 \), \( z = r + it \) with \( |t| \leq r^{7/5} \), and \( |1 - u| < 1 \).

The Dirichlet series \( d(z, u) \) converges absolutely for \( \Re z > 0 \), and we have the asymptotic estimates

\[
d(z, u) = d(r, u) \exp \left( -\frac{ia(u)t}{r^2} - \frac{a(u)t^2}{r^4} + O(r^{1/5}) \right),
\]

(7)

\[
d(r, u) = \exp \left( \frac{a(u)}{r} + b \log r + c(u) + O(r) \right)
\]

for \( r \to 0^+ \) and

\[
a(u) = \frac{\pi^2/6 - \text{Li}_2(1 - u)}{\log \phi},
\]

where \( \text{Li} \) denotes the polylogarithm,

\[
b = -|\mathcal{F}_0| + \frac{25}{2} - \frac{\log(\phi - \overline{\phi})}{\log \phi}.
\]
and \( c(u) \) is a function which is analytic in a complex neighbourhood of \( 1 \). The estimates are uniform in \( u \) on compact sets.

**Proof.** Let

\[
g(z, u) := \sum_{m \in \mathcal{F}} \log \left( 1 + \frac{um^{-z}}{1 - m^{-z}} \right),
\]

which implies \( d(z, u) = \exp(g(z, u)) \) by \([1] \). For \( \Re z > 0 \) and fixed \( u \), we have

\[
\log \left( 1 + \frac{um^{-z}}{1 - m^{-z}} \right) \sim um^{-z}
\]

for \( m \to \infty \). Since the elements of \( \mathcal{F} \) follow the asymptotic formula

\[
v_\ell = v_\ell(\phi, \overline{\phi}) \sim \phi^\ell \phi^{-\ell},
\]

the series \( g(z, u) \) converges absolutely.

We rewrite \( g(z, u) \) as

\[
g(z, u) = \sum_{m \in \mathcal{F}} \log \left( 1 + \frac{ue^{-z} \log m}{1 - e^{-z} \log m} \right) = \sum_{m \in \mathcal{F}} f(z \log m, u)
\]

for \( f(z, u) = \log \left( 1 + \frac{ue^{-z}}{1 - e^{-z}} \right) \).

For \( \Re s > 1 \), we consider the Mellin transform \( g^*(s, u) \) of the harmonic sum \( g(z, u) \) and obtain

\[
g^*(s, u) = f^*(s, u) \sum_{m \in \mathcal{F}} \frac{1}{(\log m)^s} = f^*(s, u) \Lambda(s, 0)
\]

with \( \Lambda \) as defined in Lemma \([1] \).

We compute \( f^*(s, u) \). We have

\[
f(z, u) = \log \left( 1 + \frac{ue^{-z}}{1 - e^{-z}} \right) = \log(1 - (1 - u)e^{-z}) - \log(1 - e^{-z})
\]

\[
= \sum_{j=1}^{\infty} \frac{1 - (1 - u)^j}{j} e^{-zj}.
\]

Thus the Mellin transform is

\[
f^*(s, u) = \left( \sum_{j \geq 1} \frac{1 - (1 - u)^j}{j^{1+s}} \right) \Gamma(s) = (\zeta(s + 1) - \text{Li}_{s+1}(1 - u)) \Gamma(s).
\]

Note that the polylogarithm \( \text{Li}_{s+1}(1 - u) \) is an entire function in \( s \) for \( |1 - u| < 1 \).

We conclude that

\[
g^*(s, u) = (\zeta(s + 1) - \text{Li}_{s+1}(1 - u)) \Gamma(s) \Lambda(s, 0).
\]

This is a meromorphic function in \( s \) with a simple pole at \( s = 1 \), a double pole at \( s = 0 \) and at most simple poles when \( s \) is a negative integer. When \( s \) runs along vertical lines, \( g^*(s, u)z^{-s} \) decreases exponentially for \( |\arg(z)| < \pi/4 \) due to the factor \( \Gamma(s) \).

We have

\[
\text{Res}_{s=1} g^*(s, u) = \frac{\pi^2/6 - \text{Li}_2(1 - u)}{\log \phi} =: a(u).
\]

In addition, we have the singular expansion

\[
g^*(s, u) = -\frac{b}{s^2} + \frac{c(u)}{s} + O(1)
\]

around 0, where \( b = -\Lambda(0, 0) \) and

\[
c(u) = \Lambda(0, 0) \log u + \frac{\partial \Lambda(s, 0)}{\partial s} \bigg|_{s=0}
\]
Lemma 3. Let $r > 0$ and $z = r + it$ with $|t| \geq r^{7/5}$. Then
\[ \log d(r, u) - \Re \log d(z, u) \gg \frac{1}{r^{1/5}} \]
for $u \in (1/2, 3/2)$ and $r \to 0^+$ unless there is a non-zero integer $k$ such that $|t - 2k\pi/\log \phi| < r^{3/4}$.
Proof. Using the function $g(z, u)$ from the beginning of the proof of Lemma 2, we have

$$g(z, u) = \sum_{m \in F} \log \left( \frac{1 - (1 - u)m^{-z}}{1 - m^{-z}} \right) = \sum_{m \in F} \sum_{k = 1} \frac{1 - (1 - u)^k}{k} m^{-kz}$$

$$= \sum_{m \in F} \sum_{k = 1} \frac{1 - (1 - u)^k}{k} m^{-kr} (\cos(kt \log m) - i \sin(kt \log m)).$$

This implies that

$$\log d(r, u) - \Re \log d(z, u) = \sum_{m \in F} \sum_{k = 1} \frac{1 - (1 - u)^k}{k} m^{-kr} (1 - \cos(kt \log m)).$$

Obviously, all summands are non-negative, so we take the first summand as a lower bound and obtain

$$\log d(r, u) - \Re \log d(z, u) \geq u \sum_{m \in F} m^{-r} (1 - \cos(t \log m)).$$

For $\ell \geq 13$, we use the estimate $v_\ell = \frac{e^{\ell \log \phi} - 1}{\phi - \phi} \leq K_0 \phi^\ell$ for a suitable $K_0 > 1$. In the following, we assume that $r < 1$. If $13 \leq \ell \leq 1/r$, then

$$v_\ell \leq K_0 \phi \leq K_0 \phi.$$

Thus restricting the sum to those $\ell$ and the corresponding $v_\ell$ yields

$$\log d(r, u) - \Re \log d(z, u) \gg \sum_{13 \leq \ell < 1/r} (1 - \cos(t \log v_\ell)).$$

We first consider the case that $|t| \leq r / \log \phi$. In this case, we have

$$|t| \log v_\ell \leq \frac{r}{\log \phi} (\ell \log \phi + \log K_0) \leq 1 + \frac{r \log K_0}{\log \phi} < \frac{\pi}{2}$$

for sufficiently small $r$. Thus we may use the inequality $1 - \cos \theta = 2 \sin^2(\theta/2) \geq (4/\pi^2)\theta^2$ (which is a consequence of concavity of $\sin$) to obtain

$$\log d(r, u) - \Re \log d(z, u) \gg \sum_{13 \leq \ell \leq 1/r} t^2 \log^2 v_\ell \gg t^2 \sum_{13 \leq \ell \leq 1/r} \ell^2 \gg \frac{t^2}{r^{1/5}} \geq \frac{1}{r^{1/5}}.$$}

Next, we consider the case that $r / \log \phi \leq |t| \leq r^{1/5}$. Here we omit all summands with $\ell > 1/(|t| \log \phi)$ in (12) and obtain

$$\log d(r, u) - \Re \log d(z, u) \gg \sum_{13 \leq \ell \leq 1/(|t| \log \phi)} (1 - \cos(t \log v_\ell))$$

$$\gg t^2 \sum_{13 \leq \ell \leq 1/(|t| \log \phi)} \log^2 v_\ell \gg \frac{t^2}{|t|^3} \frac{1}{|t|} \geq \frac{1}{r^{1/5}}$$

by the same arguments as above.
Finally, we turn to the case that \(|t| > r^{1/5}\). We estimate the sum of the cosines by a geometric sum:

\[
\sum_{13 \leq t \leq 1/r} \cos(t \log \nu_t) = \Re \sum_{13 \leq t \leq 1/r} \exp(it \log \nu_t)
\]

\[
\leq \left| \sum_{13 \leq t \leq 1/r} \exp \left( it \left( t \log \phi - \log(\phi - \overline{\phi}) + O \left( \left( \frac{\overline{\phi}}{\phi} \right)^5 \right) \right) \right) \right|
\]

\[
= \left| \sum_{13 \leq t \leq 1/r} \left( \exp(it \log \phi) + O \left( \left( \frac{\overline{\phi}}{\phi} \right)^5 \right) \right) \right|
\]

\[
\leq \frac{2}{\exp(it \log \phi) - 1} + O(1).
\]

Choose an integer \(k\) such that \(|t \log \phi - 2k\pi|\) is minimal. Then \(|t \log \phi - 2k\pi| \geq r^{3/4} \log \phi\) in view of the assumption made on \(t\) in the statement of the lemma (if \(k \neq 0\)) and because \(|t| > r^{1/5}\) (if \(k = 0\)). We therefore have \(|\exp(it \log \phi) - 1| \gg r^{3/4}\).

Combining this with (12), we conclude that

\[
\log d(r, u) - \Re \log d(z, u) \gg \frac{1}{r} - \frac{1}{r^{3/4}} \gg \frac{1}{r},
\]

as required. \(\square\)

We are now able to estimate the integral in (9), choosing \(r\) appropriately.

**Lemma 4.** Let \(u \in (1/2, 3/2)\) and \(r = \sqrt{a(u)/\log x}\). Then

\[
\left(13\right) \quad \frac{1}{2\pi i} \int_{r-i\infty}^{r+i\infty} \frac{d(z, u) x^z}{z(z + 1)} \frac{dz}{dz} = \frac{d(r, u)x^r}{2\pi \sqrt{a(u)}} \left(1 + O(r^{1/5})\right)
\]

for \(x \to \infty\).

**Proof.** We first compute the integral over

\[M_0 = \{r + it \mid |t| \leq r^{7/5}\}.\]

For \(z \in M_0\), we have

\[
\frac{1}{z} = \frac{1}{r} \left(1 + O \left( \frac{t}{r} \right) \right) = \frac{1}{r} \left(1 + O(r^{2/5})\right), \quad \frac{1}{z + 1} = 1 + O(r).
\]

By Lemma 2, we have

\[
\frac{d(z, u) x^z}{z(z + 1)} = \frac{d(r, u)x^r}{r} \exp \left( - \frac{ia(u)t}{r^2} - \frac{a(u)t^2}{r^3} + it \log x + O(r^{1/5}) \right).
\]

The value \(r = \sqrt{a(u)/\log x}\) has been chosen in such a way that the linear terms vanish. Thus we get

\[
\frac{d(z, u)x^z}{z(z + 1)} = \frac{d(r, u)x^r(1 + O(r^{1/5}))}{r} \exp \left( - \frac{a(u)t^2}{r^4} \right).
\]

We have

\[
\frac{1}{2\pi i} \int_{z \in M_0} \frac{d(z, u)x^z}{z(z + 1)} \frac{dz}{dz} = \frac{d(r, u)x^r(1 + O(r^{1/5}))}{2\pi r} \int_{-r^{7/5}}^{r^{7/5}} \exp \left( - \frac{a(u)t^2}{r^3} \right) \frac{dt}{dt}
\]

\[
= \frac{d(r, u)x^r(1 + O(r^{1/5}))}{2\pi r} \int_{-\infty}^{\infty} \exp \left( - \frac{a(u)t^2}{r^3} \right) \frac{dt}{dt}
\]
because adding the tails induces an exponentially small error (note that $a(u) > 0$).

Computing the integral yields

$$\frac{1}{2\pi i} \int_{z \in M_0} \frac{d(z, u)}{z(z + 1)} x^z \, dz = \frac{d(r, u)x^r}{2\pi} \frac{r^{1/2}}{\sqrt{a(u)}} (1 + O(r^{1/5})).$$

(14)

Next, we compute the integral over

$$M_1 = \{ r + it \in \mathbb{C} \mid \exists k \in \mathbb{Z} \setminus \{0\} : |t - 2k\pi/\log \phi| < r^{3/4} \}.$$ 

We use the trivial bound $|d(z, u)| \leq d(r, u)$, which follows from the definition of $d(z, u)$ as a Dirichlet series. Using the estimates $|z| \geq |3z|$ and $|z + 1| \geq |3z|$ yields

$$\left| \frac{1}{2\pi i} \int_{z \in M_1} \frac{d(z, u)}{z(z + 1)} x^z \, dz \right| \leq \frac{d(r, u)x^r}{2\pi} \sum_{k \in \mathbb{Z} \setminus \{0\}} \frac{2^{3/4}}{|2k\pi/\log \phi - r^{3/4}|^2} \ll \frac{d(r, u)x^r}{2\pi} r^{3/4}.$$ 

Thus this integral can be absorbed by the error term of (14).

Finally, we compute the integral over

$$M_2 := \{ r + it \in \mathbb{C} \setminus (M_0 \cup M_1) \}.$$ 

For $z \in M_2$, we have

$$|d(z, u)| \leq d(r, u) \exp\left( - \frac{K_1}{r^{1/5}} \right)$$

for a suitable positive constant $K_1$ by Lemma [3]. Thus

$$\left| \frac{1}{2\pi i} \int_{z \in M_2} \frac{d(z, u)}{z(z + 1)} x^z \, dz \right| \ll d(r, u)x^r \exp\left( - \frac{K_1}{r^{1/5}} \right) \int_{z \in M_2} \frac{1}{|z(z + 1)|} \, dz \ll d(r, u)x^r \exp\left( - \frac{K_1}{r^{1/5}} \right) \log \frac{1}{r^3}.$$ 

As this integral is also absorbed by the error term of (14), we get (13). □

In view of (13), Lemma [3] immediately gives us

$$I_{\omega \gamma}(x, u) = \sum_{n \in M(F), n \leq x} u_{\omega \gamma}(n) \left( 1 - \frac{n}{x} \right) \sim \frac{d(r, u)x^r}{2\pi} \frac{r^{1/2}}{\sqrt{a(u)}}.$$ 

However, we are actually interested in an expression for the sum without the additional factor $(1 - \frac{n}{x})$. This is achieved in the following lemma.

**Lemma 5.** We have

$$\sum_{n \in M(F), n \leq x} u_{\omega \gamma}(n) =$$

$$\frac{1}{2\sqrt{\pi}} \exp \left( 2\sqrt{a(u)} \sqrt{\log x} - \frac{2b + 1}{4} \log \log x + \frac{2b - 1}{4} \log a(u) + c(u) \right) \times \left( 1 + O\left( \frac{1}{(\log x)^{1/10}} \right) \right)$$

for $x \to \infty$ and $1/2 < u < 3/2$.

**Proof.** Trivially, the inequality

$$\frac{1}{\sqrt{\pi}} \int_{z \in M} \frac{d(z, u)}{z(z + 1)} x^z \, dz = \frac{d(r, u)x^r}{2\pi} \frac{r^{1/2}}{\sqrt{a(u)}} (1 + O(r^{1/5}))$$

(15)
holds for positive $u$. On the other hand, we also have
\[
\frac{I_{\omega,F}(x \log x, u)}{1 - \frac{1}{\log x}} = \frac{1}{1 - \frac{1}{\log x}} \sum_{n \in \mathcal{M}(F), n \leq x \log x} u^{\omega,F(n)} \left(1 - \frac{n}{x \log x}\right)
\]
(16)
\[
\geq \frac{1}{1 - \frac{1}{\log x}} \sum_{n \in \mathcal{M}(F), n \leq x} u^{\omega,F(n)} \left(1 - \frac{n}{x \log x}\right)
\]
for positive $u$ and $x > 1$.

Now we choose $r = \sqrt{a(u)/\log x}$ as in Lemma 4 and use (3) as well as Lemma 4 to obtain
\[
I_{\omega,F}(x, u) = \frac{d(r, u)x^{r/2}}{2 \sqrt{\pi a(u)}} (1 + O(r^{1/5})).
\]
Finally, the asymptotic formula (7) for $d(r, u)$ gives us
\[
I_{\omega,F}(x, u) = \frac{1}{2 \sqrt{\pi}} \exp\left(\frac{a(u)}{r} + b \log r + c(u) + r \log x + \frac{1}{2}(\log r - \log a(u))\right)
\times (1 + O(r^{1/5}))
\]
\[
= \frac{1}{2 \sqrt{\pi}} \exp\left(2 \sqrt{a(u)} \sqrt{\log x} - \frac{2b}{4} \log \log x + \frac{2b}{4} \log a(u) + c(u)\right)
\times (1 + O\left(\frac{1}{(\log x)^{1/10}}\right)).
\]
If we replace $x$ by $x \log x$ and divide by $1 - 1/\log x$, we obtain exactly the same asymptotic expansion, the difference being absorbed by the error term. Combining this with (15) and (16) yields the result. □

We are now able to prove Theorems 1 and 2.

**Proof of Theorem 1.** Setting $u = 1$ in Lemma 5 yields the result. □

**Proof of Theorem 2.** We consider the moment generating function
\[
\mathbb{E}(e^{\omega,F(N)t}) = \sum_{n \in \mathcal{M}(F), n \leq x} \frac{e^{\omega,F(n)t}}{\sum_{n \in \mathcal{M}(F), n \leq x} 1}.
\]
Lemma 5 yields
\[
\mathbb{E}(e^{\omega,F(N)t}) = \exp\left(2(\sqrt{a(t)} - \sqrt{a(1)}) \sqrt{\log x} + O(t)\right) \left(1 + O\left(\frac{1}{(\log x)^{1/10}}\right)\right)
\]
for $\log \frac{1}{2} < t < \log \frac{3}{2}$. We compute the Taylor expansion of $2(\sqrt{a(t)} - \sqrt{a(1)})$ around 0 as
\[
2(\sqrt{a(t)} - \sqrt{a(1)}) = a_1 t + \frac{a_2}{2} t^2 + O(t^3)
\]
for the constants $a_1$, $a_2$ given in the theorem. Thus the moment generating function of the renormalised random variable $Z = (\omega,F(N)) - a_1 \log^{1/2} x)/(\sqrt{a_2} \log^{1/4} x)$ is
\[
\mathbb{E}(e^{Zt}) = \exp\left(t^2 + O\left(\frac{t^3}{\log^{1/4} x}\right)\right) \left(1 + O\left(\frac{1}{(\log x)^{1/10}}\right)\right).
\]
For all real $t$, this moment generating function converges pointwise to the moment generating function $e^{t^2/2}$ of the standard normal distribution. By Curtiss’
3. Proof of Theorem 3: Counting with Multiplicities

Let $r > 0$ and consider the interval $U = U(r) = (\exp(-v_0 r/2), \exp(v_0 r/2))$, where $v_0$ has been defined in (4).

For $u \in U$ and $\Re z > r/2$, we study the Dirichlet generating function

$$D(z, u) = \sum_{n \in M(F)} \frac{u^{\Omega_F(n)}}{n^z},$$

which has a product representation

$$D(z, u) = \prod_{m \in F} \frac{1}{1 - um^{-z}}$$

for all such $z$ and $u$.

**Lemma 6.** Let $r > 0$, $|t| \leq r^{7/5}$ and $u \in U$. Then

$$D(r + it, u) = D(r, u) \exp\left(-\frac{i A t}{r} - \frac{A t^2}{r^2} + O(r^{1/5})\right),$$

for $A = \pi^2/(6 \log \phi)$, $B(v) = -\Lambda(0, v)$, and $C(v) = \frac{\partial \Lambda(s, v)}{\partial s} \Big|_{s=0}$ in a neighbourhood of the origin.

**Proof.** Let $\Re z > r/2$ and $v = (\log u)/z$. The assumption $u \in U$ implies that $|v| < rv_0/(2|z|) < v_0$.

We consider the sum

$$G(z, v) = -\sum_{m \in F} \log(1 - e^{vz} m^{-z}).$$

Expanding the logarithm yields

$$G(z, v) = \sum_{m \in F} \sum_{k \geq 1} \frac{e^{ks} m^{-kz}}{k} = \sum_{m \in F} \sum_{k \geq 1} \exp(-k \log m - v k z) \frac{1}{k}.$$ 

Its Mellin transform is

$$G^*(s, v) = \sum_{m \in F} \sum_{k \geq 1} \frac{1}{k^{1+s} (\log m - v)^s} \Gamma(s) = \Gamma(s) \zeta(1+s) \Lambda(s, v),$$

where $\Lambda$ has been defined in Lemma 1.

Again, $G^*(s, v)$ has a simple pole at $s = 1$ and a double pole at $s = 0$. At $s = 1$, the local expansion is

$$G^*(s, v) = \frac{A}{s-1} + O(1).$$

The local expansion around $s = 0$ is

$$G^*(s, v) = -\frac{B(v)}{s^2} + \frac{C(v)}{s} + O(1),$$

with $B(v)$ and $C(v)$ as in the statement of the lemma.

The rest of the proof follows along the lines of the proof of Lemma 2. □
Lemma 7. Let $r > 0$ and $z = r + it$ with $|t| \geq r^{7/5}$. Then
\[
\log D(r, u) - \Re \log D(z, u) \gg \frac{1}{r^{1/5}}
\]
for $u \in (\exp(-v_0 r/2), \exp(v_0 r/2))$ and $r \to 0^+$ unless there is a non-zero integer $k$ such that $|t - 2k\pi/\log \phi| < r^{3/4}$.

Proof. We have
\[
\Re \log D(z, u) = -\Re \sum_{m \in \mathcal{F}} \log(1 - um^{-z}) = \Re \sum_{m \in \mathcal{F}} \sum_{k \geq 1} \frac{u^k}{k} m^{-kz} = \sum_{m \in \mathcal{F}} \sum_{k \geq 1} \frac{u^k}{k} m^{-kr} \cos(kt \log m).
\]
This implies that
\[
\log D(r, u) - \Re \log D(z, u) = \sum_{m \in \mathcal{F}} \sum_{k \geq 1} \frac{u^k}{k} m^{-kr} (1 - \cos(kt \log m)) \geq u \sum_{m \in \mathcal{F}} m^{-r}(1 - \cos(t \log m)).
\]
The remainder of the proof is exactly the same as that of Lemma 3. □

Proof of Theorem 3. We now consider asymptotic expansions for $x \to \infty$; we set $r = \sqrt{A/\log x}$. The statements and proofs of Lemmata 4 and 5 carry over (only the range of $u$ has to be adapted). So we have
\[
\sum_{n \in \mathcal{M}(\mathcal{F})} u^{\Omega_x(n)} = \frac{1}{2\sqrt{\pi}} \exp\left(2\sqrt{A} \sqrt{\log x} - B(v) + \frac{1}{4} \log \log x + \frac{2B(v)}{4} - \frac{1}{4} \log A + C(v) \right) \times \left(1 + O\left(\frac{1}{(\log x)^{1/10}}\right)\right)
\]
for $x \to \infty$, $u \in U(\sqrt{A/\log x})$ and $v = \log u \sqrt{\log x}/A$.

We now consider the moment generating function
\[
\mathbb{E}(e^{\Omega_x(N)t}) = \frac{\sum_{n \in \mathcal{M}(\mathcal{F})} e^{\Omega_x(n)t}}{\sum_{n \in \mathcal{M}(\mathcal{F})} 1}.
\]
Equation (18) yields
\[
\mathbb{E}(e^{\Omega_x(N)t}) = \exp\left(\frac{1}{2} (\log \log x - \log A)(B(0) - B(v)) + C(v) - C(0) \right) \times \left(1 + O\left(\frac{1}{(\log x)^{1/10}}\right)\right),
\]
where $v = t\sqrt{\log x}/\sqrt{A}$, for all $t$ such that $|t| \leq v_0\sqrt{A}/(2\sqrt{\log x})$. Since $B(v) = -\Lambda(0, v)$, Equation (3) gives us $B(0) - B(v) = v/\log \phi$. Likewise, Lemmata 6 and 7 yield
\[
C(v) - C(0) = -\sum_{m \in \mathcal{F}} \left( \log \left(1 - \frac{v}{\log m}\right) + \frac{v}{\log m}\right) + \kappa_1 v,
\]
so finally
\[
E(e^{\Omega_\mathcal{F}(N)t}) = 
\exp\left(t \left( \frac{b_1}{2} \sqrt{\log x \log \log x} + b_1 \sqrt{\log x} \right) \right) \prod_{m \in \mathcal{F}} e^{-v/(\log m)} \left( 1 - \frac{v}{\log m} \right)^{-1} 
\times \left( 1 + O\left( \frac{1}{(\log x)^{1/10}} \right) \right),
\]

where \( b_1 = A^{-1/2}(\kappa_1 - (\log A)/(2\log \phi)) \). Since \( (1 - v/\lambda)^{-1} \) is exactly the moment generating function of an \( \text{Exp}(\lambda) \)-distributed random variable, Theorem 3 follows immediately from Curtiss’s theorem in the same way as Theorem 2. □
