Abstract

The oral route is the preferred route for drug delivery, among oral delivery Intestine and colon drug delivery have been used for molecules aimed at local treatment of colonic diseases such as Colon Cancer, Polyp, Colorectal, Crohn's Disease, Inflammatory Bowel Disease (IBD), Ulcerative Colitis (UC) etc. and for delivery of molecules susceptible to enzymatic degradation such as peptides. There are various methods have been reported for colon targeting, among them use of pH sensitive polymers for coating and formulation of drug delivery system is most beneficial. The formulations of pH sensitive nanoparticles, hydrogel, microspheres, Polymeric Micelles are commonly reported for colon targeting. This review focuses on advancements of pH sensitive drug delivery system for colon targeting.

Keywords: Colon delivery; pH sensitive polymers; Nanoparticles; Hydrogel; Microspheres; Eudragit

Introduction

To supply a therapeutic amount of drug to a target site in a body is the major goal of any conventional or novel drug delivery system. Targeted drug delivery shows effective and selective localization of drug into the target site at therapeutic concentrations with limited access to non-target sites. A targeted drug delivery system is also preferred in drugs having instability, low solubility and short biological life. The colon specific drug delivery system should be capable of protecting the drug till it gets released to the colon i.e. drug release and absorption should not occur in the stomach and the small intestine. The colon is supposed to be a suitable absorption site for drugs because of lack of digestive enzymes, relatively proteolytic activity of colon mucosa is much less in comparison to the small intestine which leads to greater systemic bioavailability, and finally a long residence time up to 24 hour [1].

The absorptive capacity of the colon is much less as compared to small intestine because of mucosal surface of colon resembles that of the small intestine at birth but changes with age causing the loss of villi leaving a flat mucosa with deep crypt cells. Generally colon specific delivery of drugs is of interest for the treatment of colonic diseases, so as to maximize the effectiveness of these drugs.

Approaches for targeting drugs into the colon

Colonic targeting is advantageous in treating diseases of colon i.e. Colon Cancer, Polyp, Colorectal, Crohn's Disease, Inflammatory Bowel Disease (IBD), Ulcerative Colitis (UC) etc., oral delivery of proteins and peptides where a delay in systemic absorption is therapeutically desirable (nocturnal asthma, arthritis).

Numerous invention approaches have been discovered to develop colon-targeted drug delivery systems. The difference in the pH along the GI tract is one of the approaches to achieve colon targeting, pH of different GI parts is given in Table 1. There are few methods have been developed for colon targeting i.e. utilization of Bacterial Enzymes, Time-Dependent Delivery System, pH-Triggered Delivery Systems.

Table 1: Characteristic of gastrointestinal tract. Intestinal diameter of Large intestinal - 6 cm.

| S.No. | Region Of Gastrointestinal Tract | Length (Cm) | Ph |
|-------|---------------------------------|-------------|----|
| 1     | Cecum                           | 6-7         | 5.5|
| 2     | Ascending Colon                 | 20          | 5.5-7|
| 3     | Transverse colon                | 45          | 5.5-7|
| 4     | Descending colon                | 30          | 5.5-7|
| 5     | Rectum                          | 12          | 7|
| 6     | Anal canal                      | 3           | -|

pH-triggered delivery systems

Radio telemetry shows the highest pH levels 7.5±0.5 in the terminal ileum. On entry into the colon, the pH drops to 6.4±06
and in the left colon 7.0±0.7 [2]. So the polymer has pH specific solubility at equivalent pH is beneficial for colon targeting. However, a pH dependent polymer can shield a formulation in the stomach, and proximal small intestine, it may start to dissolve in the lower small intestine.

Enteric coatings are widely used in the pharmaceutical industry and have been experimented extensively in attempts to target colon. The pH sensitive materials can be used to encapsulate drug. These can be engineered to remain stable at low pH, like those found in the stomach, and then release drugs at the higher pH of the intestine. Typically the polymers are carboxylated and interact (swell) very little with water at low pH, whilst at high pH the polymers ionize causing swelling, or dissolving of the polymer. Coatings can therefore be designed to remain intact in the acidic environment of the stomach (protecting either the drug from this environment of the stomach), but to dissolve in the more alkaline environment found at intestine/colon [3].

The primary group of polymers used for the preparation of colon targeted dosage forms has been the Eudragits (registered trademark of Rohm Pharma Darmstadt, Germany), more precisely Eudragits L and S which are anionic polymers that are water resistant at low pH. The ratio of the carboxyl to ester groups is almost 1:1 in Eudragit L 100 and 1:2 in Eudragit S100. These polymers form salts and dissolve at more than pH 7. Respectively Eudragit L 100 and S100 are copolymers of methacrylic acid and methyl methacrylate. The ratio of the carboxyl to ester groups is approximately 1:1 in Eudragit L 100-55, a copolymer of methacrylic acid and ethyl acrylate, which dissolves more than pH 5.5. This type of polymer disperses in water to form latex and avoids the use of organic solvents in the coating process. Eudragit L 30D-55 is a ready to use aqueous dispersion of Eudragit L 100-55 and is pH sensitive polymer Eudragit L100, S100 of capecitabine for targeted delivery to the colon. ThermocoatL30D55 has been reported to improve the shelf life of pellets, granules and powders and to improve self-protection against environmental effects like humidity, light, temperature, which was used to develop pH dependent Tulsion® microspheres for colon specific delivery using quasi emulsion spherical crystallization technique and a combined mechanism of release, which combines specific biodegradability of polymer and pH dependent release from the coated microspheres was proposed [4].

Shi et al. [7] studied about pH-sensitive and colon-targeting P(LE-IA-MEG) hydrogel microspheres used for ulcerative colitis therapy and demonstrated desirable colon targeting property from The pharmacokinetic studies. Agrawal et al. [8] Formulated separately colon targeted pH pendent microspheres using pH-sensitive polymer Eudragit L100, S100 of capecitabine for colorectal cancer to reduce dosing frequency and improve patient compliance.

**Hydrogels**

Hydrogels are cross-linked, hydrophilic polymeric networks that are able to absorb huge amounts of water within their 3-dimensional structures [9] It can be made to undergo sol-gel transition by various stimuli such as temperature and pH [5].

pH-sensitive hydrogels are found suitable candidates for oral delivery of therapeutic peptides, proteins, and drugs, due to their ability to respond to environmental pH changes in earlier studies. Mahlum 2006 prepared pH-sensitive glycopolymers for Colon-Specific Drug Delivery by free-radical polymerization of methacrylic acid and 6-acryloyl-glucose-1, 2, 3, 4-tetraacetate, using 1, 6-hexandiol diacrylate and 1, 6-hexandiol propoxylate diacylate as cross-linking agents.
Polymeric micelles

Polymeric micelles are nano-sized carriers having a spherical inner core and an outer shell prepared by self-assembly of amphiphilic copolymers in an aqueous solution [10]. The inhibition effect of Curcumin on tumor formation by affecting the initiation and progression stage of carcinogenesis of colorectal cancer has been investigated using Curcumin Containing Chitosan-Based pH-Sensitive Polymeric Micelles for Colon-Targeted Drug Delivery [11].

Conclusion

Both local and systemic delivery of drugs can take place at the site of colon. Among them local delivery allows topical treatment of various colonic diseases. As the pH varies at different parts of GIT pH sensitive polymers are insoluble at lower pH & get solubilized as the pH increases i.e., colon. Colon targeting makes the treatment effective by reducing the systemic side effects. Colon targeting also provide significant benefits to the patients in terms of safety, efficacy, and patient compliance. With combined methods, nanotechnology gives the impression to be a future research area for colon targeting.
