Abstract

We present a Bayesian nonparametric framework for multilevel clustering which utilizes group-level context information to simultaneously discover low-dimensional structures of the group contents and partitions groups into clusters. Using the Dirichlet process as the building block, our model constructs a product base-measure with a nested structure to accommodate content and context observations at multiple levels. The proposed model possesses properties that link the nested Dirichlet processes (nDP) and the Dirichlet process mixture models (DPM) in an interesting way: integrating out all contents results in the DPM over contexts, whereas integrating out group-specific contexts results in the nDP mixture over content variables. We provide a Polya-urn view of the model and an efficient collapsed Gibbs inference procedure. Extensive experiments on real-world datasets demonstrate the advantage of utilizing context information via our model in both text and image domains.

1. Introduction

In many situations, content data naturally present themselves in groups, e.g., students are grouped into classes, classes grouped into schools, words grouped into documents, etc. Furthermore, each content group can be associated with additional context information (teachers of the class, authors of the document, time and location stamps).

Proceedings of the 31st International Conference on Machine Learning, Beijing, China, 2014. JMLR: W&CP volume 32. Copyright 2014 by the author(s).
Recent work has attempted to jointly capture word topics and document clusters. Parametric approaches (Xie & Xing, 2013) are extensions of the LDA (Blei et al., 2003) and require specifying the number of topics and clusters in advance. Bayesian nonparametric approaches including the nested Dirichlet process (nDP) (Rodriguez et al., 2008) and the multi-level clustering hierarchical Dirichlet Process (MLC-HDP) (Wulsin et al., 2012) can automatically adjust the number of clusters. We note that none of these methods can utilize context data.

This paper proposes the Multilevel Clustering with Context (MC^2), a Bayesian nonparametric model to jointly cluster both content and groups while fully utilizing group-level context. Using the Dirichlet process as the building block, our model constructs a product base-measure with a nested structure to accommodate both content and context observations. The MC^2 model possesses properties that link the nested Dirichlet process (nDP) and the Dirichlet process mixture model (DPM) in an interesting way: integrating out all contents results in the DPM over contexts, whereas integrating out group-level context results in the nDP mixture over content variables. For inference, we provide an efficient collapsed Gibbs sampling procedure for the model.

The advantages of our model are: (1) the model automatically discovers the (unspecified) number of groups clusters and the number of topics while fully utilizing the context information; (2) content topic modeling is informed by group-level context information, leading to more predictive content topics; (3) the model is robust to partially missing context information. In our experiments, we demonstrate that our proposed model achieves better document clustering performances and more predictive word topics in real-world datasets in both text and image domains.

2. Related Background

There have been extensive works on clustering documents in the literature. Due to the limited scope of the paper, we only describe works closely related to probabilistic topic models. We note that standard topic models such as LDA (Blei et al., 2003) or its nonparametric Bayesian counterpart, HDP (Teh et al., 2006b) exploits the group structure for word clustering. However these models do not cluster documents.

An approach to document clustering is to employ a two-stage process. First, topic models (e.g. LDA or HDP) are applied to extract the topics and their mixture proportion for each document. Then, this is used as feature input to another clustering algorithm. Some examples of this approach include the use of LDA+Kmeans for image clustering (Xuan et al., 2011; Elango & Jayaraman, 2005) and HDP+Affinity Propagation for clustering human activities (Nguyen et al., 2013).

A more elegant approach is to simultaneously cluster documents and discover topics. The first Bayesian nonparametric model proposed for this task is the nested Dirichlet Process (nDP) (Rodriguez et al., 2008) where documents in a cluster share the same distribution over topic tokens. Although the original nDP does not force the topic tokens to be shared across document clusters, this can be achieved by simply introducing a DP prior for the nDP base measure. The same observation was also made by (Wulsin et al., 2012) who introduced the MLC-HDP, a 3-level extension to the nDP. This model thus can cluster words, documents and document-corpora with shared topic tokens throughout the group hierarchy. Xie et al (Xie & Xing, 2013) recently introduced the Multi-Grain Clustering Topic Model which allows mixing between global topics and document-cluster topics. However, this is a parametric model which requires fixing the number of topics in advance. More crucially, all of these existing models do not attempt to utilize group-level context information.

Modeling with Dirichlet Process

We provide a brief account of the Dirichlet process and its variants. The literature on DP is vast and we refer to (Hjort et al., 2010) for a comprehensive account. Here we focus on DPM, HDP and nDP which are related to our work.

Dirichlet process (Ferguson, 1973) is a basic building block in Bayesian nonparametrics. Let \( (\Theta, B, H) \) be a probability measure space, and \( \gamma \) is a positive number; a Dirichlet process \( DP(\gamma, H) \) is a distribution over discrete random probability measure \( G \) on \( (\Theta, B) \). Sethuraman (Sethuraman, 1994) provides an alternative constructive definition which makes the discreteness property of a draw from a Dirichlet process explicit via the stick-breaking representation:

\[
G = \sum_{k=1}^{\infty} \beta_k \delta_{\phi_k}, \quad \text{where} \quad \phi_k \sim H, \quad k = 1, \ldots, \infty \quad \text{and} \quad \beta = (\beta_k)_{k=1}^{\infty},
\]

are the weights constructed through a ‘stick-breaking’ process \( \beta_k = v_k \prod_{s<k} (1 - v_s) \) with \( v_k \sim \text{Beta}(1, \gamma) \). It can be shown that \( \sum_{k=1}^{\infty} \beta_k = 1 \) with probability one, and as a convention (Pitman, 2002), we hereafter write \( \beta \sim \text{GEM}(\gamma) \).

Due to its discrete nature, Dirichlet process has been widely used in Bayesian mixture models as the prior distribution on the mixing measures, each is associated with an atom \( \phi_k \) in the stick-breaking representation of \( G \) above. A likelihood kernel \( F(\cdot) \) is used to generate data \( x_i \mid \phi_k \sim F(\cdot \mid \phi_k) \), resulting in a model known as the Dirichlet process mixture model (DPM), pioneered by the work of (Antoniak, 1974) and subsequently developed by many others. In section 3 we provide a precise definition for
DPM.

While DPM models exchangeable data within a single group, the Dirichlet process can also be constructed hierarchically to provide prior distributions over multiple exchangeable groups. Under this setting, each group is modelled as a DPM and these models are ‘linked’ together to reflect the dependency among them – a formalism which is generally known as dependent Dirichlet processes (MacEachern, 1999). One particular attractive approach is the hierarchical Dirichlet processes (Teh et al., 2006b) which posits the dependency among the group-level DPM by another Dirichlet process, i.e., \( G_{j} \mid \alpha, G_{0} \sim \text{DP} (\alpha, G_{0}) \) and \( G_{0} \mid \gamma, H \sim \text{DP} (\gamma, H) \) where \( G_{j} \) is the prior for the \( j \)-th group, linked together via a discrete measure \( G_{0} \) whose distribution is another DP.

Yet another way of using DP to model multiple groups is to construct random measure in a nested structure in which the DP base measure is itself another DP. This formalism is the nested Dirichlet Process (Rodriguez et al., 2008), specifically \( G_{j} \overset{iid}{\sim} U \) where \( U \sim \text{DP} (\alpha \times \text{DP} (\gamma H)) \). Modeling \( G_{j} \) hierarchically as in HDP and nestedly as in nDP yields different effects. HDP focuses on exploiting statistical strength across groups via sharing atoms \( \phi_{k} \) (s), but it does not partition groups into clusters. This statement is made precisely by noting that \( P(G_{j} = G_{j'}) = 0 \) in HDP. Whereas, nDP emphasizes on inducing clusters on both observations and distributions, hence it partitions groups into clusters. To be precise, the prior probability of two groups being clustered together is \( P(G_{j} = G_{j'}) = \frac{1}{\delta + 1} \). Finally we note that this original definition of nDP in (Rodriguez et al., 2008) does not force the atoms to be shared across clusters of groups, but this can be achieved by simply introducing a DP prior for the nDP base measure, a modification that we use in this paper. This is made clearly in our definition for nDP mixture in section 3.

3. Multilevel Clustering with Contexts

3.1. Model description and stick-breaking

Consider data presented in a two-level group structure as follows. Denote by \( J \) the number of groups; each group \( j \) contains \( N_{j} \) exchangeable data points, represented by \( w_{j} = \{ w_{j1}, w_{j2}, \ldots, w_{jN_{j}} \} \). For each group \( j \), the group-specific context data is denoted by \( x_{j} \). Assuming that the groups are exchangeable, the overall data is \( \{ (x_{j}, w_{j}) \}_{j=1}^{\infty} \).

The collection \( \{ w_{1}, \ldots, w_{J} \} \) represents observations of the group contents, and \( \{ x_{1}, \ldots, x_{J} \} \) represents observations of the group-level contexts.

We now describe the generative process of MC\(^{2}\) that generates a two-level clustering of this data. We use a group-level DP mixture to generate an infinite cluster model for groups. Each group cluster \( k \) is associated with an atom having the form of a pair \( (\phi_{k}, Q_{k}^{\ast}) \) where \( \phi_{k} \) is a parameter that generates the group-level contexts within the cluster and \( Q_{k}^{\ast} \) is a measure that generates the group contents within the same cluster.

To generate atomic pairs of context parameter and measure-valued content parameter, we introduce a product base-measure of the form \( H \times \text{DP}(vQ_{0}) \) for the group-level DP mixture. Drawing from a DP mixture with this base measure, each realization is a pair \( (\theta_{j}, Q_{j}) \); \( \theta_{j} \) is then used to generate the context \( x_{j} \) and \( Q_{j} \) is used to repeatedly produce the set of content observations \( w_{ji} \) within the group \( j \).

Specifically,

\[
U \sim \text{DP} (\alpha (H \times \text{DP}(vQ_{0}))) \quad \text{where} \quad Q_{0} \sim \text{DP} (\eta S) \quad (\theta_{j}, Q_{j}) \overset{iid}{\sim} U \text{ for each group } j \quad (1)
\]

\[
x_{j} \sim F(\cdot | \theta_{j}) \quad \varphi_{ji} \overset{iid}{\sim} Q_{j} \quad w_{ji} \sim Y(\cdot | \varphi_{ji})
\]

In the above, \( H \) and \( S \) are respectively base measures for context and content parameters \( \theta_{j} \) and \( \varphi_{ji} \). The context and content observations are then generated via the likelihood kernels \( F(\cdot | \theta_{j}) \) and \( Y(\cdot | \varphi_{ji}) \). To simplify inference, \( H \) and \( S \) are assumed to be conjugate to \( F \) and \( Y \) respectively. The generative process is illustrated in Figure 1.

**STICK-BREAKING REPRESENTATION**

We now derive the stick-breaking construction for MC\(^{2}\) where all the random discrete measures are specified by a distribution over integers and a countable set of atoms. The random measure \( U \) in Eq. (7) has the stick-breaking form:

\[
U = \sum_{k=1}^{\infty} \pi_{k} \delta(\phi_{k}, Q_{k}^{\ast}) \quad (2)
\]

where \( \pi \sim \text{GEM}(\alpha) \) and \( (\phi_{k}, Q_{k}^{\ast}) \overset{iid}{\sim} H \times \text{DP}(vQ_{0}) \). Equivalently, this means \( \phi_{k} \) is drawn i.i.d. from \( H \) and \( Q_{k}^{\ast} \) drawn i.i.d. from \( \text{DP}(vQ_{0}) \). Since \( Q_{0} \sim \text{DP}(\eta S) \), \( Q_{0} \) and \( Q_{k}^{\ast} \) have the standard HDP (Teh et al., 2006b)
Bayesian Nonparametric Multilevel Clustering with Group-Level Contexts

stick-breaking forms: \( Q_0 = \sum_{m=1}^{\infty} \epsilon_m \delta_{\psi_m} \) where \( \epsilon \sim \text{GEM}(\eta) \), \( \psi_m \overset{\text{iid}}{\sim} S \); \( Q_k = \sum_{m=1}^{\infty} \tau_{k,m} \delta_{\psi_m} \) where \( \tau_k = (\tau_{k1}, \tau_{k2}, \ldots) \sim \text{DP}(v, \epsilon) \).

For each group \( j \) we sample the parameter pair \((\theta_j, Q_j) \overset{\text{iid}}{\sim} U\); equivalently, this means drawing \( z_j \overset{\text{iid}}{\sim} \pi \) and letting \( \theta_j = \phi_{z_j} \) and \( Q_j = Q_{z_j} \). For the \( i \)-th content data within the group \( j \), the content parameter \( \phi_{ji} \) is drawn \( \sim Q_j = Q_{z_j} \); equivalently, this means drawing \( l_{ji} \overset{\text{iid}}{\sim} \tau_j \) and letting \( \phi_{ji} = \psi_{l_{ji}} \). Figure 1 presents the graphical model of this stick-breaking representation.

### 3.2. Inference and Polya Urn View

We use collapsed Gibbs sampling, integrating out \( \phi_{z}(s), \psi_{\theta}(s), \pi \) and \( \tau(k) \). Latent variables \( z, l, \epsilon \) and the hyper-parameters \( \alpha, v, \eta \) will be resampled. We only describe the key inference steps in sampling \( z \) and \( \epsilon \) here and refer to Appendix A.2 for the rest of the details (including how to sample the hyper-parameters).

**Sampling \( z \).** The required conditional distribution is

\[
p(z_j = k \mid z_{-j}, l, x, \alpha, H) \propto \frac{p(z_j = k) p(x_j \mid z_j = k, z_{-j}, x_{-j}, H)}{p(l_j \mid z_j = k, l_{-j}, x_{-j}, \epsilon, v)}
\]

The first term can be recognized as a form of the Chinese restaurant process (CRP). The second term is the predictive likelihood for the content observations under the component \( \phi_k \) after integrating out \( \phi_k \). This can be evaluated analytically due to conjugacy of \( F \) and \( H \). The last term is the predictive likelihood for the group content-index \( l_j = \{ l_{ji} \mid i = 1 \ldots N_j \} \). Since \( l_{ji} \mid z_j = k \overset{\text{iid}}{\sim} \text{Mult}(\tau_k) \), where \( \tau_k \sim \text{Dir}(v_1, \ldots, v_M, \epsilon_{\text{new}}) \), the last term can also be evaluated analytically by integrating out \( \tau_k \) using the Multinomial-Dirichlet conjugacy property.

**Sampling \( l \).** Let \( w_{-ji} \) be the same set as \( w \) excluding \( w_{ji} \), let \( w_{-ji}(m) = \{ w_{ji'} \mid (j', i') \neq (j, i) \land j' \neq m \} \) and \( L_{-ji}(k) = \{ l_{ji'} \mid (j', i') \neq (j, i) \land z_{j'} = k \} \). Then

\[
p(l_{ji} \mid m, l_{-ji}, z_j = k, z_{-j}, v, w, \epsilon, S) \propto p(w_{ji} \mid l_{-ji}, S) p(l_{ji} = m \mid l_{-ji}, z_j = k, z_{-j}, \epsilon, v) = p(w_{ji} \mid w_{-ji}(m), S) p(l_{ji} = m \mid L_{-ji}(k), \epsilon, v)
\]

The first term is the predictive likelihood under mixture component \( \psi_m \) after integrating out \( \psi_m \), which can be evaluated analytically due to the conjugacy of \( Y \) and \( S \). The second term is in the form of a CRP similar to the one that arises during inference for HDP (Teh et al., 2006b).

**Sampling \( \epsilon \).** Sampling \( \epsilon \) requires information from both \( z \) and \( l \).

\[
p(\epsilon \mid I, z, v, \eta) \propto p(I \mid \epsilon, v, z, \eta) \times p(\epsilon \mid \eta)
\]

Using a similar strategy in HDP, we introduce auxiliary variables \( \epsilon_{km} \), then alternatively sample together with \( \epsilon \):

\[
p(\epsilon \mid \eta) \propto \epsilon_{\text{new}}^{-1} \prod_{m=1}^{M} \epsilon_{km}^{\eta_{km}} - 1
\]

where \( \text{Stir}(h, n_{km}) \) is the Stirling number of the first kind, \( n_{km} \) is the count of seeing the pair \((z_j = k, l_{ji} = m) : \forall i, j \) and finally \( M \) is the current number of active content topics. It clear that \( \epsilon_{km} \) can be sampled from a Multinomial distribution and \( \epsilon \) from an \((M + 1)\)-dim Dirichlet distribution.

### POLYA URN VIEW

Our model exhibits a Polya-urn view using the analogy of a fleet of buses, driving customers to restaurants. Each bus represents a group and customers on the bus are data points within the group. For each bus \( j \), \( z_j \) acts as the index to the restaurant for its destination. Thus, buses form clusters at their destination restaurants according to a CRP: a new bus drives to an existing restaurant with the probability proportional to the number of other buses that have arrived at that restaurant, and with probability proportional to \( \alpha \), it goes to a completely new restaurant.

Once all the buses have delivered customers to the restaurants, all customers at the restaurants start to behave in the same manner as in a Chinese restaurant franchise (CRF) process: customers are assigned tables according to a restaurant-specific CRP; tables are assigned with dishes \( \psi_m \) (representing the content topic atoms) according to a global franchise CRP. In addition to the usual CRF, at restaurant \( k \), a single dessert \( \phi_k \) (which represents the context-generating atom, drawing \( \sim \text{from} H \) will be served to all the customers at that restaurant. Thus, every customer on the same bus \( j \) will be served the same dessert \( \phi_z \). We observe three sub-CRPs, corresponding to the three DP(s) in our model: the CRP at the dish level is due to the DP \((\eta S)\), the CRP forming tables inside each restaurant is due to the DP \((vQ_0)\), and the CRP aggregating buses to restaurants is due to the DP \((\alpha(H \times DP(vQ_0)))\).

### 3.3. Marginalization property

We study marginalization property for our model when either the content topics \( \phi_{ji} (s) \) or context topics \( \theta_j (s) \) are marginalized out. Our main result is established in Theorem 9 where we show an interesting link to nested DP and DPM via our model.

Let \( H \) be a measure over some measurable spaces \((\Theta, \Sigma)\). Let \( \mathbb{P} \) be the set of all measures over \((\Theta, \Sigma)\), suitably endowed with some \( \sigma \)-algebra. Let \( G \sim \text{DP}(\alpha H) \)
\(\theta_i \overset{iid}{\sim} G\). The collection \((\theta_i)\) then follows the DP mixture distribution which is defined formally below.

**Definition 1.** (DPM) A DPM is a probability measure over \(\Theta^n \ni (\theta_1, \ldots, \theta_n)\) with the usual product sigma algebra \(\Sigma^n\) such that for every collection of measurable sets \(\{(S_1, \ldots, S_n): S_i \in \Sigma, i = 1, \ldots, n\}\):

\[
\text{DPM}(\theta_1 \in S_1, \ldots, \theta_n \in S_n | \alpha, H) = \int \prod_{i=1}^n G(S_i) \text{DPM} (dG | \alpha H)
\]

We now state a result regarding marginalization of draws from a DP mixture with a joint base measure. Consider two measurable spaces \((\Theta_1, \Sigma_1)\) and \((\Theta_2, \Sigma_2)\) and let \((\Theta, \Sigma)\) be their product space where \(\Theta = \Theta_1 \times \Theta_2\) and \(\Sigma = \Sigma_1 \times \Sigma_2\). Let \(H^*\) be a measure over the product space \(\Theta = \Theta_1 \times \Theta_2\) and let \(H_1\) be the marginal of \(H^*\) over \(\Theta_1\) in the sense that for any measurable set \(A \in \Sigma_1, H_1(A) = H^*(\pi \times \Theta_2)\). Then drawing \((\theta_1^{(1)}, \theta_2^{(1)})\) from a DP mixture with base measure \(\alpha H\) and marginalizing out \((\theta_2^{(2)})\) is the same as drawing \((\theta_1^{(1)})\) from a DP mixture with base measure \(H_1\).

**Proposition 2.** Denote by \(\theta_i\) the pair \((\theta_1^{(i)}, \theta_2^{(i)})\), there holds

\[
\text{DPM} \left( \theta_1^{(1)} \in S_1, \ldots, \theta_n^{(1)} \in S_n | \alpha H_1 \right) = \text{DPM} \left( \theta_1 \in S_1 \times \Theta_2, \ldots, \theta_n \in S_n \times \Theta_2 | \alpha H^* \right)
\]

for every collection of measurable sets \(\{(S_1, \ldots, S_n): S_i \in \Sigma, i = 1, \ldots, n\}\).

**Proof.** see Appendix 7.

Next we give a formal definition of the nDPM mixture:

\[\varphi_{ji} \overset{iid}{\sim} Q_j, \quad Q_j \overset{iid}{\sim} U, \quad U \sim \text{DP}(\alpha \text{DP}(vQ_0)), \quad Q_0 \sim \text{DP}(\eta S)\]

**Definition 3.** (nested DPM Mixture) An nDPM is a probability measure over \(\Theta \times \Sigma_{1=1}^J N_j \ni (\varphi_{11}, \ldots, \varphi_{1N_1}, \ldots, \varphi_{JN_J})\) equipped with the usual product sigma algebra \(\Sigma_{1=1}^J N_j \times \ldots \times \Sigma_{1=1}^J N_j\) such that for every collection of measurable sets \(\{(S_{ji}): S_{ji} \in \Sigma, j = 1, \ldots, J, i = 1, \ldots, N_j\}\):

\[
n\text{DPM} (\varphi_{ji} \in S_{ji}, \forall j | \alpha, v, \eta, S) = \int \int \left\{ \prod_{j=1}^J \left\{ \int \prod_{i=1}^{N_j} Q_j (S_{ji}) U (dQ_j) \right\} \right\} \times \text{DP} (dU | \alpha \text{DP}(vQ_0)) \text{DP} (dQ_0 | \eta, S)
\]

We now have the sufficient formalism to state the marginalization result for our model.

**Theorem 4.** Given \(\alpha, H\) and \(\alpha, v, \eta, S\), let \(\theta = (\theta_j: \forall j)\) and \(\varphi = (\varphi_{ji}: \forall j, i)\) be generated as in Eq (7). Then, marginalizing out \(\varphi\) results in \(\text{DPM}(\theta | \alpha, H)\), whereas marginalizing out \(\theta\) results in \(n\text{DPM}(\varphi|\alpha, v, \eta, S)\).

**Proof.** We sketch the main steps, Appendix 9 provides more detail. Let \(H^* = H_1 \times H_2\), we note that when either \(H_1\) or \(H_2\) are random, a result similar to Proposition 7 still holds by taking the expectation on both sides of the equality. Now let \(H_1 = H\) and \(H_2 = DP(vQ_0)\) where \(Q_0 \sim DP(\eta S)\) yields the proof for the marginalization of \(\varphi\): let \(H_1 = DP(vQ_0)\) and \(H_2 = H\) yields the proof for the marginalization of \(\theta\).

4. Experiments

We first evaluate the model via simulation studies, then demonstrate its applications on text and image modeling using three real-world datasets. Throughout this section, unless explicitly stated, discrete data is modeled by Multinomial with Dirichlet prior, while continuous data is modeled by Gaussian (unknown mean and unknown variance) with Gaussian-Gamma prior.

4.1. Simulation studies

The main goal is to investigate the posterior consistency of the model, i.e., its ability to recover the true group clusters, context distribution and content topics. To synthesize the data, we use \(M = 13\) topics which are the 13 unique letters in the ICML string “INTERATIONAL CONFERENCE MACHINE LEARNING”. Similar to (Griffiths & Steyvers, 2004), each topic \(\psi_m\) is a distribution over 35 words (pixels) and visualized as a \(7 \times 5\) binary image. We generate \(K = 4\) clusters of 100 documents each. For each cluster, we choose a set of topics corresponding to letters in the each of 4 words in the ICML string. The topic mixing distribution \(\tau_k\) is an uniform distribution over the chosen topic letters. Each cluster is also assigned a context-generating univariate Gaussian distribution. These generating parameters are shown in Figure 2 (left). Altogether we have \(J = 400\) documents; for each document we sample \(N_j = 50\) words and a context variable \(x_j\) drawing from the cluster-specific Gaussian.

We model the word \(w_{ji}\) with Multinomial and Gaussian for context \(x_j\). After 100 Gibbs iterations, the number of context and content topics \((K = 4, M = 13)\) are recovered correctly: the learned context atoms \(\phi_k\) and topic \(\psi_m\) are almost identical to the ground truth (Figure 2, right) and the model successfully identifies the 4 clusters of documents with topics corresponding to the 4 words in the ICML string.

To demonstrate the importance of context observation, we
Bayesian Nonparametric Multilevel Clustering with Group-Level Contexts

then run LDA and HDP with only the word observations (ignoring context) where the number of topic of LDA is set to 13. As can be seen from Figure 2 (right), LDA and HDP have problems in recovering the true topics. They cannot distinguish small differences between the overlapping character topics (e.g. M vs N, or I vs T). Further analysis of the role of context in MC$^2$ is provided in Appendix A.3.

4.2. Experiments with Real-World Datasets

We use two standard NIPS and PNAS text datasets, and the NUS-WIDE image dataset. 

NIPS contains 1,740 documents with vocabulary size 13,649 (excluding stop words); timestamps (1987-1999), authors (2,037) and title information are available and used as group-level context. PNAS contains 79,800 documents, vocab size = 36,782 with publication timestamp (915-2005). For NUS-WIDE we use a subset of the 13-class animals$^1$ comprising of 3,411 images (2,054 images for training and 1357 images for testing) with off-the-shelf features including 500-dim bag-of-word SIFT vector and 1000-dim bag-of-tag annotation vector.

Text Modeling with Document-Level Contexts
We use NIPS and PNAS datasets with 90% for training and 10% for held-out perplexity evaluation. We compare the perplexity with HDP (Teh et al., 2006b) where no group-level context can be used, and npTOT (Dubey et al., 2012) where only timestamp information can be used. We note that unlike our model, npTOT requires replication of document timestamp for every word in the document, which is somewhat unnatural.

We use perplexity score (Blei et al., 2003) on held-out data as performance metric, defined as $\exp \left\{ - \sum_{j=1}^{J} \log p \left( w_{j}^{\text{test}} | x_{j}^{\text{train}}, w_{j}^{\text{train}} \right) \right\} / \left\langle \sum_{j} N_{j}^{\text{test}} \right\rangle$.

To ensure fairness and comparable evaluation, only words in held-out data is used to compute the perplexity. We used univariate Gaussian for timestamp and Multinomial distributions for words, tags and authors. We ran collapsed Gibbs for 500 iterations after 100 burn-in samples.

Table 1 shows the results where MC$^2$ achieves significant better performance. This shows that group-level context information during training provide useful guidance for the modelling tasks. Regarding the informative aspect of group-level context, we achieve better perplexity with timestamp information than with titles and authors. This may be explained by the fact that 1361 authors (among 2037) show up only once in the data while title provides little additional information than what already in that abstracts. Interestingly, without the group-level context information, our model still predicts the held-out words better than HDP. This suggests that inducing partitions over documents simultaneously with topic modelling is beneficial.

Beyond the capacity of HDP and npTOT, our model can induce clusters over documents (value of $K$ in Table 1). Figure 3 shows an example of one such document cluster discovered from NIPS data with authors as context. Our proposed model also allows flexibility in deriving useful understanding into the data and to evaluate on its predictive capacity (e.g., who most likely wrote this article, which authors work in the same research topic and so on). Another possible usage is to obtain conditional distributions among context topics $\phi_k(s)$ and content topics $\psi_m(s)$. For example if the context information is timestamp, the model immediately yields the distribution over time for $\theta_k(s)$.

| MC² with timestamp      | **895.3** (12, 117)        | **984.7** (15, 95) | words+timestamp |

Table 1. Perplexity evaluation on PNAS and NIPS datasets. (K,M) is (#cluster,#topic). (Note: missing results are due to title and author information not available in PNAS dataset).

Table 2. NUS-WIDE dataset. Perplexity is evaluated on SIFT feature.

Figure 3. An example of document cluster from NIPS. Top: distribution over authors. Middle: examples of paper titles. Bottom: examples of word topics in this cluster.

Figure 4. Topic Albinism discovered from PNAS dataset and its conditional distribution over time using our model; plotted together with results independently searched from Google Scholar using the top 50 hits.

a topic, showing when the topic rises and falls. Figure 4 illustrates an example of a distribution over time for a content topic discovered from PNAS dataset where timestamp was used as context. This topic appears to capture a congenital disorder known as Albinism. This distribution illustrates research attention to this condition over the past 100 years from PNAS data. To seek evidence for this result, we search the term “Albinism” in Google Scholar, using the top 50 searching results and plot the histogram over time in the same figure. Surprisingly, we obtain a very close match between our results and the results from Google Scholar as evidenced in the figure.

Image Clustering with Image-Level Tags
We evaluate the clustering capacity of MC² using contexts on an image clustering task. Our dataset is NUS-WIDE described earlier. We use bag-of-word SIFT features from each image for its content. Since each image in this dataset comes with a set of tags, we exploit them as context information, hence each context observation $x_j$ is a bag-of-tag annotation vector.

First we perform the perplexity evaluation for this dataset using a similar setting as in the previous section. Table 2 presents the results where our model again outperforms HDP even when no context (tags) is used for training.

Next we evaluate the clustering quality of the model using the provided 13 classes as ground truth. We report performance on four well-known clustering evaluation metrics: Purity, Normalized Mutual Information (NMI), Rand-Index (RI), and Fscore (detailed in (Rand, 1971; Cai et al., 2011)). We use the following baselines for comparison:

- Kmeans and Non-negative Matrix Factorization (NMF) (Lee & Seung, 1999). For these methods, we need to specify the number of clusters in advance, hence we vary this number from 10 to 40. We then report the min, max, mean and standard deviation.
- Affinity Propagation (AP) (Frey & Dueck, 2007): AP
Bayesian Nonparametric Multilevel Clustering with Group-Level Contexts

Figure 5. Clustering performance measured in purity, NMI, Rand-Index and F-score using NUS-WIDE dataset.

Figure 6. Projecting 7 discovered clusters (among 28) on 2D using t-SNE (Van der Maaten & Hinton, 2008).

Table 3. Clustering performance with different missing proportion of context observation $x_j$.

| Missing (%) | Purity | NMI  | RI   | F-score |
|------------|-------|------|------|--------|
| 0 %        | 0.407 | 0.298| 0.901| 0.157  |
| 25 %       | 0.338 | 0.245| 0.892| 0.149  |
| 50 %       | 0.320 | 0.236| 0.883| 0.137  |
| 75 %       | 0.313 | 0.187| 0.860| 0.112  |
| 100 %      | 0.306 | 0.188| 0.867| 0.119  |

5. Conclusion

We have introduced an approach for multilevel clustering when there are group-level context information. Our MC$^2$ provides a single joint model for utilizing group-level contexts to form group clusters while discovering the shared topics of the group contents at the same time. We provide a collapsed Gibbs sampling procedure and perform extensive experiments on three real-world datasets in both text and image domains. The experimental results using our model demonstrate the importance of utilizing context information in clustering both at the content and at the group level. Since similar types of contexts (time, tags, locations, ages, genres) are commonly encountered in many real-world data sources, we expect that our model will also be further applicable in other domains.

Our model contains a novel ingredient in DP-based Bayesian nonparametric modeling: we propose to use a base measure in the form of a product between a context-generating prior $H$ and a content-generating prior $\text{DP}(\psi Q_0)$. Doing this results in a new model with one marginal being the DPM and another marginal being the nDP mixture, thus establishing an interesting bridge between the DPM and the nDP. Our product base measure construction can be generalized to yield new models suitable for data presenting in more complicated nested group structures (e.g., more than 2-level deep).

A. Appendix

This note provides supplementary information for the main paper. It has three parts: a) the proof for the marginalization property of our proposed model, b) detailed derivations for our inference, and c) equations to show how the perplexity in the experiment was computed.

A.1. Proof for Marginalization Property (Theorem 4)

We start with a proposition on the marginalization result for DPM with the product measure then move on the final proof for our proposed model.

A.1.1. Marginalization of DPM with Product Measure

Let \( H \) be a measure over some measurable space \( (\Theta, \Sigma) \). Let \( \mathbb{P} \) be the set of all measures over \( (\Theta, \Sigma) \), suitably endowed with some \( \sigma \)-algebra. Let \( G \sim \text{DP}(\alpha H) \) be a draw from a Dirichlet process.

**Lemma 5.** Let \( S_1, \ldots, S_n \) be \( n \) measurable sets in \( \Sigma \). We form a measurable partition of \( \Theta \), a collection of disjoint measurable sets, that generate \( S_1, \ldots, S_n \) as follows. If \( S \) is a set, let \( S^1 = S \) and \( S^{-1} = \Theta \setminus S \). Then \( S^* = \{ \bigcap_{i=1}^n S_i^* \mid c_i \in \{1, -1\} \} \) is a partition of \( \Theta \) into a finite collection of disjoint measurable sets with the property that any \( S_i \) can be written as a union of some sets in \( S^* \). Let the element of \( S^* \) be \( A_1 \ldots A_n^* \) (note \( n^* \leq 2^n \)). Then the expectation

\[
\mathbb{E}_G[G(S_1), \ldots, G(S_n)] = \int \prod_{i=1}^n G(S_i) \, d\text{DP}(dG \mid \alpha H) \tag{4}
\]

depends only on \( \alpha \) and \( H(A_i) \). In other words, the above expectation can be written as a function \( E_n(\alpha, H(A_1), \ldots, H(A_n^*)) \).

It is easy to see that since \( S_i \) can always be expressed as the sum of some disjoint \( A_i \), \( G(S_i) \) can respectively be written as the sum of some \( G(A_i) \). Furthermore, by definition of a Dirichlet process, the vector \( (G(A_1), \ldots, G(A_n^*)) \) distributed according to a finite Dirichlet distribution \( (\alpha H(A_1), \ldots, \alpha H(A_n^*)) \), therefore the expectation \( \mathbb{E}_G[G(S_i)] \) depends only on \( \alpha \) and \( H(A_i) \) (s).

**Definition 6.** (DPM) A DPM is a probability measure over \( \Theta^n \supseteq (\theta_1, \ldots, \theta_n) \) with the usual product sigma algebra \( \Sigma^n \) such that for every collection of measurable sets \( \{(S_1, \ldots, S_n) : S_i \in \Sigma, i = 1, \ldots, n\} \):

\[
\text{DPM}(\theta_1 \in S_1, \ldots, \theta_n \in S_n | \alpha, H) = \int \prod_{i=1}^n G(S_i) \, \text{DP}(dG \mid \alpha H) \tag{6}
\]

Consider two measurable spaces \( (\Theta_1, \Sigma_1) \) and \( (\Theta_2, \Sigma_2) \) and let \( (\Theta, \Sigma) \) be their product space where \( \Theta = \Theta_1 \times \Theta_2 \) and \( \Sigma = \Sigma_1 \times \Sigma_2 \). We present the general theorem that states the marginal result from a product base measure.

**Proposition 7.** Let \( H^* \) be a measure over the product space \( \Theta = \Theta_1 \times \Theta_2 \). Let \( H_1 \) be the marginal of \( H^* \) over \( \Theta_1 \) in the sense that for any measurable set \( A \in \Sigma_1 \), \( H_1(A) = H^*(A \times \Theta_2) \). Denote by \( \theta_i \) the pair \( (\theta_i^{(1)}, \theta_i^{(2)}) \), then:

\[
\text{DPM} \left( \theta_1^{(1)} \in S_1, \ldots, \theta_n^{(1)} \in S_n | \alpha H_1 \right) = \text{DPM} \left( \theta_1 \in S_1 \times \Theta_2, \ldots, \theta_n \in S_n \times \Theta_2 | \alpha H^* \right)
\]

for every collection of measurable sets \( \{(S_1, \ldots, S_n) : S_i \in \Sigma_1, i = 1, \ldots, n\} \).

**Proof.** Since \( \{(S_1, \ldots, S_n) : S_i \in \Sigma_1, i = 1, \ldots, n\} \) are rectangles, expanding the RHS using Definition 6 gives:

\[
\text{RHS} = \int G(S_1 \times \Theta_2) \ldots G(S_n \times \Theta_2) \, d\text{DP}(dG | \alpha, H^*)
\]

Let \( T_i = S_i \times \Theta_2 \), the above expression is the expectation of \( \prod_i G(T_i) \) when \( G \sim \text{DP}(\alpha H^*) \). Forming collection of the disjoint measurable sets \( T^* = (B_1 \ldots B_n^*) \) that generates \( T_i \), then note that \( B_i = A_i \times \Theta_2 \), and \( S^* = (A_1 \ldots A_n^*) \) generates \( S_i \). By definition of \( H_1 \), \( H_1(A_i) = H^*(A_i \times \Theta_2) = H^*(B_i) \). Using the Lemma 5 above, \( \text{RHS} = E_n(\alpha, H^*(B_1) \ldots H^*(B_n^*)) \), while \( \text{LHS} = E_n(\alpha, H_1(A_1) \ldots H_1(A_n^*)) \) and they are indeed the same.

We note that \( H^* \) can be any arbitrary measure on \( \Theta \) and, in general, we do not require \( H^* \) to factorize as product measure.

A.1.2. Marginalization Result for Our Proposed Model

Recall that we are considering a product base-measure of the form \( H^* = H \times \text{DP}((\epsilon Q_0) \) for the group-level DP mixture. Drawing from a DP mixture with this base measure, each realization is a pair \((\theta_j, Q_j)\); \( \theta_j \) is then used to generate the context \( x_j \) and \( Q_j \) is used to repeatedly generate the
set of content observations \( w_{ji} \) within the group \( j \). Specifically,

\[
U \sim \text{DP} \left( \alpha(H \times \text{DP}(vQ_0)) \right) \quad \text{where} \quad Q_0 \sim \text{DP}(\eta S)
\]

\[
(\theta_j, Q_j) \overset{\text{iid}}{\sim} U \quad \text{for} \quad j = 1, \ldots, J
\]

\[
\varphi_{ji} \overset{\text{iid}}{\sim} Q_j, \quad \text{for each} \quad j \quad \text{and} \quad i = 1, \ldots, N_j
\]

In the above, \( H \) and \( S \) are respectively base measures for context and content parameters \( \theta_j \) and \( \varphi_{ji} \). We start with a definition for nested Dirichlet Process Mixture (nDPM) to proceed further.

**Definition 8.** (nested DP Mixture) An nDPM is a probability measure over \( \Theta^N \ni (\varphi_{11}, \ldots, \varphi_{1N_1}, \ldots, \varphi_{N_j}N_j) \) equipped with the usual product sigma algebra \( \Sigma^N \times \ldots \times \Sigma^{N_j} \) such that for every collection of measurable sets \( \{ (S_{ji}) : S_{ji} \in \Theta, j = 1, \ldots, J, i = 1, \ldots, N_j \} \):

\[
nDPM(\varphi_{ji} \in S_{ji}, \forall i, j | \alpha, \eta, S) = \int \int \left\{ \prod_{j=1}^{N_j} \prod_{i=1}^{N_i} Q_{ji} (S_{ji}) U (dQ_{ji}) \right\} \times \text{DP}(dU | \alpha \text{DP}(vQ_0)) \quad \text{DP}(dQ_0 | \eta, S) \n\]

We now state the main marginalization result for our proposed model.

**Theorem 9.** Given \( \alpha, H \) and \( \alpha, v, \eta, S, \) let \( \theta = (\theta_j : \forall j) \) and \( \varphi = (\varphi_{ji} : \forall i, j) \) be generated as in Eq (7). Then, marginalizing out \( \varphi \) results in \( \text{DPM}(\theta | \alpha, H) \), whereas marginalizing out \( \theta \) results in \( nDPM(\varphi | \alpha, v, \eta, S) \).

**Proof.** First we make observation that if we can show Proposition 7 still holds when \( H_1 \) is random with \( H_2 \) is fixed and vice versa, then the proof required is an immediate corollary of Proposition 7 by letting \( H^* = H_1 \times H_2 \) where we first let \( H_1 = H, H_2 = \text{DP}(vQ_0) \) to obtain the proof for the first result, and then swap the order \( H_1 = \text{DP}(vQ_0), H_2 = H \) to get the second result.

To see that Proposition 7 still holds when \( H_2 \) is a random measure and \( H_1 \) is fixed, we let the product base measure \( H^* = H_1 \times H_2 \) and further let \( \mu \) be a prior probability measure for \( H_2, \text{i.e.} H_2 \sim \mu(\cdot) \). Denote by \( \theta_i \) the pair \( \left( \theta^{(1)}_i, \theta^{(2)}_i \right) \), consider the marginalization over \( H_2 \):

\[
\int_{H_2} \text{DPM}(\theta_1 \in S_1 \times \Theta_2, \ldots, \theta_n \in S_n \times \Theta_2 | \alpha, H^*) \mu(H_2)
\]

\[
= \int_{\Sigma_2} \text{DPM}(\theta^{(1)}_1 \in S_1, \ldots, \theta^{(1)}_n \in S_n | \alpha, H_1) \int_{\Sigma_2} \mu(H_2)
\]

\[
= \text{DPM}(\theta^{(1)}_1 \in S_1, \ldots, \theta^{(1)}_n \in S_n | \alpha, H_1) \int_{\Sigma_2} \mu(H_2)
\]

When \( H_1 \) is random and \( H_2 \) is fixed. Let \( \lambda(\cdot) \) be a prior probability measure for \( H_1 \), i.e., \( H_1 \sim \lambda(\cdot) \). It is clear that Proposition 7 holds for each draw \( H_1 \) from \( \lambda(\cdot) \). This complete our proof.

**A.1.3. ADDITIONAL RESULT FOR CORRELATION ANALYSIS IN nDPM**

We now consider the correlation between \( \varphi_{ik} \) and \( \varphi_{jk'} \) for arbitrary \( i, j, k \) and \( k' \), i.e., we need to evaluate:

\[
P(\varphi_{ik} \in A_1, \varphi_{jk'} \in A_2 | \alpha, \eta, v, S)
\]

for two measurable sets \( A_1, A_2 \in \Sigma \) by integrating out over all immediate random measures. We use an explicit stick-breaking representation for \( U \) where \( U \sim \text{DP}(\alpha \text{DP}(vQ_0)) \) as follows

\[
U = \sum_{k=1}^{\infty} \pi_k \delta_{Q_k^*} \quad (8)
\]

where \( \pi \sim \text{GEM}(\alpha) \) and \( Q_k^* \overset{\text{iid}}{\sim} \text{DP}(vQ_0) \). We use the notation \( \delta_{Q_k^*} \) to denote the atomic measure on measure, placing its mass at measure \( Q_k^* \).

For \( i = j \), we have:

\[
P(\varphi_{ik} \in A_1, \varphi_{jk'} \in A_2 | Q_1, \ldots, Q_J) = Q_i(A_1)Q_i(A_2)
\]

Sequentially take expectation over \( Q_i \) and \( U \):

\[
\left( \int_{Q_i} Q_i(A_1)Q_i(A_2) dU (Q_i) \right) = \int_{Q_i} \sum_{k=1}^{\infty} \pi_k Q_k^*(A_1)Q_k^*(A_2)
\]

\[
= \sum_{k} \pi_k \left[ \sum_{k} Q_k^*(A_1)Q_k^*(A_2) \right]
\]

\[
\sum_{k} \sum_{k} \pi_k \left[ \sum_{k} Q_k^*(A_1)Q_k^*(A_2) \right]
\]

\[
Q_0(A_1 \cap A_2) + Q_0(A_1)Q_0(A_2)
\]

\[
\int_{v(v+1)} Q_0(A_1 \cap A_2) + Q_0(A_1)Q_0(A_2)
\]

Integrating \( Q_0 \sim \text{DP}(vS) \) we get:
For $i \neq j$, since $Q_i$ and $Q_j$ are conditionally independent given $U$, we get:

$$P(\varphi_{ik} \in A_1, \varphi_{jk'} \in A_2 \mid Q_0) =$$

$$= \frac{1}{v(v+1)} \left\{ \frac{Q_0(A_1 \cap A_2) + Q_0(A_1) Q_0(A_2)}{v(v+1)} \right\}$$

where

$$A = E[a_kb_k]$$

$$= E[Q_k^*(A_1) Q_k^*(A_2)]$$

$$= \frac{Q_0(A_1 \cap A_2) + Q_0(A_1) Q_0(A_2)}{v(v+1)}$$

and since $Q_k^*$ are iid draw from $DP(vQ_0)$ we have:

$$B = E[a_kb_k']$$

$$= E[Q_k^*(A_1) Q_k^*(A_2)]$$

$$= E[Q_k^*(A_1)] E[Q_k^*(A_2)]$$

$$= Q_0(A_1) Q_0(A_2)$$

Lastly, since $(\pi_1, \pi_2, \ldots) \sim GEM(\alpha)$, using the property of its stick-breaking representation $\sum_k \pi_k = \frac{1}{1 + \alpha}$. Put things together we obtain the expression for the correlation of $\varphi_{ik}$ and $\varphi_{jk'}$ for $i \neq j$ conditional on $Q_0$ as:

$$= \frac{1}{v(v+1)} \left\{ \frac{Q_0(A_1 \cap A_2) + Q_0(A_1) Q_0(A_2)}{v(v+1)} \frac{1}{1 + \alpha} Q_0(A_1) Q_0(A_2) \right\}$$

Next, integrating out $Q_0 \sim DP(vS)$ we get:

$$P(\varphi_{ik} \in A_1, \varphi_{jk'} \in A_2 \mid \alpha, v, \eta, S) =$$

$$= \frac{\alpha v(v+1) + 1}{(1 + \alpha) v(v+1)} E[Q_0(A_1) Q_0(A_2)]$$

$$+ \frac{\alpha v(v+1)}{(1 + \alpha) v(v+1)} E[Q_0(A_1 \cap A_2)]$$

$$= \frac{\alpha v(v+1)}{(1 + \alpha) v(v+1)} \frac{S(A_1 \cap A_2) + S(A_1) S(A_2)}{\eta(\eta+1)}$$

A.2. Model Inference Derivations

We provide detailed derivations for model inference with the graphical model displayed in Fig 1. The variables $\phi_k$, $\psi_m$, $\pi$, $\tau_k$ are integrated out due to conjugacy property. We need to sample these latent variables $z$, $l$, $\epsilon$ and hyper parameters $\alpha$, $v$, $\eta$. For convenience of notation, we denote $z_{-j}$ is a set of latent context variable $z$ in all documents excluding document $j$, $l_{j*}$ is all of hidden variables $l_{ji}$ in document $j$, and $l_{-j*}$ is all of $l$ in other documents rather than document $j$-th.

**Sampling $z$**

Sampling context index $z_j$ needs to take into account the influence of the corresponding context topics:

$$p(z_j = k \mid z_{-j}, l, x, \alpha, H) \propto p(z_j = k \mid z_{-j}, \alpha)$$

$$\text{CRP for context topic}$$

$$\times p(x_j \mid z_j = k, z_{-j}, x_{-j}, H)$$

$$\text{context predictive likelihood}$$

$$\times p(l_{j*} \mid z_j = k, l_{j*}, z_{-j}, \epsilon, v)$$

$$\text{content latent marginal likelihood}$$
The first term can easily be recognized as a form of Chinese Restaurant Process (CRP):

\[ p(z_j = k | z_{-j}, \alpha) = \begin{cases} \frac{n^k_{-j} + \alpha}{n^*_{-j} + \alpha} & \text{if } k \text{ old} \\ \frac{\alpha}{n^*_{-j} + \alpha} & \text{if } k \text{ knew} \end{cases} \]

where \( n^k_{-j} \) is the number of data \( z_j = k \) excluding \( z_j \), and \( n^*_{-j} \) is the count of all \( z \), except \( z_j \).

The second expression is the predictive likelihood from the context observations under the context component \( \phi_k \). Specifically, let \( f(\cdot \mid \phi) \) and \( h(\cdot) \) be respectively the density function for \( F(\phi) \) and \( H \), the conjugacy between \( F \) and \( H \) allows us to integrate out the mixture component parameter \( \phi_k \), leaving us the conditional density of \( x_j \) under the mixture component \( k \) given all the context data items exclude \( x_j \):

\[
p(x_j \mid z_j = k, z_{-j}, x_{-j}, H) = \frac{\int_{\phi_k} f(x_j \mid \phi_k) \prod_{j' \neq j, z_{j'} = k} f(x_{j'} \mid \phi_k) h(\phi_k) d\phi_k}{\int_{\phi_k} \prod_{j' \neq j, z_{j'} = k} f(x_{j'} \mid \phi_k) h(\phi_k) d\phi_k} = f^k_{x_j}(x_j)
\]

Finally, the last term is the contribution from the multiple latent variables of corresponding topics to that context. Since \( l_{j_i} \mid z_i = k \overset{i.d.}{\sim} \text{Mult} (\tau_k) \) where \( \tau_k \sim \text{Dir}(\nu_{e1}, \ldots, \nu_{eM}, \nu_{\text{new}}) \), we shall attempt to integrate out \( \tau_k \). Using the Multinomial-Dirichlet conjugacy property we proceed to compute the last term in Eq (9) as following:

\[
p(l_{j*} \mid z_j = k, z_{-j}, l_{-j*}, \epsilon, v) = \int_{\tau_k} p(l_{j*} \mid \tau_k) \times p(\tau_k \mid l_{j*} \mid z_j = k, j' \neq j, \epsilon, v) d\tau_k \\
\]

Recognizing the term \( p(\tau_k \mid l_{j*} \mid z_j = k, j' \neq j, \epsilon, v) \) is a posterior density, it is Dirichlet-distributed with the updated parameters

\[
p(\tau_k \mid l_{j*} \mid z_j = k, j' \neq j) = \text{Dir}(\nu_{e1} + c_{k,1}^{-j}, \ldots, \nu_{eM} + c_{k,M}^{-j}, \nu_{\text{new}})
\]

where \( c_{k,m} = \sum_{j' \neq j} \sum_{i=1}^{N_j} \mathbb{I}(l_{j'i} = m, z_{j'i} = k) \) is the count of topic \( m \) being assigned to context \( k \) excluding document \( j \). Using this result, \( p(l_{j*} \mid \tau_k) \) is a predictive likelihood for \( l_{j*} \) under the posterior Dirichlet parameters \( \tau_k \) in Eq 11 and therefore can be evaluated to be:

\[
p(l_{j*} \mid z_j = k, z_{-j}, l_{-j*}, \epsilon, v) = \int_{\tau_k} p(l_{j*} \mid \tau_k) \times \text{Dir}(\nu_{e1} + c_{k,1}^{-j}, \ldots, \nu_{eM} + c_{k,M}^{-j}, \nu_{\text{new}}) d\tau_k \\
= \prod_{m=1}^{M} \frac{\Gamma(\sum_{m=1}^{M} \nu_{e_m} + c_{k,m}^{-j})}{\prod_{m=1}^{M} \Gamma(\nu_{e_m} + c_{k,m}^{-j})} \\
\]

where \( c_{k,m} = \sum_{j' \neq j} \sum_{i=1}^{N_j} \mathbb{I}(l_{j'i} = m, z_{j'i} = k) \) is the count of topic \( m \) being assigned to context \( k \) excluding document \( j \). Using this result, \( p(l_{j*} \mid \tau_k) \) is a predictive likelihood for \( l_{j*} \) under the posterior Dirichlet parameters \( \tau_k \) in Eq 11 and therefore can be evaluated to be:

Note that \( \epsilon = (\epsilon_1, \epsilon_2, \ldots, \epsilon_M, \nu_{\text{new}}) \), here \( \epsilon_{1:M} = (\epsilon_1, \epsilon_2, \ldots, \epsilon_M) \), when sampling \( z_j \) we only use \( M \) active components from the previous iteration. In summary, the conditional distribution to sample \( z_j \) is given as:

\[
p(z_j = k \mid z_{-j}, l, x, \alpha, H) \propto \begin{cases} n_{-j}^k \times f^{-x_j}_{k}(x_j) \times A & \text{if } k \text{ previously used} \\ \alpha \times f^{-x_j}_{\text{new}}(x_j) \times B & \text{if } k = k_{\text{new}} \end{cases}
\]

Implementation note: to evaluate A and B, we make use of the marginal likelihood resulted from a Multinomial-Dirichlet conjugacy.
**Bayesian Nonparametric Multilevel Clustering with Group-Level Contexts**

**Sampling \( l \)**

Let \( w_{-j_i} \) be the same set as \( w \) excluding \( w_{ji}, \) i.e. \( w_{-j_i} = \{ w_{uv} : u \neq j \land v \neq i \} \), then we can write

\[
p(l_{ji} = m \mid l_{-ji}, z_j = k, v, w, S) \propto \frac{p(w_{ji} \mid w_{-j_i}, l_{ji} = m, \rho) \times p(l_{ji} = m \mid l_{-ji}, z_j = k, \epsilon_m, v)}{p(w_{ji} \mid l_{-ji}, z_j = k, \epsilon_m, v)}
\]

(12)

The first argument is computed as log likelihood predictive of the content with the component \( \psi_m \)

\[
p(w_{ji} \mid w_{-j_i}, l_{ji} = m, \rho) = \int_{\lambda_m} s(w_{ji} \mid \lambda_m) \left[ \prod_{u \in w_{-j_i}(m)} y(u \mid \lambda_m) \right] s(\lambda_m) d\lambda_m
\]

(13)

And the second term is inspired by Chinese Restaurant Franchise (CRF) as:

\[
p(l_{ji} = m \mid l_{-ji}, \epsilon_m, v) = \left\{ \begin{array}{ll} c_{k,m} + v \epsilon_m & \text{if mold} \\ \epsilon_{\text{new}} & \text{if new} \end{array} \right.
\]

(14)

where \( c_{k,m} \) is the number of data point \( \{l_{ji} \mid l_{ji} = m, z_j = k, 1 \leq j \leq J, 1 \leq i \leq N_j\} \). The final form to sample \( l_{ji} \) is given as:

\[
p(l_{ji} = m \mid l_{-ji}, z_j = k, w, v, \epsilon) \propto \left\{ \begin{array}{ll} (c_{k,m} + v \epsilon_m) \times y_m^{-w_{ji}} (w_{ji}) & \text{if m used previously} \\ \epsilon_{\text{new}} \times y_m^{-w_{ji}} (w_{ji}) & \text{if m = m}_{\text{new}} \end{array} \right.
\]

**Sampling \( \epsilon \)**

Note that sampling \( \epsilon \) require both \( z \) and \( l \).

\[
p(\epsilon \mid l, z, v, \eta) \propto p(\epsilon \mid l, v, z, \eta) \propto p(\epsilon) \propto \eta^{\epsilon_{\text{new}} - 1} \Gamma(\epsilon_{\text{new}}) \prod_{k=1}^{K} \Gamma(v + \eta_{k} + n_{k})
\]

(15)

Isolating the content variables \( l_{k}^{i} \) generated by the same context \( z_j = k \) into one group:

\[
l_{k}^{i} = \{ l_{ji} : 1 \leq i \leq N_j, z_j = k \} \}
\]

The first term of 15 can be expressed following:

\[
p(l \mid \epsilon, v, z, \eta) = \prod_{k=1}^{K} \int \tau_k \rho(l_{*k} \mid \tau_k) p(\tau_k \mid \epsilon) d\tau_k
\]

\[
= \frac{\Gamma(v) \prod_{m=1}^{M} \Gamma(v_{\text{new}} + n_{km})}{\Gamma(v_{\text{new}})}
\]

where \( n_{k} = \{ w_{ji} \mid z_j = k, i = 1, \ldots, N_j \} \) and \( n_{km} = \{ w_{ji} \mid z_j = k, l_{ji} = m, 1 \leq j \leq J, 1 \leq i \leq N_j \} \).

Let \( \eta_{r} = \frac{n_r}{M}, \eta_{\text{new}} = \frac{R - M \eta_r}{M} \) and recall that \( \epsilon \sim \text{Dir}(\eta_{1}, \ldots, \eta_{r}, \eta_{\text{new}}) \), the last term of Eq 15 is a Dirichlet density:

\[
p(\epsilon \mid \eta) = \text{Dir} \left( \frac{\eta_1, \eta_2, \ldots, \eta_M, \eta_{\text{new}}}{M} \right)
\]

Using the result:

\[
\frac{\Gamma(\epsilon_{\text{new}} + n_{km})}{\Gamma(\epsilon_{\text{new}})} = \sum_{o_{km}=0}^{n_{km}} \text{Stirl}(o_{km}, n_{km}) (v_{\epsilon_m})^{o_{km}}
\]

Thus, Eq 15 becomes:

\[
p(l \mid \epsilon, o, l, z, v, \eta) \propto \prod_{k=1}^{K} \Gamma(v) \prod_{m=1}^{M} \Gamma(v + n_{km})
\]

\[
= \epsilon_{\text{new}}^{\epsilon_{\text{new}} - 1} \prod_{o_{km}=0}^{n_{km}} \text{Stirl}(o_{km}, n_{km}) (v_{\epsilon_m})^{o_{km}}
\]

\[
p(\epsilon, o \mid l, z, v, \eta) \propto \prod_{k=1}^{K} \Gamma(v) \prod_{m=1}^{M} \Gamma(v + n_{km})
\]

\[
= \epsilon_{\text{new}}^{\epsilon_{\text{new}} - 1} \prod_{o_{km}=0}^{n_{km}} \text{Stirl}(o_{km}, n_{km}) (v_{\epsilon_m})^{o_{km}}
\]

The probability of the auxiliary variable \( o_{km} \) is computed as:

\[
p(o_{km}) = \sum_{o_{km}=0}^{n_{km}} \text{Stirl}(o_{km}, n_{km}) (v_{\epsilon_m})^{o_{km}}
\]

Now let \( o = (o_{km} : \forall k, m) \) we derive the following joint distribution:

\[
p(\epsilon \mid o, l, z, v, \eta) = \epsilon_{\text{new}}^{\epsilon_{\text{new}} - 1} \prod_{m=1}^{M} \sum_{o_{km}=0}^{n_{km}} o_{km} (v_{\epsilon_m})^{o_{km}}
\]
As $R \to \infty$, we have

$$p(\epsilon \mid \alpha, l, z, v, \eta) \propto \epsilon_{\text{new}}^{-\frac{1}{2}} \prod_{m=1}^{M} \epsilon_{\sum K}^{o_{km} - 1}$$

Finally, we sample $\epsilon$ jointly with the auxiliary variable $o_{km}$ by:

$$p(o_{km} = h \mid \cdot) \propto \text{Stirl}(h, n_{km})(ve_m)^h, h = 0, 1, \ldots, n_{km}$$

$$p(\epsilon) \propto \epsilon_{\text{new}}^{-\frac{1}{2}} \prod_{m=1}^{M} \epsilon_{\sum K}^{o_{km} - 1}$$

**Sampling hyperparameters**

In the proposed model, there are three hyper-parameters which need to be sampled: $\alpha, v$ and $\eta$.

**Sampling $\eta$**

Using similar strategy and using technique from Escobar and West (Escobar & West, 1995), we have

$$p(M \mid \eta, u) = \text{Stirl}(M, u) \eta^M \frac{\Gamma(\eta)}{\Gamma(\eta + u)}$$

where $u = \sum_m u_m$ with $u_m = \sum_K o_{km}$ in the previous sampling $\epsilon$ and $M$ is the number of active content atoms. Let $\eta \sim \text{Gamma}(\eta_1, \eta_2)$. Recall that:

$$\frac{\Gamma(\eta)}{\Gamma(\eta + u)} = \int_0^1 t^\eta (1 - t)^{u-1} \left(1 + \frac{u}{\eta}\right) dt$$

that we have just introduced an auxiliary variable $t$

$$p(t \mid \eta) \propto t^\eta (1 - t)^{u-1} = \text{Beta}(\eta + 1, u)$$

Therefore,

$$p(\eta \mid t) \propto \eta^{\eta_1 - 1 + M} \exp \{-\eta_2\} \times t^\eta (1 - t)^{u-1} \left(1 + \frac{u}{\eta}\right)$$

$$= \eta^{\eta_1 - 1 + M} \times \exp \{-\eta_2 - \log t\} \times (1 - t)^{u-1} \times (1 - \pi_t) \text{Gamma}(\eta_1 + M, \eta_2 - \log t) + (1 - \pi_t) \text{Gamma}(\eta_1 + M - 1, \eta_2 - \log t)$$

where $\pi_t$ satisfies this following equation to make the above expression a proper mixture density:

$$\frac{\pi_t}{\pi_t + \frac{\eta_1 + M - 1}{u(\eta_2 - \log t)}}$$

To re-sample $\eta$, we first sample $t \sim \text{Beta}(\eta + 1, u)$, compute $\pi_t$ as in equation 17, and then use $\pi_t$ to select the correct Gamma distribution to sample $\eta$ as in Eq. 16.

**Sampling $\alpha$**

Again sampling $\alpha$ is similar to Escobar et al (Escobar & West, 1995). Assuming $\alpha \sim \text{Gamma}(\alpha_1, \alpha_2)$ with the auxiliary variable $t$:

$$p(t \mid K) \propto t^{\alpha_1} (1 - t)^{J-1}$$

$$p(t \mid \alpha, K) \propto \text{Beta}(\alpha_1 + 1, J)$$

$J$: number of document

$$p(\eta \mid t, K) \sim \pi_t \text{Gamma}(\alpha_1 + K, \alpha_2 - \log(t))$$

$$+ (1 - \pi_t) \text{Gamma}(\alpha_1 + K - 1, \alpha_2 - \log(t))$$

where $c, d$ are prior parameter for sampling $\eta$ following Gamma distribution and $\int_{\text{new}}^{-1} = \frac{\alpha_1 + K - 1}{d - \log(t)}$

**Sampling $v$**

Sampling $v$ is similar to sampling concentration parameter in HDP (Teh et al., 2006b). Denote $o_{ks} = \sum_m o_{km}$ where $o_{km}$ is defined previously during the sampling step for $\epsilon$, $n_{ks} = \sum_m n_{km}$, where $n_{km}$ is the count of $|\{l_{ji} \mid z_{ji} = k, l_{ji} = m\}|$. Using similar technique in (Teh et al., 2006b), we write:

$$p(o_{1s}, o_{2s}, \ldots, o_{Ks} \mid v, n_{1s}, \ldots, n_{Ks}) = \prod_{k=1}^{K} \text{Stirl}(n_{ks}, o_{ks}) \alpha_0^{o_{ks}}$$

where the last term can be expressed as

$$\frac{\Gamma(v)}{\Gamma(v + n_{ks})} = \frac{1}{\Gamma(n_{ks})} \int_0^1 b_k^{n_{ks} - 1} \left(1 + \frac{n_{ks}}{v}\right) db_k$$

Assuming $v \sim \text{Gamma}(v_1, v_2)$, define the auxiliary variables $b = \{b_k \mid k = 1, \ldots, K\}, b_k \in [0, 1]$ and $t = \{t_k \mid k = 1, \ldots, K\}, t_k \in [0, 1]$ we have
\[
q(v, b, t) \propto v^{v_1-1 + \sum_k M_k} \exp \{-vv_1\} \\
\times \prod_{k=1}^{K} b_k^v (1 - b_k)^{M_k - 1} \left( \frac{M_k}{v} \right)^{t_k}
\]

We will sample the auxiliary variables \(b_k, t_k\) in accordance with \(v\) that are defined below:

\[
q(b_k \mid v) = \text{Beta} (v + 1, o_{k^*})
\]
\[
q(t_k \mid .) = \text{Bernoulli} \left( \frac{o_{k^*}/v}{1 + o_{k^*}/v} \right)
\]
\[
q(v \mid .) = \text{Gamma} \left( v_1 + \sum_k (o_{k^*} - t_k), v_2 - \sum_k \log b_k \right)
\]

### A.3. Relative Roles of Context and Content Data

Regarding the inference of the cluster index \(z_j\) (Eq. 9), to obtain the marginal likelihood (the third term in Eq. 9) one has to integrate out the words’ topic labels \(l_{ji}\). In doing so, it can be shown that the sufficient statistics coming from the content data toward the inference of the topic frequencies and the clustering labels will just be the empirical word frequency from each document. As each document becomes sufficiently long, the empirical word frequency quickly concentrates around its mean by the central limit theorem (CLT), so as soon as the effect of CLT kicks in, increasing document length further will do very little in improving this sufficient statistics.

Increasing the document length will probably not hurt, of course. But to what extent it contributes relative to the number of documents awaits a longer and richer story to be told.

We confirm this argument by varying the document length and the number of documents in the synthetic document and see how they affect the posterior of the clustering labels. Each experiment is repeated 20 times. We record the mean and standard deviation of the clustering performance by NMI score. As can be seen from Fig 7, using context observation makes the model more robust in recovering the true document clusters.

### A.4. Perplexity Evaluation

The standard perplexity proposed by Blei et al (Blei et al., 2003), used to evaluate the proposed model as following:

\[
\text{perplexity} (w_{\text{Test}}) = \exp \left\{ \frac{-\sum_{j=1}^{J_{\text{test}}} \log p (w_{j\text{Test}})}{\sum_{j=1}^{J_{\text{test}}} N_{j\text{Test}}} \right\}
\]

During individual sampling iteration \(t\), we utilize the important sampling approach (Teh et al., 2006a) to compute \(p (w_{\text{Test}})\). The posterior estimation of \(\psi_m\) in a Multinomial-Dirichlet case is defined below, note that it can be in other types of conjugacies (Gelman et al., 2003) (e.g. Gaussian-Wishart, Binomial-Poisson):

\[
\psi_{m,v}^t = \frac{n_{m,v}^t + \text{smooth}}{\sum_{v=1}^V n_{m,v}^t + V \times \text{smooth}}
\]

\[
\tau_{k,m}^t = \frac{c_{k,m} + v \times \epsilon_m}{\sum_{m=1}^M (c_{k,m} + v \times \epsilon_m)}
\]

where \(n_{m,v}^t\) is number of times a word \(v, v \in \{1, ..., V\}\) is assigned to context topic \(\psi_m\) in iteration \(t\), and \(c_{k,m}\) is the count of the set \(\{w_{ji} \mid z_j = k, l_{ji} = m, 0 \leq j \leq J, 0 \leq i \leq N_j\}\). There is a constant smooth parameter (Asuncion et al., 2009) that influence on the count, roughly set as 0.1. Supposed that we estimate \(z_j^{\text{Test}} = k\) and \(l_{ji}^{\text{Test}} = m\), then the probability \(p (w_{j\text{Test}})\) is computed as:

\[
p (w_{j\text{Test}}) = \prod_{t=1}^{T} \frac{1}{T} \sum_{t=1}^{T} \tau_{k,m}^t \psi_{m,w_{j\text{Test}}}^t
\]

where \(T\) is the number of collected Gibbs samples.
Bayesian Nonparametric Multilevel Clustering with Group-Level Contexts

MC2 on Synthetic Data

J: number of document.
NJ: number of word per document.
NMI: normalized mutual information.

Note: Document clustering performance is evaluated on the estimated document cluster \( z_j \) vs their groundtruth.

Figure 7. Document clustering performance with different numbers of observed words and documents.
