Whitney’s Theorem, Triangular Sets and Probabilistic Descent on Manifolds

David W. Dreisigmeyer

Abstract We examine doing probabilistic descent over manifolds implicitly defined by a set of polynomials with rational coefficients. The system of polynomials is assumed to be triangularized. An application of Whitney’s embedding theorem allows us to work in a reduced dimensional embedding space. A numerical continuation method applied to the reduced-dimensional embedded manifold is used to drive the procedure.

1 Introduction

In an optimization problem with equality constraints the feasible set often has nice geometric properties. If we ‘stand’ at a typical point the feasible set will locally look to us like a Euclidean space. But this locally Euclidean space will be contained in a larger space. For example, the feasible set could be a one-dimensional string contained in a hundred-dimensional ambient space. It seems like a waste to work with a hundred variables when the geometric structure we’re actually interested in is only one-dimensional. Whitney’s theorem tells us that in fact we could work in a three-dimensional ambient space. The string can be projected from the original hundred dimensions into a random three-dimensional subspace. Provided we can find a map from the projected string

back to the original string we lose nothing by working in the three-dimensional space.

Sard’s theorem is well known in optimization since it tells us that equality constraints often give a reasonable feasible set over which we work. Or at least it will alert us when this may not be the case. Whitney’s theorem is perhaps less well known. The theorem offers a potentially large decrease in the effective dimension one needs to optimize in, which is certainly an attractive proposal. However this is not cost free. Firstly, the decrease in dimensionality is achieved by a linear projection from the initial ambient space into a lower-dimensional working space. This requires some sort of variable elimination from the set of equality constraints in order to do the projection. The variable elimination is the nonlinear analogue of triangularizing a matrix. Secondly, the reconstruction from the reduced dimension working space back into the original space is generally nonlinear. A numerical implementation of the inverse (implicit) function theorem over a manifold is required. This is a nonlinear version of basic and nonbasic variables. The manifold in the reduced dimensional space serves as the basic variables and the embedding in the higher dimensional space represents the nonbasic variables.

A decade ago the author was interested in applying Whitney’s theorem to optimization problems. Unfortunately the required machinery was not quite sufficient enough to give any satisfactory results. In the intervening years developments in polynomial decompositions over real numbers has made it possible to provide a sketch of the main ideas. While the method is not quite complete it is complete enough to offer some potential applications and, more importantly, a clear map of what work still needs to be done. In other words: it works but it may not yet work well enough.

The paper is organized as follows. We give a simple example in Section 2 that demonstrates the basic problem and principles we will be dealing with. Section 3 covers the necessary results from differential geometry. The main result is Whitney’s weak embedding theorem which gives an upper bound on the minimal embedding dimension of a manifold. In Section 4 we look at some needed results from real algebraic geometry. In particular some real polynomial decompositions are introduced. These put the constraint equations into a form convenient for applying Whitney’s theorem, which we examine in Section 5. Moving over manifolds in a controllable and intelligent way is necessary. Section 6 looks at some methods to accomplish this. The full optimization procedure is laid out in Section 7 with Section 8 providing an example. A discussion follows in Section 9.

2 Motivating Example

Here we give a simple example in order to motivate and demonstrate the methodology that will be developed. Consider the optimization problem

$$\min_{z \in \mathbb{R}^4} f(z)$$
subject to the constraints

\begin{align*}
0 &= G_1(z) = z_4 + z_3 + z_2 + z_1, \\
0 &= G_2(z) = z_4z_1 + z_4z_3 + z_3z_2 + z_2z_1, \\
0 &= G_3(z) = z_4z_2z_1 + z_4z_3z_1 + z_4z_3z_2 + z_3z_2z_1 \text{ and} \\
0 &= G_4(z) = z_4z_3z_2z_1 - 1.
\end{align*}

The constraint set can be rewritten in the form

\begin{align}
0 &= g_1(x, u) = u^2x^2 - 1 \\
0 &= g_2(y_1, u) = y_1 + u \\
0 &= g_3(y_2, x) = y_2 + x
\end{align}

(1)

where we renamed the variables \( u = z_1, x = z_2, y_1 = z_3 \) and \( y_2 = z_4 \). Looking at the polynomials in (1) we see that they are in a ‘triangular form’: \( g_i \) only depends on \( u \), \( x \) or \( y_j \) where \( j < i \).

Looking at the new polynomials we see that it is not necessary to work in \( \mathbb{R}^4 \). Only the \( (x, u) \in \mathbb{R}^2 \) need to be explicitly optimized over, treating \( y_1(x, u) = -u \) and \( y_2(x, u) = -x \) as functions of \( u \) and \( x \). The original optimization problem now becomes

\[
\min_{(x, u) \in \mathbb{R}^2} \hat{f}(y_1(x, u), y_2(x, u), x, u) \text{ subject to } g_1(x, u) = 0
\]

where \( \hat{f}(z_1, z_2, z_3, z_4) = \hat{f}(z_3, z_4, z_2, z_1) \). [We will typically drop the ‘hat’ notation on the objective function when the variables are simply permuted. The context should make it clear when this occurs.]

This example highlights the key techniques we will employ. First, we have an optimization problem initially formulated in a ‘large’ Euclidean space. The constraints are given by polynomials with rational coefficients. A triangular decomposition can be performed on the original constraint statements to derive a new set of constraints. This new constraint set is then used to reduce the effective dimension we need to optimize in. The optimization can now proceed in a lower-dimensional Euclidean space versus the original one. As part of the projection into the lower-dimensional space an inverse function is used to map from the feasible set in the lower dimension back to the original feasible set.

3 Whitney’s Theorem

A manifold \( \mathcal{M} \) is a subset of \( \mathbb{R}^n \) that looks locally like \( \mathbb{R}^m, n > m \). Let \( \mathcal{I} \) be an index set and for each \( i \in \mathcal{I} \) let \( V_i \subset \mathcal{M} \) be an open subset where \( \bigcup_{i \in \mathcal{I}} V_i = \mathcal{M} \). Additionally, let there be homeomorphisms \( \phi_i : V_i \to \mathbb{R}^m \). Each pair \( (V_i, \phi_i) \) is called a chart and the set \( \{(V_i, \phi_i)\}_{i \in \mathcal{I}} \) is called an atlas.

When two open subsets \( V_i \) and \( V_j \) of \( \mathcal{M} \) overlap there will be a homeomorphic transition function \( \tau_{ij} : \mathbb{R}^m \to \mathbb{R}^m \) on the overlap \( V_i \cap V_j \) defined by
The transition functions are often taken to be differentiable. In this case we have a differentiable manifold. If the \( \tau_{ij} \) are all \( C^k \), \( k \geq 1 \), then \( M \) is said to be a \( C^k \)-manifold. If \( M \) is a \( C^\infty \)-manifold then it is called smooth. Every \( C^k \)-manifold can be made smooth [2].

At every point \( p \in M \subset \mathbb{R}^n \) a tangent space \( T_pM \) can be attached. If an inner product \( h : T_pM \times T_pM \to \mathbb{R} \) is defined for every \( p \in M \) and varies smoothly over \( M \) then we have a Riemannian manifold. The function \( h(\cdot, \cdot) \) is called a metric and with it notions of lengths and angles in \( T_pM \) are available over \( M \).

The manifolds we consider arise from equality constraints. Definition 3.1 (Regular level sets) Let \( g : \mathbb{R}^{m+k} \to \mathbb{R}^k \). For the set \( M = \{z : g(z) = c\} \) assume \( \nabla g(z) \) is full rank. Then \( M \) is a regular level set of \( g(z) \). Additionally, the null space of \( \nabla g(z) \) coincides with the tangent space to \( M \). □

This paper will consider equality constraints given by members of \( \mathbb{Q}[z] \), the polynomials in \( z = [z_1, \ldots, z_{m+k}] \) with rational coefficients. Then by Sard’s theorem almost every level set is a Riemannian manifold.

Theorem 3.1 (Regular level set manifolds and Sard’s theorem [2]) Let \( g : \mathbb{R}^{m+k} \to \mathbb{R}^k \) be a \( C^\infty \) function. Then almost every level set of \( g(z) \) is regular and a \( m \)-dimensional manifold. A regular level set acquires a metric from its embedding in \( \mathbb{R}^{m+k} \) by restricting the standard Euclidean metric to the tangent space \( T_pM \) given by null(\( \nabla g(p) \)) for all \( p \in M \).

One issue is that the \( k \) in Theorem 3.1 may be much larger than \( m \). So even though the manifold may be low-dimensional it could be embedded in a very high-dimensional space. Whitney’s theorem gives an upper bound on the minimal embedding dimensional for any manifold.

Theorem 3.2 (Whitney’s weak embedding theorem [2]) Let \( M \) be an \( m \)-dimensional manifold. Then \( M \) can be embedded in \( \mathbb{R}^{2m+1} \). Further, if \( M \) is embedded in \( \mathbb{R}^{m+k} \), \( k > m+1 \), a random projection into a \( 2m+1 \) subspace gives an embedding of \( M \) in \( \mathbb{R}^{2m+1} \).

4 Triangular Sets

Here we cover the necessary background from real algebraic geometry. Our main focus is putting a set of polynomials \( P \subset \mathbb{Q}[z] \) into a convenient form for utilizing Whitney’s theorem.

Definition 4.1 (Semi-algebraic sets, real algebraic varieties and Nash manifolds) A set \( S \subset \mathbb{R}^n \) is a semi-algebraic set if it satisfies a set of polynomial equations \( g_i(z) = 0, i = 1, \ldots, j \), and polynomial strict inequalities \( h_i(z) > 0, i = 1, \ldots, l \), or a finite union of such sets. A real algebraic variety
is defined using only a set of polynomial equations \( g_i(z) = 0, \ i = 1, \ldots, j \), without finite unions. Nash manifolds are semi-algebraic sets that are also manifolds. □

This paper focuses on Nash manifolds that are also varieties.

In order to utilize Whitney’s theorem the polynomials defining a Nash manifold will need to be decomposed into a friendlier form. Let the Nash manifold \( \mathcal{N} \subset \mathbb{R}^{m+k} \) be defined by the set of polynomial equations \( g_i(z) = 0, \ i = 1, \ldots, k \). Assign to the entries of \( z \) the ordering 

\[
z_1 < z_2 < \ldots < z_{m+k}.
\]

Define \( Q_i = \mathbb{Q}[z_1, \ldots, z_i] \) as the ring of polynomials in the variables \( z_1, \ldots, z_i \) with rational coefficients. \( \deg(g, z_i) \) is the degree of polynomial \( g \) in the variable \( z_i \). \( mvar(g) \) is the greatest variable \( z_i \) such that \( \deg(g, z_i) \neq 0 \). We can decompose a \( g \in Q_i \) into the form \( g = \iota z^d + \tau \) where \( d = \deg(g, z_i) > 0 \), \( \iota \in Q_{i-1} \) and \( \tau \in Q_i \) with \( \deg(\tau, z_i) < d \). Then \( \text{init}(g) = \iota \) is the initial of \( g \), \( mdeg(g) = d \) is the main degree of \( g \), \( \text{rank}(g) = z^d_i \) is the rank of \( g \), \( \text{tail}(g) = \tau \) is the tail of \( g \) and \( \text{head}(g) = g - \text{tail}(g) = iz^d_i \) is the head of \( g \).

Every polynomial is then decomposed as \( p = \text{init}(p)\text{rank}(p) + \text{tail}(p) \).

**Definition 4.2 (Triangular sets)** Let \( T \subset Q_n \). We call \( T \) a triangular set if no member of \( T \) is constant and for any pair \( g, h \in T \), \( g \neq h \), we have \( mvar(g) \neq mvar(h) \). If \( z_i = mvar(g) \) for some \( g \in T \) then \( z_i \) is called algebraic with respect to \( T \). Otherwise \( z_i \) is called free with respect to \( T \). □

Triangular sets are a nonlinear generalization of triangulating a matrix. They are very convenient for using Whitney’s theorem.

**Example 4.1** Let \( T = \{ z_1^2 z_2 - 1, z_3 + z_1, z_4 + z_2 \} \). This is a triangular set where

\[
mvar(z_1^2 z_2^2 - 1) = z_2,
mvar(z_3 + z_1) = z_3 \text{ and } mvar(z_4 + z_2) = z_4.
\]

Then \( z_1 \) is free and the other variables are algebraic. □
Definition 4.3 (Saturated ideals) Given a triangular set \( T = \{t_1, \ldots, t_k\} \) the ideal \( \langle T \rangle \) generated by \( T \) is given by
\[
\langle T \rangle = \{ q \in \mathbb{Q}[z] : q = \sum_i p_i t_i, \ p_i \in \mathbb{Q}[z] \}.
\]
Let \( h_T = \prod_i \text{init}(t_i) \). The saturated ideal of \( T \) is defined as
\[
\text{sat}(T) = \{ q \in \mathbb{Q}[z] : \exists n \in \mathbb{N}_0 \text{ such that } h_T^n q \in \langle T \rangle \}
\]
with \( \text{sat}(\emptyset) = \{0\} \).

The ideal \( \langle T \rangle \) gives all valid equality constraints that follow from those in \( T \). We see that \( \langle T \rangle \subset \text{sat}(T) \) but \( \text{sat}(T) \) can contain additional polynomials.

Definition 4.4 (Regular chains) Let \( T = \{t_1, \ldots, t_k\} \) be a triangular set. A \( p \in \mathbb{Q}[z] \) is regular modulo \( \text{sat}(T) \) if \( p \notin \text{sat}(T) \) and there does not exist a \( q \in \mathbb{Q}[z] \) where \( q \notin \text{sat}(T) \) but \( pq \in \text{sat}(T) \). Define \( T_{\leq j} = \{t_1, \ldots, t_{j-1}\} \), \( j < k \). \( T \) is a regular chain if \( T = \emptyset \), or \( T_{< k} \) is a regular chain and \( \text{init}(t_k) \) is regular modulo \( \text{sat}(T_{< k}) \).

Definition 4.5 (Kalkbrener triangular decomposition [4]) Let \( T = \{T_1, \ldots, T_i\} \) be a set of regular chains and \( V(F) \) be an algebraic variety. \( T \) is a Kalkbrener triangular decomposition of \( V(F) \) if \( V(F) = \bigcup_i V(\text{sat}(T_i)) \).

So \( V(\text{sat}(T_i)) \) is geometrically more relevant to Kalkbrener’s method than \( V(T_i) \): each \( V(\text{sat}(T_i)) \) gives some piece of \( V(F) \). We can relate \( V(T) \) and \( V(\text{sat}(T)) \).

Definition 4.6 (Regular zeros) Given a triangular set \( T = \{t_1, \ldots, t_k\} \) let \( h_T = \prod_i \text{init}(t_i) \). The regular zeros \( W(T) \) of the triangular set \( T \) is defined as \( W(T) = V(T) - V(h_T) \).

For a triangular set \( T \) it is the case that [7]
\[
V(\text{sat}(T)) = \overline{W(T)}
\]
where closure is with respect to the Zariski topology. If \( V(T) \) is also a manifold then \( \overline{W(T)} = V(T) = V(\text{sat}(T)) \).

Definition 4.7 (Radical of \( \langle T \rangle \)) The radical of the ideal \( \langle T \rangle \) is
\[
\sqrt{\langle T \rangle} = \{ q \in \mathbb{Q}[z] : \exists n \in \mathbb{N}_0 \text{ such that } q^n \in \langle T \rangle \}.
\]
That is, \( \sqrt{\langle T \rangle} \) consists of all those polynomials that vanish on \( V(T) \).

Since \( V(T) = V(\text{sat}(T)) \) it follows from Hilbert’s Nullstellensatz [8] that
\[
\sqrt{\langle T \rangle} = \sqrt{\text{sat}(T)}.
\]
From this we see that a Kalkbrener triangular decomposition \( T = \{T_1, \ldots, T_i\} \) of \( F \subset \mathbb{Q}[z] \) gives
\[
\sqrt{\langle T \rangle} = \bigcap_i \sqrt{\text{sat}(T_i)}.
\]
A Kalkbrener triangular decomposition allows for complex solutions but Nash manifolds only work with the real solutions.
5 Whitney’s Theorem Applied to Triangular Sets

We first look at an easy to understand case. Consider the linear system $Az = b$. This set of polynomials defines a special type of manifold that is globally like $\mathbb{R}^m$ when $A \in \mathbb{R}^{k \times (m+k)}$. Let $k > m + 1$ for what follows. It is convenient to have $A$ in a triangular form

$$A = \begin{bmatrix} k - m - 1 & m + 1 & m \\ A_{11} & A_{12} & A_{13} \\ 0 & A_{22} & A_{23} \end{bmatrix}^{k - m - 1} \begin{bmatrix} m + 1 \\ A_{11} & A_{12} & A_{13} \\ 0 & A_{22} & A_{23} \end{bmatrix}$$

with $A_{11}$ and $A_{22}$ upper triangular. Partition the $z$ as

$$z = [y \ x \ u]$$

with $y \in \mathbb{R}^{k - m - 1}$, $x \in \mathbb{R}^{m+1}$ and $u \in \mathbb{R}^m$. Whitney’s theorem tells us that the space given by $x$ and $u$ is sufficient to embed the manifold implicitly defined by the set of polynomials $Az - b$. Let the original manifold defined in $\mathbb{R}^m$ be denoted by $M$ and the projected image in $\mathbb{R}^{2m+1}$ be denoted by $M'$. Partition $b$ as $b = [b_1 \ b_2]$. We can solve the equation

$$[A_{22} \ A_{23}] \begin{bmatrix} x \\ u \end{bmatrix} = b_2$$

to find the points on $M'$. Call one of these $[x^* \ u^*]^T \in M'$. This can then be mapped onto the corresponding point on $M$ by solving

$$[A_{11} \ A_{12} \ A_{13}] \begin{bmatrix} y \\ x^* \\ u^* \end{bmatrix} = b_1$$

for $y$. While we may not want to do it in this case, the optimization can be carried out in $\mathbb{R}^{2m+1}$ and we can then map from $M'$ to $M$ by finding $y = y(x, u)$. Using the full vector $z = [y \ x \ u]$ we can pull back any function defined on $M$ to $M'$. A function that is pulled back could be, e.g., the objective function or an inequality constraint.

Now we can repeat the above example for the general nonlinear case. We will make the simplifying assumption that $M$ is path connected. If there are multiple pieces of $M$ then the following argument still carries through for each individual piece. After a possible reordering of the coordinates, partition the $z \in \mathbb{R}^{m+k}$ from Definition 3.1 as

$$z = [y \ x \ u]$$

where $y \in \mathbb{R}^{k-m-1}$, $x \in \mathbb{R}^{m+1}$ and $u \in \mathbb{R}^m$. We take the members of $g(z)$ to be triangularized \[4\] in the $x$ and $y$ as

$$g^*(x, u) : \mathbb{R}^{2m+1} \rightarrow \mathbb{R}^{m+1} \text{ where}$$

$$g_i^*(x, u) = g_i^*(x_1, \ldots, x_i, u) \quad (2a)$$

$$g^*(x, u) = [g_1^*, \ldots, g_{m+1}^*]^T \quad (2b)$$
for \( i = 1, \ldots, m + 1 \) and
\[
g^2(y; x, u) : \mathbb{R}^{k-m-1} \to \mathbb{R}^{k-m-1} \text{ where} \tag{2c}
g_j^2(y; x, u) = g_j^2(y_1, \ldots, y_j; x, u) \tag{2d}
\]
for \( j = 1, \ldots, k-m-1 \), with \( g = [g^* \, g^c]^T \). In (2c) the \( x \) and \( u \) are determined from (2a) and are treated as parameters. If there is at most one solution to \( g^*(y; x, u) = 0 \) for every \( x \) and \( u \) such that \( g^*(x, u) = 0 \), then \( g^*(x, u) \) gives a low-dimensional embedding of our manifold. Theorem 3.2 tells us that typically any choice for the \( x \) and \( u \) should accomplish this.

We see that the optimization can progress in \( \mathbb{R}^{2m+1} \) by using the \( x \) and \( u \) variables. The manifold defined implicitly by (2a) can then be mapped onto the original manifold by solving (2c) for the unique \( y(x, u) \). We then use
\[
z(u, x) = [y(x, u) \times u]
\]
to pull back the objective function and any inequality constraints from the manifold embedding in \( \mathbb{R}^{m+k} \) to the embedding in \( \mathbb{R}^{2m+1} \).

The ability to triangularize the polynomials in \( g(z) \) is what allows Whitney’s theorem to be easily implemented. There are two things to notice about this triangularization. First, all of this is restricted to working only with the real versus complex roots. Second, as noted above, we only work on the highest dimensional subcomponent of the variety \( V(g) \).

Finding the function \( y(x, u) \) is the crucial step. The most obvious way of doing this is the one we presented above. However it’s unimportant how this is done in practice. Any numerical implementation of the implicit function theorem applied to \( g^2(y, x, u) \) will suffice, where now \( x \) and \( u \) are treated as variables.

6 Moving Over the Manifold

We will need a procedure to intelligently move over the manifold \( M' \subset \mathbb{R}^{2m+1} \). One advantage of working with a lower-dimensional embedding space is that methods that may be expensive when working in high-dimensions can become feasible. This is counter-balanced by the need to map back into the original space, say with the \( y(x, u) \) from Section 4. But we’re free to use different methods to accomplish these different goals. We move along a path on the manifold \( M' \) with one technique and drag along a point on \( M \subset \mathbb{R}^{m+k} \) with a different one. Numerical continuation methods will likely play a key roll in any implementation employing Whitney’s theorem. We mention the references [9–11] in addition to the ones below.

On a Riemannian manifold \( M \) a geodesic is the shortest path between two (nearby) points on \( M \) and generalizes the notion of a straight line. The
coupled nonlinear equations for a geodesic on $M$ are
\[ z^i + \Gamma^i_{jk} \dot{z}^j \dot{z}^k = 0 \]
where $[\nabla g^+]^i$ is the $i$-th row of the pseudo-inverse of $\nabla g$. The Einstein summation convention is used above where a repeated index in a term is summed over. The $\Gamma^i_{jk}$ are the Christoffel symbols associated with $g$. The distance moved over the manifold in a unit time period is controlled by the length of the initial tangent vector $\dot{z}_0$. For $M' \subset \mathbb{R}^{2m+1}$ $g^*$ is substituted for $g$ and we only work with the $x$ and $u$ variables. If $2m + 1$ is ‘small’ it’s possible that finding geodesics on $M'$ would be feasible. One could then find $y(x, u)$ for the end point of a geodesic and use this to pull back any necessary functions from $M$ to $M'$.

In [13] a method of approximating a manifold by locally projecting down tangent spaces was developed. Very little of the machinery is needed. As stated in Theorem 3.1 the tangent space $T_p M'$ to $M'$ at $p = [x, u] \in M'$ is given by $\text{null}(\nabla g^*(p))$. Let $U'$ be an orthonormal basis for $T_p M'$. Then the vector $q_0 = p + U'w$ lies in $T_p M'$ when the latter is viewed as an affine subspace of $\mathbb{R}^{2m+1}$. Set $N' = [\nabla g^*(p)]^+$ where $A^+$ is the Moore-Penrose pseudoinverse of the matrix $A$. The tangent vector $q_0$ is projected down onto $M'$ by
\[ q_{n+1} = q_n - N' g^*(q_n), \quad n = 0, 1, \ldots, \] with $q_0 = p + U'w$ (3b)
for some $w \in \mathbb{R}^m$. Computationally this is the most attractive of the procedures presented and is the one we will use for the remainder. Since this is a numerical implementation of the implicit function theorem there will be a radius around the origin in $T_p M'$ where it will be guaranteed to converge to a point on $M'$. This is restated as a restriction on the length of the $w$ in (3b).

7 The Optimization Procedure

All of the pieces are in place to state the optimization procedure. Let the optimization problem be stated as
\[ \min_{z \in \mathbb{R}^{m+k}} f(z) \text{ subject to } \tilde{g}(z) \leq 0 \] with $\tilde{g} : \mathbb{R}^{m+k} \to \mathbb{R}^k$ and $\tilde{g}_i \in Q[z]$. Triangularize $\tilde{g}(z)$ into $g(z)$ which has the structure presented in [2]. Take $g^* : \mathbb{R}^{2m+1} \to \mathbb{R}^{m+1}$ as defining the manifold $M'$.

We will assume we have a black-box implementation $B(U', w)$ of the mapping defined by $\tilde{g}(z)$. $B(U', w)$ will return FALSE if the algorithm doesn’t converge to a point on $M'$ close to the base point $p \in M'$. That is, $B(U', w)$ is also an oracle for when the implicit function theorem no longer holds around
Tangents Let \( U_j = 0 \) and set the current base point \( f = \rho \). The forcing function be \( \Phi = f \). See Figure 1 for the solution set of \( g \) for Procedure 1. Let the equality constraints be given by

Here we look at a simple example that demonstrates how to find the pieces

8 An Example

Here we look at a simple example that demonstrates how to find the pieces for Procedure 1. Let the equality constraints be given by

\[
g(y, x, u) = \begin{bmatrix} u^2 + x^3 + y^5 \\ u^4 + x^2 - 1 \end{bmatrix} = 0.
\]

See Figure 1 for the solution set of \( g(y, x, u) \). This triangularized system of
polynomials gives the pair
\[ g^*(x, u) = u^4 + x^2 - 1 \]
\[ g^0(y; x, u) = u^2 + x^3 + y^5. \]

Using \( g^0(y; x, u) \) we can find \( y \) as a function of \( x \) and \( u \):
\[ y(x, u) = -\sqrt[5]{u^2 + x^3}. \]

This is the implicit function we need to map from \( M' \) back to \( M \). From this we have \( \Phi = [y(x, u) \ x \ u] \). We also need the gradient of \( g^*(x, u) \) to find the tangent space of \( M' \):
\[ \nabla g^*(x, u) = \begin{bmatrix} 2x \\ 4u^3 \end{bmatrix}. \]

Looking at Figure 1 we see that at least two different tangent spaces are required to implement the implicit function mapping \( T_p M' \to M' \). For \( \mathcal{B}(U', w) \) we could have it return FALSE whenever, say, \( \|q_0 - q_0\| > 1/2 \), with the \( q_i \) as in (3). This would require more than two different tangent spaces to cover \( M' \) but it’s likely an acceptable criterion to function as an oracle.

**9 Conclusions**

We have not implemented the procedure in Section 7 numerically. There are multiple components to the method each of which is a significant undertaking in itself to be done correctly and efficiently. However this was not our main purpose. Rather we wished to draw upon classic and recent results that work together in ways that are perhaps novel for nonlinear optimization problems.
