WELL-POSEDNESS, DISCRETIZATION AND PRECONDITIONERS FOR A
CLASS OF MODELS FOR MIXED-DIMENSIONAL PROBLEMS WITH HIGH
DIMENSIONAL GAP

ERLEND HODNELAND†, XIAOZHE HU‡, AND JAN MARTIN NORDBOTTEN §

Abstract. In this work, we illustrate the underlying mathematical structure of mixed-dimensional models arising from the composition of graphs and continuous domains. Such models are becoming popular in applications, in particular, to model the human vasculature. We first discuss the model equations in the strong form which describes the conservation of mass and Darcy’s law in the continuum and network as well as the coupling between them. By introducing proper scaling, we propose a weak form that avoids degeneracy. Well-posedness of the weak form is shown through standard Babuška-Brezzi theory. We also develop the mixed formulation finite-element method and prove its well-posedness. A mass-lumping technique is introduced to derive the two-point flux approximation type discretization as well, due to its importance in applications. Based on the Babuška-Brezzi theory, error estimates can be obtained for both the finite-element scheme and the TPFA scheme. We also discuss efficient linear solvers for discrete problems. Finally, we present some numerical examples to verify the theoretical results and demonstrate the robustness of our proposed discretization schemes.

Key words. Mixed-dimensional problems, mixed-formulation finite-element method

1. Introduction. Coupled fluid flow in networks and porous domains arise in various applications, including blood flow in the human body as well as wells in geological applications. Such models are referred to as mixed-dimensional when the network flow is simplified to a family of 1D domains along with the network edges. Moreover, when the coupling between the network and the domain exceeds two topological dimensions, the model is referred to as having a high dimensional gap [26, 21]. A high dimensional gap thus arises when the flow in the network is connected to a domain of dimension $d \geq 2$ through its leaf nodes, or when the flow in the network is connected to a domain of dimension $d \geq 3$ through its edges.

In this paper, we consider the problem composed of flow in one or more trees, coupled with a (porous) domain. This setting is motivated by blood flow in the brain, wherein the networks are the arterial and venous trees, and the domain is the sub-resolution capillary bed. Recognizing that the leaf nodes in the tree (referred to as “terminals” hereafter) are in applications an artifact of limited imaging resolution, we consider in our equations a mesoscale model wherein fluid is distributed into the porous domain in a support region near the terminals. Such models have recently been introduced in [14] and also considered in [18], and are attractive also from a mathematical perspective, as they avoid the singularities which otherwise characterize the coupled equations. In this work, we will not adopt the precise models used in [14, 18] directly, as they consider an explicitly given

1 Some authors refer to this problem as multiscale (see e.g. [11, 20]), however, we prefer the nomenclature mixed-dimensional to avoid confusion with equidimensional multiscale methods such as are encountered in (numerical) homogenization problems.

structure of fluid distribution between the network and the porous domain. In contrast, we will use a more canonical formulation, where the flow resistance is given, and the fluid distribution from the terminal is calculated.

Previous mathematical analysis of models with high dimensional gap has to a large extent been focused on how to handle the singularities arising when the coupling is "point-wise" between the network and the domain (see e.g. [11, 19, 12]). In contrast, the model discussed herein has to our knowledge not been subjected to mathematical analysis before. In the absence of singularities, we exploit in this paper the framework recently developed for problems with small dimensional gap [7], and define mixed-dimensional variables and operators for the coupled problem. Together with appropriately defined integration and inner products, we then observe that we have available tools such as a mixed-dimensional Stokes' theorem, integration by parts, and Hilbert spaces. This forms the building blocks for our well-posedness results and numerical analysis.

The main results of the paper are thus as follows:
- A general, non-singular model for a class of problems with a large dimensional gap.
- Well-posedness theory for both the continuous and finite-dimensional problem.
- Convergence results for mixed finite-element approximation and a finite volume variant.
- Efficient linear solvers for different discretizations.
- Numerical validation and application to a high-resolution data-set of a real human brain.

We structure the paper as follows. In Section 2 we present the model equations in both strong and weak forms and show well-posedness. In Section 3 and 4 we state and analyze the finite-element and finite volume approximations, respectively. Efficient solvers for the coupled problem are proposed in Section 5. The theoretical results are validated in Section 6. Finally, we give some conclusions in Section 7.

2. Model Equations. In this section, we discuss the basic model equation for modeling the coupled network-Darcy flow in brain. We will first discuss its strong form and then derive the weak form by introducing proper spaces.

2.1. Strong Form. We are concerned with a domain $\Omega \subset \mathbb{R}^n$ (which models the capillaries). In addition, we are concerned with a finite collection of rooted trees $T$ with node (vertex) set $N_T$ and edge set $E_T$ (which model resolved arteries and veins). Those trees are disjoint and, therefore, form a forest $\mathcal{F}$ with node set $N = \bigcup_{T \in \mathcal{F}} N_T$ and edge set $E = \bigcup_{T \in \mathcal{F}} E_T$. The node set $N$ can be subdivided into three disjoint subsets, the first and last of which are assumed to be non-empty: root nodes $N_R$, interior nodes $N_I$, and terminal nodes $N_T$. Note that $N = N_R \cup N_I \cup N_T$ and we use $N_{T,R} = N_T \cap N_R$, $N_{T,I} = N_T \cap N_I$, and $N_{T,T} = N_T \cap N_T$ to denote the root nodes, interior nodes, and the terminal nodes of a given tree $T$, respectively. Naturally, we also have $N_T = N_{T,R} \cup N_{T,I} \cup N_{T,T}$. We further divided the root nodes $N_R$ into two disjoint sets $N_D$, which consists of the Dirichlet root nodes, and $N_N$, which consists of the Neumann root nodes. The Dirichlet root nodes will be treat explicitly as Dirichlet boundary conditions and the Neumann root nodes will be implicitly handled through the right-hand side of the conservation laws on the graph. Following the same convention, $N_{T,D}$ and $N_{T,N}$ denotes the Dirichlet or Neumann root nodes of a given tree $T$, respectively. Note that each tree can only have one root. Therefore, we can subdivide the forest into two disjoint sub-forests, i.e., Dirichlet rooted forest $\mathcal{F}_D$, which contains all the Dirichlet rooted trees $T_D$, and Neumann rooted forest $\mathcal{F}_N$, which contains all the Neumann rooted trees $T_N$. Naturally, $N_{\mathcal{F}_D} = \bigcup_{T \in \mathcal{F}_D} N_T$ and $N_{\mathcal{F}_N} = \bigcup_{T \in \mathcal{F}_N} N_T$. Furthermore, we define, $N_{T,D,R} = N_{T,D} \cap N_R$, $N_{T,D,I} = N_{T,D} \cap N_I$, $N_{T,D,T} = N_{T,D} \cap N_T$, $N_{T,N,R} = N_{T,N} \cap N_R$, $N_{T,N,I} = N_{T,N} \cap N_I$, and $N_{T,N,T} = N_{T,N} \cap N_T$. We denote the set of the neighbors of the node $i$
as $N_i$ and the set of all the edges meeting at $i \in \mathcal{N}$ as $\mathcal{E}_i$. Note that, $|N_i| = 1$ and $|\mathcal{E}_i| = 1$, if $i \in \mathcal{N}_R \cup \mathcal{N}_T$. These concepts are illustrated for $n = 2$ in Figure 1.

As primary variables we choose the domain pressure potential $p^D(x) : \Omega \mapsto \mathbb{R}$ and the node pressure potentials $p^N : \mathcal{N} \mapsto \mathbb{R}$. Furthermore, we consider the fluid mass fluxes denoted in the domain as $q^D(x) : \Omega \mapsto \mathbb{R}^n$, fluid mass flow from node $i$ to $j$ denoted $q^N_{i,j} : \mathcal{N} \times \mathcal{N} \mapsto \mathbb{R}$ and fluid mass flow transferring from terminal node $i$ to point $x$ denoted $q^T_i(x) : \Omega \mapsto \mathbb{R}$. This last variable models the flow in unresolved arteries and veins, and is a novel component our this work.

First, we consider the model equations for mass conservation and they are given as follows based on the above definitions and notation.

\begin{align}
(2.1) \quad \text{Conservation of mass in brain tissue} \quad & \nabla \cdot q^D - \sum_{i \in \mathcal{N}_T} q^T_i = r^D, \quad \text{in } \Omega \\
(2.2) \quad \text{Conservation of mass at interior nodes} \quad & - \sum_{j \in N_i} q^N_{j,i} = r^N_i, \quad \text{for all } i \in \mathcal{N}_I \cup \mathcal{N}_N \\
(2.3) \quad \text{Conservation of mass at terminal nodes} \quad & \int_{\Omega} q^T_i(x) \, dx - q^N_{i,N_i,i} = r^N_i, \quad \text{for all } i \in \mathcal{N}_T
\end{align}

Here, the signs in (2.1)-(2.3) are chosen such that the right-hand-side terms represent sources added to the system. Moreover, although both $q^N_{i,j}$ and $q^N_{j,i}$ are used in (2.2) for notational convenience, they should be understood as one unknown with a sign difference.
Next we verify the global conservation of mass based on (2.1)-(2.3) as follows,

\[(\text{Stokes’ Theorem})\]

\[
\int_{\partial \Omega} \mathbf{q} \cdot \mathbf{n} \, d\mathbf{x} = \int_{\Omega} \nabla \cdot \mathbf{q} \, d\mathbf{x}
\]

(By (2.1))

\[
= \sum_{i \in \mathcal{N}_T} \int_{\Omega} q^T_i(x) \, d\mathbf{x} + \int_{\Omega} r^D \, d\mathbf{x}
\]

(By (2.3))

\[
= \sum_{i \in \mathcal{N}_T} q^N_i, + \sum_{i \in \mathcal{N}_T} r^N_i + \int_{\Omega} r^D \, d\mathbf{x}
\]

(By (2.2))

\[
= \sum_{i \in \mathcal{N}_D} q^N_i, + \sum_{i \in \mathcal{N}_T \cup \mathcal{N}_N \cup \mathcal{N}_I \cup \mathcal{N}_T} r^N_i + \int_{\Omega} r^D \, d\mathbf{x}.
\]

Where the last step is also known as the Graph-Stokes’ Theorem, which is the counterpart of the
Stokes’ Theorem on graphs.

In order to present the constitutive laws properly, we need to introduce some material parameters, all of which are assumed to be non-negative (precise bounds are given later). For each edge \(e(i, j) \in \mathcal{E}\), we assign a conductivity \(k^N_{e(i, j)}\), which can be considered as the edge weights in certain sense. In the domain, for each \(x \in \Omega\) we assign a permeability tensor \(k^D(x) : \Omega \mapsto \mathbb{R}^{n \times n}\). For each terminal node \(i \in \mathcal{N}_T\), we assign connectivity function \(k^T_i(x) : \Omega \mapsto \mathbb{R}\). Now based on the assumption that the potential flow is linear, we have the following constitutive laws.

(2.4) (Potential flow in brain (Darcy)) \[q^D = -k^D(x)\nabla p^D, \quad \text{in} \ \Omega,\]

(2.5) (Potential flow in network (Poiseuille)) \[q^N_{i,j} = -k^N_{e(i,j)} (p^N_j - p^N_i), \quad \text{for} \ e(i, j) \in \mathcal{E},\]

(2.6) (Potential flow from network to brain) \[q^T_i(x) = -k^T_i(x) (p^D - p^N_i), \quad \text{for} \ i \in \mathcal{N}_T.\]

The coefficient functions \(k^T_i(x), i \in \mathcal{N}_T\), represent redistribution in a small region around the terminal node \(i\), thus, can be assumed to have compact support in some domain \(B_i \subseteq \Omega\).

Remark 2.1. In practice the characteristic length scale of \(B_i\) is comparable to the distance to the nearest neighbor, i.e.

\[(2.7) \quad \text{diam}(B_i) = \mathcal{O} \left( \min_{j \in \mathcal{N}_T} |x_i - x_j| \right).\]

Moreover, the grid is frequently given by the voxel resolution of the image and the terminals are due to a finite resolution effect, and thus

\[(2.8) \quad \min_{j \in \mathcal{N}_T} |x_i - x_j| = \mathcal{O}(h),\]

where \(h\) is the mesh size. The constants hidden in the \(\mathcal{O}\) notation in (2.7) and (2.8) are usually between 2 to 10 in practical applications that we are interested in. Consequentially, \(q^T_i(x)\) also is compactly supported in \(B_i\). While these considerations could be applied to further refine some of the constants in the proofs below, we will not exploit these details in this paper.

In addition to the conservation laws and constitutive laws, we also need boundary conditions to close the system. For the sake of simplicity, we only consider the case of homogeneous Neumann data on \(\partial \Omega\) and the Dirichlet root nodes \(\mathcal{N}_D\), i.e.,

\[(2.9) \quad q^D \cdot n = 0 \quad \text{on} \ \partial \Omega \quad \text{and} \quad p^N_i = 0, \quad i \in \mathcal{N}_D.\]
conservation laws (2.1)-(2.3) can be summarized as
\[ k_i = q_i \]

where
\[ v_i = q_i \]

and its transpose serves as a discrete divergence.

We want to point out that the signed incidence matrix represents a discrete gradient on the graph and its transpose serves as a discrete divergence.

2.2. Mixed-dimensional formulation and scaling. The model equations given above contain essentially three expressions of fluxes \([q^D, q^T, q^N]\), and two expressions of potentials \([p^D, p^N]\). It will simplify the following exposition and analysis considerably to treat these as mixed-dimensional operators.

Therefore, let the mixed-dimensional flux be denoted \(q\), and defined as the triplet of fluxes \(q := [q^D, q^T, q^N]\). Equivalently, the mixed-dimensional pressure is denoted and defined as \(p := [p^D, p^N]\).

Now, we define the mixed-dimensional divergence operator \(\mathcal{D}\) as follows,
\[
\mathcal{D} \cdot q = \mathcal{D} \cdot [q^D, q^T, q^N] := [u^D, u^N],
\]

where
\[
u^D := \nabla \cdot q^D - \sum_{i \in \mathcal{N}_T} q^T_i \quad \text{and} \quad u^N_i = \begin{cases} - \sum_{j \in \mathcal{N}_i} q^N_{j,i}, & i \in \mathcal{N}_I \cup \mathcal{N}_N, \\ \int_{B_i} q^T_i(x) \, dx - q^N_{N_i,i}, & i \in \mathcal{N}_T. \end{cases}
\]

Similarly, we define the mixed-dimensional gradient \(\mathcal{D}\) as
\[
\mathcal{D}p = \mathcal{D}[p^D, p^N] := [v^D, v^T, v^N],
\]

where
\[
u^D := \nabla p^D \quad \text{and} \quad v^T_i(x) := p^D(x) - p^N_i, \quad i \in \mathcal{N}_T, \quad \text{and} \quad v^N = \mathcal{G}p^N.
\]

In addition, we introduce the function \(\mathcal{R}\) which contains all the material functions \(k^D, k^T(x), k^N_{e(i,j)}, e(i,j) \in \mathcal{E}\), in (2.4) to (2.6), such that
\[
\mathcal{R}^{-1}[q^D, q^T, q^N] := [(k^D)^{-1}q^D, (k^T)^{-1}q^T, (k^N)^{-1}q^N],
\]

where \(k^N = \text{diag}(k^N_{e(i,j)})\). It is now straightforward to verify that with these definitions, the conservation laws (2.1)-(2.3) can be summarized as
\[
\mathcal{D} \cdot q = r,
\]
where \( r \equiv [r^D, r^N] \). Furthermore, the constitutive laws (2.4) to (2.6) can be summarized as

\begin{equation}
(2.16) \quad q = -K D p.
\end{equation}

While the physical model formulation is satisfactory for non-degenerate \( k^T_i(x), i \in \mathcal{N}_T \), it will be beneficial to rescale the coupling flux to avoid considering a degenerate mass matrix when \( k^T_i(x) \rightarrow 0 \) for some points or region in \( B_i \). To that aim, we introduce the square-root of the transfer coefficient \( k^S_i(x) = \sqrt{k^T_i(x)}, i \in \mathcal{N}_T \), and the scaled transfer flux \( q^S_i(x) : \Omega \rightarrow \mathbb{R} \), \( i \in \mathcal{N}_T \), is defined as

\begin{equation}
q^S_i(x) = (k^S_i(x))^{-1} q^T_i(x).
\end{equation}

Thus, we replace (2.1) (2.3), and (2.6) with

\begin{align}
(2.17) \quad \text{(Conservation of mass in brain tissue)} & \quad \nabla \cdot q^D - \sum_{i \in \mathcal{N}_T} k^S_i q^S_i = r^D, \quad \text{in } \Omega, \\
(2.18) \quad \text{(Conservation of mass at terminal nodes)} & \quad \int_{B_i} k^S_i q^S_i(x) dx - q^N_{N,i} = r^N_i \quad \text{for all } i \in \mathcal{N}_T, \\
(2.19) \quad \text{(Potential flow from network to brain)} & \quad q^S_i(x) = -k^S_i(x) (p^D - p^N_i), \quad \text{for } i \in \mathcal{N}_T,
\end{align}

respectively. We note that a similar scaling has been applied previously to handle degeneracies occurring in mantle dynamics [3] and flows in fractured porous media [8].

Equivalently, We denote the scaled mixed-dimensional flux as \( q^S \equiv [q^D, q^S, q^N] \), and the scaling \( S \) such that

\begin{equation}
S^{-1}[q^D, q^T, q^N] := [q^D, (k^S)^{-1} q^T, q^N].
\end{equation}

Thus, \( q^S = S q \), and we can introduce the rescaled divergence and gradients as \( \mathcal{D}^S := \mathcal{D} \cdot S \) and \( \mathcal{D}^S := \mathcal{S} \mathcal{D} \), respectively. The rescaled conservation equations are then summarized as

\begin{equation}
(2.20) \quad \mathcal{D}^S \cdot q^S = r.
\end{equation}

The rescaled conservation equations are summarized as

\begin{equation}
(2.21) \quad q^S = -\mathcal{R}^S \mathcal{D}^S p,
\end{equation}

where \( \mathcal{R}^S = S^{-1} \mathcal{R} S^{-1} \).

In this setting, we allow for degeneracy of the coupling term in the sense that we allow \( k^S_i(x) \rightarrow 0 \). However, we require that \( k^S_i(x) \) is bounded from above, i.e., \( k^S_i(x) \leq C_k^S \) for \( i \in \mathcal{N}_T \) and \( x \in \Omega \). Furthermore, for all \( i \), we require it to hold that

\begin{equation}
\int_{B_i} k^S_i(x) dx = c_k^S \geq C_k^S > 0,
\end{equation}

where \( c_k^S \) is a generic constant.

2.3. Weak Form. In this subsection, we derive the weak formulation of the system. The development will be equally valid for both the original model, equations (2.15) and (2.16), as well as the re-scaled model, equations (2.20) and (2.21). Thus we will omit the superscript \( S \) on the mixed-dimensional operators and variables to reduce notational overload. Nevertheless, in order to allow for degeneracies, we will always have the rescaled equations in mind, and thus when we need to specifically refer to \( q^S \), and consider the coefficient \( k^S \) to appear in the differential operator as opposed to the material law.
We first introduce proper function spaces. We begin by defining a mixed-dimensional square-integrable space for pressure as follows,

\[ \mathcal{L}^2 := L^2(\Omega) \times l^2(\mathcal{N} \setminus \mathcal{N}_D), \]

where \( L^2(\Omega) \) is the standard \( L^2 \) space defined on domain \( \Omega \) and \( l^2(\mathcal{N} \setminus \mathcal{N}_D) \) is the standard \( l^2 \) space defined on the node set \( \mathcal{N} \setminus \mathcal{N}_D \). For flux, we consider a space with bounded mixed-dimensional divergence as follows,

\[ \mathfrak{H}(\text{div}) := H(\text{div}, \Omega) \times \prod_{i \in \mathcal{N}_T} L^2(B_i) \times l^2(\mathcal{E}) \]

where \( H(\text{div}, \Omega) \) is the space defined on \( \Omega \) such that the functions and their divergence are both square-integrable. In addition, \( L^2(B_i) \) are standard \( L^2 \) space defined on \( B_i, i \in \mathcal{N}_T \), and \( l^2(\mathcal{E}) \) is the standard \( l^2 \) space defined on the edge set \( \mathcal{E} \).

We associate the mixed-dimensional space \( \mathcal{L}^2 \) with the following inner product,

\[ (p, w) = ([p^D, p^N], [w^D, w^N]) := \int_\Omega p^D w^D \, dx + \sum_{i \in \mathcal{N} \setminus \mathcal{N}_D} p_i^N w_i^N, \quad \forall p, w \in \mathcal{L}^2. \]

Similarly, we introduce the following inner product on \( \mathfrak{H}(\text{div}) \),

\[ (q, v) = ([q^D, q^S, q^N], [v^D, v^S, v^N]) := \int_\Omega q^D \cdot v^D \, dx + \sum_{i \in \mathcal{N}_T} \int_{B_i} q_i^S v_i^S \, dx + \sum_{e(i,j) \in \mathcal{E}} q_{i,j}^N v_{i,j}^N. \]

It is important to note that the inner products are defined such that integration-by-parts holds in for the mixed-dimensional operators (both original and re-scaled cases).

**Lemma 2.2 (Integration by parts).** For any \( q \in \mathfrak{H}(\text{div}) \) and \( p \in \mathcal{L}^2 \), we have

\[ (\mathcal{D}p, q) + (p, \mathcal{D} \cdot q) = \int_{\partial \Omega} p^D q^D \cdot n \, dx + \sum_{i \in \mathcal{N}_D} p_i^N q_{N,i}^N. \]

**Proof.** By a direct calculation (using the re-scaled operators and variables, the derivation for the original case is the same), we have that

\[ (p, \mathcal{D} \cdot q) = \int_\Omega p^D \left( \nabla \cdot q^D - \sum_{i \in \mathcal{N}_T} k_i^S q_i^S \right) \, dx - \sum_{i \in \mathcal{N}_T} \sum_{j \in \mathcal{N}_i} p_i^N q_{j,i}^N \]

\[ + \sum_{i \in \mathcal{N}_T} p_i^N \left( \int_{B_i} k_i^S q_i^S \, dx - q_{N,i}^N \right) \]

\[ = -\int_\Omega \nabla p^D \cdot q^D \, dx + \int_{\partial \Omega} p^D q^D \cdot n \, dx - \sum_{e(i,j) \in \mathcal{E}} (p_i^N - p_j^N) q_{i,j}^N \]

\[ + \sum_{i \in \mathcal{N}_D} p_i^N q_{N,i}^N - \sum_{i \in \mathcal{N}_T} \int_{B_i} k_i^S (p^D - p_i^N) q_i^S \, dx \]

\[ = \int_{\partial \Omega} p^D q^D \cdot n \, dx + \sum_{i \in \mathcal{N}_D} p_i^N q_{N,i}^N - (\mathcal{D}p, q), \]
which completes the proof.

To derive the weak formulation, we need to incorporate the boundary conditions. Recall that we consider \( \mathbf{q}^D \cdot \mathbf{n} = 0 \) on \( \partial \Omega \), therefore, we define the following functions space with boundary conditions,

\[
\mathcal{H}_0(\text{div}) := H_0(\text{div}, \Omega) \times \prod_{i \in \mathcal{N}_T} L^2(B_i) \times L^2(\mathcal{E}) \subset \mathcal{H}(\text{div}),
\]

where \( H_0(\text{div}, \Omega) := \{ \mathbf{q}^D \in H(\text{div}, \Omega) \mid \mathbf{q}^D \cdot \mathbf{n} = 0, \text{ on } \partial \Omega \} \). In addition, with the material function \( \mathcal{K} \), we introduce a weighted inner product on \( \mathcal{H}(\text{div}) \) as follows,

\[
(\mathbf{q}, \mathbf{v})_{\mathcal{R}^{-1}} := (\mathcal{K}^{-1} \mathbf{q}, \mathbf{v}).
\]

Using the above function spaces and notation, together with the mixed-dimensional integration by parts formula (2.22) and the homogeneous Dirichlet boundary conditions (2.9) on \( \mathcal{N}_D \), i.e., \( p_i^N = 0, \text{ } i \in \mathcal{N}_D \), we have the following weak form for the conservation laws (2.17), (2.2), (2.18) and constitutive laws (2.4), (2.5), (2.19): Find \( \mathbf{q} \in \mathcal{H}_0(\text{div}) \) and \( p \in \mathcal{L}^2 \), such that

\[
(2.23) \quad (\mathbf{q}, \mathbf{v})_{\mathcal{R}^{-1}} - (p, \mathcal{D} \cdot \mathbf{v}) = 0, \quad \forall \mathbf{v} \in \mathcal{H}_0(\text{div}),
\]

\[
(2.24) \quad - (\mathcal{D} \cdot \mathbf{q}, \mathbf{w}) = - (r, \mathbf{w}), \quad \forall \mathbf{w} \in \mathcal{L}^2.
\]

Note that due to the integration by parts formula, if non-homogeneous boundary data is considered, this would appear as extra right-hand side terms in equation (2.23).

2.4. Well-posedness. In this subsection, we focus on the well-posedness of the weak formulation (2.23)-(2.24). We first introduce the following norm on \( \mathcal{L}^2 \),

\[
(2.25) \quad \|p\|^2_{\mathcal{L}^2} := (p, p).
\]

And the following norm on \( \mathcal{H}(\text{div}) \),

\[
(2.26) \quad \|\mathbf{q}\|^2_{\mathcal{H}(\text{div})} := \|\mathbf{q}\|^2_{\mathcal{R}^{-1}} + \|\mathcal{D} \cdot \mathbf{q}\|^2_{\mathcal{L}^2},
\]

where

\[
(2.27) \quad \|\mathbf{q}\|^2_{\mathcal{R}^{-1}} := (\mathbf{q}, \mathbf{q})_{\mathcal{R}^{-1}}.
\]

Next lemma shows that the bilinear forms in the weak formulation (2.23)-(2.24) are continuous.

**Lemma 2.3 (Continuity of (2.23)-(2.24)).** For any \( \mathbf{q}, \mathbf{v} \in \mathcal{H}(\text{div}) \) and \( \mathbf{w} \in \mathcal{L}^2 \), we have

\[
(\mathbf{q}, \mathbf{v})_{\mathcal{R}^{-1}} \leq \|\mathbf{q}\|_{\mathcal{H}(\text{div})} \|\mathbf{v}\|_{\mathcal{H}(\text{div})},
\]

\[
(\mathcal{D} \cdot \mathbf{q}, \mathbf{w}) \leq \|\mathbf{q}\|_{\mathcal{H}(\text{div})} \|\mathbf{w}\|_{\mathcal{L}^2}.
\]

**Proof.** The continuity of both bilinear forms follow directly from the Cauchy-Schwarz inequality and the definition of the norms (2.26) and (2.25).

Now we show the ellipticity of the inner product \( (\cdot, \cdot)_{\mathcal{R}^{-1}} \) on the kernel of the mixed-dimensional divergence operator \( \mathcal{D} \) in the following lemma.
Lemma 2.4 (Ellipticity of (2.23)-(2.24)). If \( q \in \mathcal{H}(\text{div}) \) satisfies
\[
(2.28) \quad (\mathbf{D} \cdot q, w) = 0, \quad \forall w \in \mathcal{L}^2,
\]
then
\[
(2.29) \quad (q, q)_{K^{-1}} = ||q||^2_{\mathcal{H}(\text{div})}.
\]

Proof. Since \( \mathbf{D} \cdot q \in \mathcal{L}^2 \), from (2.28), we have
\[
||\mathbf{D} \cdot q||_{\mathcal{L}^2} = 0.
\]
Therefore, (2.29) follows directly from the above identity and the definition of the norm (2.26). □

Next, we discuss the inf-sup condition of the bilinear form \((r, \mathbf{D} \cdot q)\) in the following lemma.

Lemma 2.5 (Inf-sup condition of (2.23)-(2.24)). There exists a constant \( \beta > 0 \) such that, for any given function \( r \in \mathcal{L}^2 \),
\[
(2.30) \quad \sup_{q \in \mathcal{H}_0(\text{div})} \frac{(r, \mathbf{D} \cdot q)}{||q||_{\mathcal{H}(\text{div})}} \geq \beta ||r||_{\mathcal{L}^2}.
\]

Here, the inf-sup constant \( \beta \) depends on \(|B_i| = \text{measure}(B_i)\), the maximal number of overlaps between \( B_i \), structure of the trees \( T \in \mathcal{F} \), the domain \( \Omega \), and the constants \( c_{k,s} \) and \( C_{k,s} \).

Proof. Assume \( r = [r^D, r^N] \in \mathcal{L}^2 \) given, we first aim to construct \( q = [q^D, q^S, q^N] \in \mathcal{H}_0(\text{div}) \) such that \( \mathbf{D} \cdot [q^D, q^S, q^N] = [r^D, r^N] \).

First step is to construct \( q^N \) based on the forest \( \mathcal{F} \). Based on the signed incidence matrix \( G \) (2.10), we omit those columns that correspond to the Dirichlet root nodes to obtain the signed incidence matrix with boundary conditions \( G_{\mathcal{F}} \). Then, we consider the following mixed-formulation graph Laplacian problem: Find \( q_{\mathcal{F}} \in \mathbb{R}^{|E\mathcal{F}|} \) and \( \psi_{\mathcal{F}} \in \mathbb{R}^{|N\mathcal{F}| - |N_{D\mathcal{F}}|} \)
\[
(2.31) \quad \mathcal{R}^{-1} q_{\mathcal{F}} - G_{\mathcal{F}} \psi_{\mathcal{F}} = 0,
\]
\[
(2.32) \quad G_{\mathcal{F}}^T q_{\mathcal{F}} = r_{\mathcal{F}}.
\]
Here, for trees \( T \in \mathcal{F}_N \), we set \( (r_{\mathcal{F}})_i = r^N_i, \ i \in N_{T,N} \cup N_{T,I} \), and for \( i \in N_{T,T} \), we choose \( (r_{\mathcal{F}})_i \) such that \( \sum_{i \in N_T} (r_{\mathcal{F}})_i = 0 \). The choice is not unique, and here we choose
\[
(2.33) \quad (r_{\mathcal{F}})_i = r^N_i - \sum_{i \in N_T} r^N_i \frac{r^N_i}{|N_{T,T}|}, \quad i \in N_{T,T}, \quad T \in \mathcal{F}_N.
\]

For trees \( T \in \mathcal{F}_D \), we set \( (r_{\mathcal{F}})_i = r^N_i, \ i \in N_{T,T} \cup N_{T,I} \), and, for \( i \in N_{T,T} \), we set
\[
(2.34) \quad (r_{\mathcal{F}})_i = r^N_i + \frac{1}{|N_{\mathcal{F}_D,T}|} \int_{\Omega} r^D \, dx + \frac{1}{|N_{\mathcal{F}_D,T}|} \sum_{i \in N_{\mathcal{F}_D}} r^N_i, \quad i \in N_{\mathcal{F}_D,T}.
\]

The reason of such a choice will be made clear later in the proof when we construct \( q^D \). Note that, since the degree of node \( i \in N_{T,T} \) is one, once \( (r_{\mathcal{F}})_i \) is fixed, we naturally have \( (q_{\mathcal{F}})_e(N_{i,i}) = -(r_{\mathcal{F}})_i \).

With this choice of \( r_{\mathcal{F}} \), the mixed-formulation graph Laplacian problem (2.31)-(2.32) is well-posed.
in the sense that \( \psi_F \) is unique (up to a constant on the trees \( T \in \mathcal{F}_N \)) and \( q_F \) is uniquely defined. Once \( q_F \) is obtained, we define \( q^N \) by \( q^N_{i,j} = (q_F)_{e(i,j)}, e(i,j) \in \mathcal{E} \).

From the mixed-formulation (2.31)-(2.32), we have the following estimates,

\[
\|G^T_q F\|^2 = \|r_F\|^2 \quad \text{and} \quad (\mathcal{A}^{-1} q_F, q_F) \leq (\lambda_{\min}^F)^{-1} \|r_F\|^2, \tag{2.34}
\]

where \( \lambda_{\min}^F \) is the smallest non-zero eigenvalue of the weighted graph Laplacian of the forest \( F \), i.e., \( \mathcal{L}_F = G^T_F \mathcal{A} G_F \). We comment that \( \lambda_{\min}^F \) is bounded below by the so-called Cheeger constant of the graph, so depends on the structure of the trees \( T \) in the forest \( F \). Note that

\[
\|r_F\|^2 = \sum_{i \in \mathcal{N}_T} (r^N_i)^2 + \sum_{i \in \mathcal{N}_{D,T}} ((r_F)_i)^2 + \sum_{i \in \mathcal{N}_{D,T}} (|r^N_F|)^2
\]

and, due the choice (2.33), the last term on the right-hand-side can be bounded by

\[
\sum_{i \in \mathcal{N}_{D,T}} (|r^N_F|)^2 \leq C_N \sum_{i \in \mathcal{N}_{D,T}} (r^N_i)^2 \tag{2.35}
\]

with \( C_N = 2 \left( \max_{T \in \mathcal{F}_N} \frac{|\mathcal{N}_T|}{|\mathcal{N}_{D,T}|} + 1 \right) \). Similarly, by Cauchy-Schwarz inequality, the second term on the right-hand-side can be bounded as follows,

\[
\sum_{i \in \mathcal{N}_{D,T}} (|r^N_F|)^2 \leq C_D \left[ \sum_{i \in \mathcal{N}_{D,T}} (r^N_i)^2 + \sum_{i \in \mathcal{N}_{N}} (r^N_i)^2 + \int_\Omega (r_D)^2 \, dx \right], \tag{2.36}
\]

where \( C_D = 3 \max \left\{ 1, \frac{|\mathcal{G}|}{|\mathcal{N}_{D,T}|}, \frac{|\mathcal{N}_N|}{|\mathcal{N}_{D,T}|} \right\} \).

Therefore, combining the estimates (2.34), (2.35), (2.36), and the definitions of \( G_F \) and \( q^N \), the following estimate holds,

\[
\sum_{e(i,j) \in \mathcal{E}} (k^N_{e(i,j)})^{-1} |q^N_{i,j}|^2 \leq C_q^N \left[ \sum_{i \in \mathcal{N}_T} (r^N_i)^2 + \sum_{i \in \mathcal{N}_{T}} (r^N_i)^2 + \int_\Omega (r_D)^2 \, dx \right], \tag{2.37}
\]

where \( C_q^N = (\lambda_{\min}^F)^{-1} (C_N + C_D + 1) \).

Next we construct \( q^S \) from \( q^N \) and \( r^N \) so that (2.18) is satisfied exactly, i.e., we define, for each terminal nodes \( i \in \mathcal{N}_T \),

\[
q^S_i(x) = \frac{q^N_{i,N - i} + r^N_i}{c_{k_i}}, \quad x \in B_i. \tag{2.38}
\]

From the construction, we have

\[
\sum_{i \in \mathcal{N}_T} \int_{B_i} |q^S_i(x)|^2 \, dx \leq \frac{2 |B_i|}{c_{k^S}} \left[ \sum_{i \in \mathcal{N}_T} |r^N_i|^2 + \sum_{i \in \mathcal{N}_{D,T}} |q^N_{i,j}|^2 \right] \leq C_{q^S} \left[ \sum_{i \in \mathcal{N}_T} |r^N_i|^2 + \sum_{i \in \mathcal{N}_{D,T}} |r^N_i|^2 + \int_\Omega (r_D)^2 \, dx \right], \tag{2.39}
\]
where $C_{q^D} = \frac{2B_1}{\epsilon^2} (C_N + C_D)$. Here we use the fact that $q_{N,i}^N = -r_F i$, for $i \in N_T$ by our construction of $q^N$, and the estimates (2.35) and (2.36) in the last step. Similarly, we also have

$$(2.40) \quad \sum_{i \in N_T} \int_{B_i} |k_i^S q_i^S|^2 \, dx \leq C_{q^S}^2 \left[ \sum_{i \in N_T} |r_i^N|^2 + \sum_{i \in N_N} |r_i^N|^2 + \int_{\Omega} (r^D)^2 \, dx \right]$$

with $C_{q^S}^2 = \frac{2C_{kS}}{\epsilon^2} (C_N + C_D + 1)$.

Finally, we consider the following mixed-formulation Laplacian problem

$$(2.41) \quad (k^D)^{-1} q^D + \nabla \psi = 0$$

$$(2.42) \quad \nabla \cdot q^D = r^D + \sum_{i \in N_T} k_i^S q_i^S$$

with boundary condition $q^D \cdot n = 0$ on $\partial \Omega$. This problem is well-posed because

$$\int_{\Omega} r^D \, dx + \sum_{i \in N_T} \int_{B_i} k_i^S (x) q_i^S (x) \, dx$$

$$= \int_{\Omega} r^D \, dx + \sum_{i \in N_T} \int_{B_i} k_i^S (x) \left( q_{N,i}^N + r_i^N \right) \, dx$$

$$= \int_{\Omega} r^D \, dx + \sum_{i \in N_T} \left( q_{N,i}^N + r_i^N \right)$$

$$= \int_{\Omega} r^D \, dx + \sum_{T \in F_N} \sum_{i \in N_T} \left( -r_i^N + \frac{1}{|N_{T,T}|} \int_{T} r^D \, dx - \frac{1}{|N_{F,D}|} \sum_{i \in N_{F,D}} r_i^N + r_i^N \right)$$

$$= 0,$$

which verifies the consistency of the data with respect to the pure Neumann boundary condition $q^D \cdot n = 0$ on $\partial \Omega$. Furthermore, the following estimate holds,

$$\int_{\Omega} |\nabla \cdot q^D|^2 \, dx \leq \int_{\Omega} |r^D|^2 + \sum_{i \in N_T} |k_i^S q_i^S|^2 \, dx$$

$$\leq 2 \int_{\Omega} |r^D|^2 \, dx + 2N_B \sum_{i \in N_T} \int_{B_i} |k_i^S q_i^S|^2 \, dx$$

$$(2.43) \quad \leq C_{q^D}^1 \left[ \int_{\Omega} |r^D|^2 \, dx + \sum_{i \in N_T} |r_i^N|^2 + \sum_{i \in N_{F,D}} |r_i^N|^2 \right]$$
where $C_{q,D}^1 = 2 \left( N_B, C_{q,S}^2 + 1 \right)$ and $N_B_i$ is the maximal number of the overlapping between the $B_i$, $i \in \mathcal{N}_T$. Similarly, we also have

$$
\int_\Omega (k_D)^{-1} |q_D|^2 \, dx \leq C_{p}^{-1} \int_\Omega |r_D| + \sum_{i \in \mathcal{N}_T} k_i^S q_i^S \, dx
$$

(2.44)

where $C_{q,D}^2 = C_{p}^{-1} C_{q,D}^1$ and $C_{p}$ is the weighted Poincare constant, i.e., $C_{p}(v,v) \leq (\langle k_D \nabla v, \nabla v \rangle)$. Now $[q^D, q^S, q^N]$ has been constructed based on $[r^D, r^N]$ and it satisfies

$$
\mathcal{D} \cdot [q^D, q^S, q^N] = [r^D, r^N],
$$

and we have

$$
\| [q^D, q^S, q^N] \|_{H^1(\mathcal{D})}^2 = \| [q^D, q^S, q^N] \|_{H^1(\mathcal{R}^+, 1)}^2 + \mathcal{D} \cdot [q^D, q^S, q^N] \|_{L^2}^2,
$$

(2.45)

$$
= \int_\Omega (k_D)^{-1} |q_D|^2 \, dx + \sum_{i \in \mathcal{N}_T} \int_{B_i} |q_i^S|^2 \, dx
$$

$$
+ \sum_{\epsilon(i,j) \in \mathcal{E}} (k_{\epsilon(i,j)}^N)^{-1} |q_{i,j}^N|^2 + \| [r^D, r^N] \|_{L^2}^2.
$$

Now, based on (2.37), (2.39), and (2.44), we can derive that

$$
\| [q^D, q^S, q^N] \|_{H^1(\mathcal{D})}^2 \leq C_{\beta} \| [r^D, r^N] \|_{L^2}^2,
$$

(2.46)

with $C_{\beta} = 2C_{q,D}^2 + 2C_{q,S}^1 + C_{q,N} + 1$. Then the inf-sup condition (2.30) hold with $\beta = C_{\beta}^{-1}$.

Remark 2.6. The inf-sup proof shows the importance of the using the scaled equations (2.20) and (2.21) in the case where $k_T$ goes to zero. Indeed, for the non-scaled equations, a similar approach would lead to an inf-sup constant depending on the pointwise lower bound on $\inf_{x \in B_i} (k_T^i(x))^{-1}$, which may not be positive. In contrast, as seen in the proof above, for the scaled equations, inf-sup constant depends on the much less restrictive integrated bound $c_{k_T^i}$.

Based on Lemmas 2.3, 2.4, and 2.5, we immediately have the following well-posedness results.

Theorem 2.7 (Well-posedness of (2.23)-(2.24)). The weak formulation (2.23) and (2.24) is well-posed with respect to the norms (2.26) and (2.25).

Proof. The result follows directly from the standard theory for saddle point problems, see, e.g. [6].

3. Finite-element Approximation. In this section, we propose the finite-element approximation for solving the weak formulation (2.23)-(2.24). The coupling between the graph and the porous domain, as well as the heterogeneous nature of the parameters found in applications, suggests that it is natural to consider low-order approximations. As a consequence, we only consider the lowest-order approximation here, recognizing that higher-order spaces can be introduced in the mixed formulation.
3.1. Mixed Finite-Element Method. Given a mesh $\mathcal{M}$ of the domain $\Omega$, e.g., triangles/quadrilaterals in 2D and tetrahedrons/cuboids in 3D, we consider the standard RT0/P0 finite element for approximating the fluid flux $q^D$ and pressure $P^D$ in the domain and denote them by $H_h(\text{div}, \mathcal{M})$ and $P_0(\mathcal{M})$, respectively. For node pressure potentials $p^N$, we use vertex degrees of freedom (DOFs) of the graph. For fluid flux on the tree edges, we use edge DOFs of the graph. For the fluid flux transferring from terminal $i$ to point $x$, it appears natural to consider the piecewise constant finite element on $\mathcal{M}_i$ (denoted as $P_0(\mathcal{M}_i)$), which is the restriction of $\mathcal{M}$ to $B_i$, i.e. $\mathcal{M}_i = \mathcal{M} \cap B_i$. In summary, we consider the following conforming finite-element spaces

\[ \mathcal{H}_h^0(\text{div}) := H_h(\text{div}, \mathcal{M}) \times \prod_{i \in \mathcal{N}_F} P_0(\mathcal{M}_i) \times L^2(\mathcal{E}) \subset \mathcal{H}(\text{div}), \]

its corresponding finite-element space with boundary conditions,

\[ \mathcal{H}_{h,0}^0(\text{div}) := H_{h,0}(\text{div}, \mathcal{M}) \times \prod_{i \in \mathcal{N}_F} P_0(\mathcal{M}_i) \times L^2(\mathcal{E}) \subset \mathcal{H}_0(\text{div}), \]

where $H_{h,0}(\text{div}, \mathcal{M}) := \{ q^D_h \in H_h(\text{div}, \mathcal{M}) \mid q^D_h \cdot n = 0, \text{ on } \partial \Omega \}$, and

\[ \mathcal{L}^2_h := P_0(\mathcal{M}) \times L^2(\mathcal{N}_E) \subset \mathcal{L}^2. \]

Using the finite-element spaces introduced above, the mixed finite-element approximation of (2.23)-(2.24) is: Find $q_h := [q^D_h, q^S_h, q^N_h] \in \mathcal{H}_{h,0}(\text{div})$ and $p_h := [p^D_h, p^N_h] \in \mathcal{L}^2_h$, such that

\begin{align*}
(3.1) & \quad (q_h, v_h)_{H^{-1}} - (p_h, \mathcal{D} \cdot q_h) = 0, \quad \forall v_h \in \mathcal{H}_{h,0}(\text{div}), \\
(3.2) & \quad - (\mathcal{D} \cdot q_h, w_h) = -(r, w_h), \quad \forall w_h \in \mathcal{L}^2_h.
\end{align*}

Remark 3.1. By considering a test function $w_h$ which is constant on a $B_i$, we verify from equations 2.17 and 2.18 that the physical flux $q^T = k_i^S q^S_i$ is conserved. We note that the lowest-order mixed finite element approximation is locally conservative even when applied to scaled variables, in contrast to the situation observed when similar scalings are applied in the physical dimensions of $\Omega$ (see e.g. [3]).

3.2. Well-posedness. In this subsection, we consider the well-posedness of the mixed finite-element approximation (3.1)-(3.2). It is essentially the same as the well-posedness analysis for the weak formulation in Section 2.4.

Since we use conforming finite-element spaces, the continuity results (Lemma 2.3) holds naturally on the discrete level.

Lemma 3.2 (Continuity of (3.1)-(3.2)). For any $q_h, v_h \in \mathcal{H}_{h,0}(\text{div})$ and $w_h \in \mathcal{L}^2_h$, we have

\begin{align*}
(3.3) & \quad (q_h, v_h)_{H^{-1}} \leq \|q_h\|_{\mathcal{H}(\text{div})} \|v_h\|_{\mathcal{H}(\text{div})}, \\
(3.4) & \quad (\mathcal{D} \cdot q_h, w_h) \leq \|q_h\|_{\mathcal{H}(\text{div})} \|w_h\|_{\mathcal{L}^2}.
\end{align*}

For the ellipticity (Lemma 2.4), using the fact that the finite dimensional spaces are constructed such that for $q_h \in \mathcal{H}_{h,0}(\text{div})$, $\mathcal{D} \cdot q_h \in \mathcal{L}^2_h$, then the same result hold on the discrete level.

Lemma 3.3 (Ellipticity of (3.1)-(3.2)). If $q_h \in \mathcal{H}_h(\text{div})$ satisfies

\begin{align*}
(3.5) & \quad (\mathcal{D} \cdot q_h, w_h) = 0, \quad \forall w_h \in \mathcal{L}^2_h,
\end{align*}
then
\begin{equation}
(q_h, q_h)_{\Omega, 1} = \|q_h\|^2_{\mathcal{B}(\text{div})}
\end{equation}

Moreover, the inf-sup condition (Lemma 2.5) can be derived in a similar fashion on the discrete level as well.

**Lemma 3.4** (Inf-sup condition of (3.1)-(3.2)). There exists a constant \(\beta > 0\) such that, for any given function \(r_h \in \Omega_h^2\),
\begin{equation}
\sup_{q_h \in \mathcal{B}_{h,0}(\text{div})} \left( r_h, \mathcal{D} \cdot q_h \right) \geq \beta \|r_h\|_{L^2}.
\end{equation}

Here, the inf-sup constant \(\beta\) depends on \(|M_i| = \text{measure}(M_i) = \mathcal{O}(h^n)\), the maximal number of overlaps between \(B_i\), structure of the trees \(T \in \mathcal{F}\), the domain \(\Omega\), and the constants \(c_{kS}\) and \(C_{kS}\).

**Proof.** Given \([r^D_h, r^N_h] \in \Omega_h^2\), the construction of \([q^D_h, q^S_h, q^N_h] \in \mathcal{B}_{h,0}(\text{div})\) is similar to the construction presented in the proof of Lemma 2.5. \(q^N_h\) can be constructed exactly the same as the construction of \(q^N\). Then \(q^S_h\) can be defined as (2.38) as well since such construction also makes sure that \(\mathcal{D} \cdot [q^D_h, q^S_h, q^N_h] = [r^D_h, r^N_h]\), and
\begin{equation}
\| [q^D_h, q^S_h, q^N_h] \|_{\mathcal{B}(\text{div})} \leq C_{\beta} \| [r^D_h, r^N_h] \|_{L^2}.
\end{equation}

Therefore the inf-sup condition (3.5) follows directly.

Thus, the well-posedness of the mixed finite-element approximation (3.1)-(3.2) follows from Lemmas 3.2, 3.3, and 3.4.

**Theorem 3.5** (Well-posedness of (3.1)-(3.2)). The weak formulation (3.1) and (3.2) is well-posed with respect to the norms (2.26) and (2.25).

**3.3. Convergence.** Based on Lemma 3.2, 3.3, and 3.4 and applying the general theory of Galerkin methods, we immediately gives a quasi-optimality error estimate.

**Theorem 3.6.** Suppose that \(q \in \mathcal{B}_0(\text{div})\) and \(p \in \Omega^2\) satisfy the weak formulation (2.23)-(2.24), then the finite-element solution \(q_h \in \mathcal{B}_{h,0}(\text{div})\) and \(p_h \in \Omega_h^2\) of the mixed finite-element approximation (3.1)-(3.2) satisfy that
\begin{equation}
\|q - q_h\|_{\mathcal{B}(\text{div})} + \|p - p_h\|_{L^2} \leq c \left( \inf_{v_h \in \mathcal{B}_{h,0}(\text{div})} \|q - v_h\|_{\mathcal{B}(\text{div})} + \inf_{w_h \in \Omega_h^2} \|p - w_h\|_{L^2} \right),
\end{equation}

where the constant \(c\) depends on \(\beta\).

As usual, to obtain the final convergence result, we use interpolations to bound the right-hand-side of the above error estimate (3.6). Here, we choose \(v^D_h = \pi_{\text{div}} q^D\), where \(\pi_{\text{div}} : H^1(\Omega) \mapsto \)
**MIXED-DIMENSIONAL PROBLEMS WITH HIGH DIMENSIONAL GAP**

$H_h(\text{div}, M)$ is the standard interpolation given by the $H_h(\text{div}, M)$ degrees of freedom, $v_h^S = \pi_0 q^S$, where $\pi_0$ denotes the standard piecewise constant interpolation, and $v_h^N = q^N$. With those choices and the classical error estimates for interpolations, together with Cauchy-Schwarz inequality, we naturally have

$$
\| [q^D, q^S, q^N] - [\pi_{\text{div}} q^D, \pi_0 q^S, q^N] \|_{H(\text{div})} \leq c h \left( \| q^D \|_1 + \| \nabla \cdot q^D \|_1^2 + \sum_{i \in N_T} \| q^S_i \|_1 \right)^{1/2}.
$$

Similarly, by choosing $w_h^D = \pi_0 p^D$ and $w_h^N = p^N$, we have

$$
\| [p^D, p^N] - [\pi_0 p^D, p^N] \|_{L^2} \leq c h \| p^D \|_1.
$$

Therefore, we have the overall convergence result for the finite-element method (3.1)-(3.2) as follows.

**Corollary 3.7.** Suppose that $q \in H_0(\text{div})$ and $p \in L^2$ satisfy the weak formulation (2.23)-(2.24), then the finite-element solution $q_h \in H_{h,0}(\text{div})$ and $p_h \in L^2$ of the mixed finite-element approximation (3.1)-(3.2) satisfy that

$$
\| q - q_h \|_{H(\text{div})} + \| p - p_h \|_{L^2} \leq c h \left( \| q^D \|_1 + \| \nabla \cdot q^D \|_1^2 + \sum_{i \in N_T} \| q^S_i \|_1 + \| p^D \|_1 \right),
$$

where the constant $c$ depends on $\beta$ and the quasi-uniformity of the mesh $M$.

**Remark 3.8.** In Corollary 3.7, we require $\nabla \cdot q^D \in H_1(\Omega)$ because the convergence analysis is derived by following the standard Babuška-Brezzi theory. As it is well-known for the error analysis of the fixed-dimensional mixed finite-element method for second-order elliptic problem, this regularity requirement can be relaxed in the mixed-dimensional setting as well, i.e., we have the following error estimates

$$
\| q - q_h \|_{H(\text{div})} + \| p - p_h \|_{L^2} \leq c h \left( \| q^D \|_1 + \| r^D \|_1 + \sum_{i \in N_T} \| q^S_i \|_1 + \| p^D \|_1 \right),
$$

Due to space constraints, we omit the derivation here but comment that it is essentially the same as the derivation for the fixed-dimensional case as shown in [6].

4. **Mass Lumping and Two-Point Flux Approximation Scheme.** In practice, when the triangulation of the domain $\Omega$ is uniform, it is possible to simply the discretization scheme and use two-point flux approximation (TPFA) to discretize the PDE system given by the conservation laws (2.17), (2.2), (2.18) and the constitutive laws (2.4), (2.5), (2.19). This is particularly relevant for medical applications, where the data is frequently specified on voxels (i.e. regular Cartesian grids in 3D).

In this section, we, therefore, discuss the TPFA scheme for our coupled Network-Darcy model through its relationship with the mixed finite-element approximation (3.1) and (3.2) discussed in Section 3.

4.1. **TPFA Scheme.** On a given mesh $M$, similar to standard diffusion problems, the TPFA scheme can obtained by applying mass lumping to the mixed finite-element scheme (3.1)-(3.2) and
then eliminating the flux $q_h$. To this end, we define the following inner product on the finite element spaces $\mathcal{H}_h(\text{div})$, for $q_h$ and $v_h \in \mathcal{H}_h(\text{div}),$

$$
(q_h, v_h)_{\mathcal{H}_h^{-1}, h} := \sum_{\tau \in \mathcal{M}} \int_{\partial \tau} \omega_f (q^D \cdot n_f) (v^D \cdot n_f) + \sum_{i \in \mathcal{N}_T} \int_{B_i} q^S_i v^S_i \, dx + \sum_{e(i,j) \in \mathcal{E}} (k^N_{e(i,j)})^{-1} q^N_{i,j} v^N_{i,j},
$$

(4.1)

where $\omega_f = (k^D)^{-1} \frac{d_f}{|\tau|}$ with $k^D$ being the average of $k^D$ on the element $\tau \in \mathcal{M}$ and $d_f$ being the distance between the face $f \in \partial \tau$ and the cell center of $\tau$. Now we define the mass lumping finite-element scheme as follows: Find $q_h \in \mathcal{H}_h,0(\text{div})$ and $p_h \in \mathcal{L}^2_h$, such that,

$$
(q_h, v_h)_{\mathcal{H}_h^{-1}, h} - (p_h, \nabla \cdot v_h) = 0, \quad \forall v_h \in \mathcal{H}_h,0(\text{div}),
$$

(4.2)

$$
-(\nabla \cdot q_h, w_h) = -(r, w_h), \quad \forall w_h \in \mathcal{L}^2_h.
$$

(4.3)

Based on the inner product (4.1), we define a discrete gradient $\mathbf{\nabla}_h : \mathcal{L}^2_h \rightarrow \mathcal{H}_h(\text{div})$ via integration by part (Lemma 2.2), for any $v_h \in \mathcal{H}_h(\text{div})$ and $p_h \in \mathcal{L}^2_h$, such that,

$$
(\mathbf{\nabla}_h p_h, v_h)_{\mathcal{H}_h^{-1}, h} := -(p_h, \nabla \cdot v_h) + \int_{\partial \Omega} p^D_h v^D_h \cdot n \, dx + \sum_{i \in \mathcal{N}_D} (p^N_h)_i (v^N_h)_{N_i,i}.
$$

Note that, due to the boundary conditions, $p^D_h \cdot n = 0$ on $\partial \Omega$ and $(p^N_h)_i = 0, i \in \mathcal{N}_D$, we simply have $(\mathbf{\nabla}_h p_h, v_h)_{\mathcal{H}_h^{-1}, h} = -(p_h, \nabla \cdot v_h)$. Then the mass lumping mixed-formulation (4.2) and (4.3) can be written as, find $q_h \in \mathcal{H}_h,0(\text{div})$ and $p_h \in \mathcal{L}^2_h$, such that,

$$
(q_h, v_h)_{\mathcal{H}_h^{-1}, h} + (\mathbf{\nabla}_h p_h, v_h)_{\mathcal{H}_h^{-1}, h} = 0, \quad \forall v_h \in \mathcal{H}_h,0(\text{div}),
$$

$$
(\mathbf{\nabla}_h w_h, q_h)_{\mathcal{H}_h^{-1}, h} = -(r, w_h), \quad \forall w_h \in \mathcal{L}^2_h.
$$

The above formulation allows us to eliminate $q_h$ and obtain the TPFA scheme as follows, find $p_h \in \mathcal{L}^2_h$, such that

$$
(\mathbf{\nabla}_h p_h, \mathbf{\nabla}_h w_h)_{\mathcal{H}_h^{-1}, h} = (r, w_h), \quad \forall w_h \in \mathcal{L}^2_h.
$$

(4.4)

Next we will explain the TPFA scheme (4.4) using matrix notation. The matrix form of the mass lumping finite-element scheme (4.2)-(4.3) can be written as

$$
\begin{pmatrix}
D_D & 0 & 0 & G_{DD} & 0 \\
0 & D_S & 0 & G_{SD} & G_{SN} \\
0 & 0 & D_N & 0 & G_{NN} \\
G_{DD}^T & G_{SD}^T & 0 & 0 & 0 \\
0 & G_{SN} & G_{NN}^T & 0 & 0
\end{pmatrix}
\begin{pmatrix}
q^D_h \\
p^D_h \\
p^N_h \\
p^N_h \\
p^N_h
\end{pmatrix}
= \begin{pmatrix}
0 \\
0 \\
r^D \\
r^N
\end{pmatrix},
$$

where

$$
\sum_{\tau \in \mathcal{M}} \sum_{f \in \partial \tau} \omega_f (q^D \cdot n_f) (v^D \cdot n_f) \mapsto D_D, \quad \sum_{i \in \mathcal{N}_T} \int_{B_i} q^S_i v^S_i \, dx \mapsto D_S, \quad \sum_{e(i,j) \in \mathcal{E}} (k^N_{e(i,j)})^{-1} q^N_{i,j} v^N_{i,j} \mapsto D_N.
$$
- \int_{\Omega} p^D \nabla \cdot v^D \, dx \mapsto \mathcal{G}_{DD}, \quad \sum_{i \in \mathbb{N}_T} \int_{B_i} k_i^S v_i^S p^D \, dx \mapsto \mathcal{G}_{SD}, \\
abla \cdot \left( \int_{B_i} k_i^S v_i^S \, dx \right) p_i^N \mapsto \mathcal{G}_{SN}, \text{ and } \sum_{i \in \mathbb{N}_T \cup \mathbb{N}_N} \left( \sum_{j \in \mathbb{N}_i} v_{j,i}^N \right) p_i^h + \sum_{i \in \mathbb{N}_T} v_{N,i}^N p_i^N \mapsto \mathcal{G}_{NN}.

Since \( D, D_s, \) and \( D_N \) are diagonal matrices, we can eliminate them by block Gaussian elimination and end up with a linear system only involving solving for \( p_h^D \) and \( p_h^N \) as follows,

\[
\begin{pmatrix}
G_{DD}^T & 0 \\
0 & G_{SN}^T
\end{pmatrix}
\begin{pmatrix}
D_D & 0 & 0 \\
0 & D_S & 0 \\
0 & 0 & D_N
\end{pmatrix}
^{-1}
\begin{pmatrix}
G_{DD} & 0 \\
G_{SD} & G_{SN} \\
0 & G_{NN}
\end{pmatrix}
\begin{pmatrix}
p_h^D \\
p_h^S \\
p_h^N
\end{pmatrix}
= \begin{pmatrix}
r_h^D \\
r_h^S \\
r_h^N
\end{pmatrix},
\]

which is exactly the matrix form of the TPFA scheme (4.4).

4.2. Well-posedness. Next we consider the well-posedness of the TPFA scheme (4.4). As we showed in the previous section, the TPFA scheme (4.4) is obtained from the mass lumping mixed-formulation (4.2)-(4.3) by block Gaussian elimination. Therefore, we first show the well-posedness of the mass lumping mixed-formulation (4.2)-(4.3) and then the well-posedness of the TPFA scheme (4.4) follows directly.

Since the only difference between the mixed-formulation (3.1)-(3.2) and the mass lumping mixed-formulation (4.2)-(4.3) is the inner product used for TPFA scheme (4.4) follows directly.

Since the only difference between the mixed-formulation (3.1)-(3.2) and the mass lumping mixed-formulation (4.2)-(4.3) is the inner product used for \( \mathcal{H}_h(\text{div}) \), we first introduce the norm induced by the inner product (4.1) as follows,

\[
\| q_h \|_{\mathcal{H}_h(\text{div})}^2 := (q_h, q_h)_{\mathcal{H}_h(\text{div})}, \quad \forall q_h \in \mathcal{H}_h(\text{div}),
\]

and show it is spectrally equivalent to the norm (2.27) in the following lemma.

**Lemma 4.1.** For any \( q_h \in \mathcal{H}_h(\text{div}) \), we have

\[
(4.5) \quad c_1 \| q_h \|_{\mathcal{H}_h(\text{div})}^2 \leq \| q_h \|_{\mathcal{H}_h(\text{div})}^2 \leq c_2 \| q_h \|_{\mathcal{H}_h(\text{div})}^2,
\]

where \( c_1 > 0 \) and \( c_2 > 0 \) are constants only depending on the shape regularity of the mesh \( \mathcal{M} \).

**Proof.** Based on the standard result, e.g., [13], we have

\[
\tilde{c}_1 \sum_{\tau \in \mathcal{M}} \sum_{f \in \partial \tau} \omega_f (q_h^D \cdot n_f)^2 \leq \int_{\Omega} (k^D)^{-1} |q_h^D|^2 \, dx \leq \tilde{c}_2 \sum_{\tau \in \mathcal{M}} \sum_{f \in \partial \tau} \omega_f (q_h^D \cdot n_f)^2
\]

where the positive constants \( \tilde{c}_1 \) and \( \tilde{c}_2 \) depend only the shape regularity of the mesh \( \mathcal{M} \). Then the spectral equivalence (4.5) follows directly from the definitions of the norms. \( \square \)

Define

\[
(4.6) \quad \| q_h \|_{\mathcal{H}_h(\text{div})} := \| q_h \|_{\mathcal{H}_h(\text{div})} + \| \mathcal{D} \cdot q_h \|_{L^2}.
\]

We have the following lemmas concerning the continuity, ellipticity, and inf-sup condition for the mass lumping mixed-formulation (4.2)-(4.3).

**Lemma 4.2.** (Continuity of (4.2)-(4.3)). For any \( q_h, v_h \in \mathcal{H}_h(\text{div}) \) and \( w_h \in L^2_h \), we have

\[
(q_h, v_h)_{\mathcal{H}_h(\text{div})} \leq \| q_h \|_{\mathcal{H}_h(\text{div})} \| v_h \|_{\mathcal{H}_h(\text{div})},
\]

\[
(\mathcal{D} \cdot q_h, w_h) \leq \| q_h \|_{\mathcal{H}_h(\text{div})} \| w_h \|_{L^2}.
\]
For the ellipticity, again using the fact that, for \( q_h \in \mathcal{S}_h(\text{div}) \), we have

**Lemma 4.3 (Ellipticity of (4.2)-(4.3)).** If \( q_h \in \mathcal{S}_h(\text{div}) \) satisfies

\[
(\mathcal{D} \cdot q_h, w_h) = 0, \quad \forall w_h \in \mathcal{L}^2_h,
\]

then

\[
(q_h, q_h)^{R-1}_h = \|q_h\|^2_{\mathcal{S}_h(\text{div})}
\]

Moreover, the inf-sup condition can be derived from the inf-sup condition (Lemma 3.4) and the spectral equivalence lemma (Lemma 4.1)

**Lemma 4.4 (Inf-sup condition of (4.2)-(4.3)).** There exists a constant \( \beta > 0 \) such that, for any given function \( r_h \in \mathcal{L}^2_h \),

\[
\sup_{q_h \in \mathcal{S}_h(\text{div})} \frac{(r_h, \mathcal{D} \cdot q_h)}{\|q_h\|_{\mathcal{S}_h(\text{div})}} \geq \beta \|r_h\|_{\mathcal{L}^2}.
\]

Here, the inf-sup constant \( \beta \) depends on \( |\mathcal{M}_i| = \text{measure}(\mathcal{M}_i) = O(h^n) \), the maximal number of overlaps between \( B_i \), structure of the trees \( T \in \mathcal{T} \), the domain \( \Omega \), the constants \( c_k \) and \( C_k \), and the shape regularity of the mesh \( \mathcal{M} \).

**Proof.** The inf-sup condition (4.7) can be derived from the inf-sup condition (3.5) and the spectral equivalence result (4.5).

Now the well-posedness of the mass lumping mixed formulation (4.2) and (4.3) follows from Lemmas 4.2, 4.3, and 4.4.

**Theorem 4.5 (Well-posedness of (4.2)-(4.3)).** The mass lumping mixed formulation (4.2)-(4.3) is well-posed with respect to the norms (4.6) and (2.25).

Finally, the well-posedness of the TPFA scheme (4.4) follows directly from Theorem (4.5) and the equivalence between the TPFA scheme (4.4) and the mass lumping mixed-formulation (4.2)-(4.3). The result is summarized in the following theorem.

**Theorem 4.6 (Well-posedness of (4.4)).** The TPFA scheme (4.4) is well-posed.

### 4.3. Convergence

Regarding the convergence result of the TPFA scheme, since we use mass-lumping technique to derive it, existing theoretical tools developed in [4, 9] can be adopted here. For the sake of the simplicity, in this subsection, we assume that \( k^D \) is constant on each element \( \tau \in \mathcal{M} \) and the mesh \( \mathcal{M} \) is uniform (e.g., rectangle/equilateral triangle in 2D, rectangular cuboid/regular tetrahedra in 3D). Under those conditions, as shown in [4], for \( \tau \in \mathcal{M} \),

\[
\sum_{f \in \partial \tau} \omega_f (q^D \cdot n_f) (v^D \cdot n_f)
\]

used in the definition (4.1) provides a numerical integration formula of \( \int_\tau (k^D)^{-1} q^D v^D \, dx \) and such a numerical integration is exact for constant functions on each element \( \tau \). Moreover, the following perturbation result holds for \( q^D, v^D \in \mathcal{H}_{h,0}(\text{div}, \mathcal{M}) \),

\[
\int_\tau (k^D)^{-1} q^D v^D \, dx - \sum_{f \in \partial \tau} \omega_f (q^D \cdot n_f) (v^D \cdot n_f) \leq ch^2 \|q^D\|_{\mathcal{H}(\text{div}, \tau)} \|v^D\|_{\mathcal{H}(\text{div}, \tau)}.
\]

Based on the above result, we can easily verify that, for \( q_h, v_h \in \mathcal{S}_h(\text{div}) \),

\[
|(q_h, v_h)^{R-1} - (q_h, q_h)^{R-1}_h| \leq ch^2 \|q_h\|_{\mathcal{S}_h(\text{div})} \|v_h\|_{\mathcal{S}_h(\text{div})}.
\]
Now, we can use the theory developed in [27] and conclude the convergence result of the TPFA scheme in the following theorem.

**Theorem 4.7.** Suppose that \( q \in H^0(\text{div}) \) and \( p \in L^2 \) satisfy the weak formulation (2.23)-(2.24), then the finite-element solution \( q_h \in H^0(\text{div}) \) and \( p_h \in L^2 \) of the mass lumping mixed finite-element approximation (4.2)-(4.3) satisfy that

\[
\|q - q_h\|_{H^0(\text{div})} + \|p - p_h\|_{L^2} \leq ch \left( \|q^D\|_1 + \|\nabla \cdot q^D\|_1 + \sum_{i \in N_T} \|q^S_i\|_1 + \|p^D\|_1 \right)
\]

where the constant \( c \) depends only on \( \beta, k^D \), the maximal number of the overlap between \( M_i \), \( \max_i \{|M_i|\} \), and quasi-uniformity of the mesh \( \mathcal{M} \).

Consequentially, this also implies the convergence result of the TPFA scheme because of the equivalence between the TPFA scheme (4.4) and the mass lumping mixed formulation (4.2) and (4.3).

**Remark 4.8.** As pointed out in Remark 3.8, the regularity requirement \( \nabla \cdot q^D \in H^1(\Omega) \) can be relaxed here as well and similar convergence analysis still holds.

**Remark 4.9.** As shown in [4, 9], similar results hold for some more general meshes. For example, the perturbation result (4.8) hold for general triangles in 2D with order \( h \) instead of order \( h^2 \). However, this still leads to the error estimate (4.9) based on the same procedure. For general triangulation in 3D, convergence analysis for standard mixed formulation Poisson problem with mass lumping was derived based on a different approach in [9]. We can also adopt a similar approach to derive the convergence result for our mass lumping mixed finite-element scheme as well to obtain the error estimate (4.9) for general triangulation as well.

5. Linear Solvers. In this section, we discuss how to solve the linear systems obtained by three different discretizations, the mixed-formulation (3.1)-(3.2), the mass lumping mixed-formulation (4.2)-(4.3), and the TPFA scheme (4.4). The first two discretizations solve for both flux unknowns \( q_h = [q^D_h, q^S_h, q^N_h] \) and pressure unknowns \( p_h = [p^D_h, p^N_h] \), which leads to a two-by-two block structure naturally. Therefore, we design block preconditioners for those two cases. On the other hand, the TPFA scheme solves the unknown \( p_h \) first and then the unknowns \( q_h \) can be recovered. Therefore, we discuss multigrid methods for the TPFA scheme. In this section, we will solely be dealing with the discrete system, and thus omit the subscripts on \( q_h \) and \( p_h \).

5.1. Mixed-formulation (3.1)-(3.2). Let \( M_q \) and \( G \) be the matrix representations of the bilinear forms \((q, v)_K\) and \(-(p, \mathcal{D} \cdot v)_K\), respectively, then the matrix form of the mixed-formulation (3.1)-(3.2) can be written as follows

\[
\mathbb{A}_{\mathbf{r}} = f \iff \begin{pmatrix} M_q & G \\ \mathcal{G}^T & 0 \end{pmatrix} \begin{pmatrix} q \\ p \end{pmatrix} = \begin{pmatrix} 0 \\ \mathbf{r} \end{pmatrix}.
\]

Based on the two-by-two block from (5.1), it is natural to design block preconditioners. Here, we follow the framework developed in [25, 23, 24, 2] and develop robust preconditioners based on the well-posedness result, i.e., Theorem 3.5. Based on the theory developed in [25, 23], the norm-equivalent block preconditioner should be the Reisz operator corresponding to the norms (2.26) and (2.25), therefore, its matrix representation is

\[
\mathbb{B}_D = \begin{pmatrix} (M_q + \mathcal{G}M_p^{-1}\mathcal{G}^T) & 0 \\ 0 & M_p \end{pmatrix}^{-1}.
\]
where $\mathbf{M}_p$ is the matrix representation of $(p, w)$. Based on the well-posedness (Theorem 3.5), it can be shown that the condition number of the preconditioned system satisfies $\kappa(\mathbf{BA}) = O(1)$ and the hidden constant depends on the inf-sup constant $\beta$ but does not depend on the discretization parameter $h$ or physical parameters such as $k^D$ and $k^N$. This implies that the norm-equivalent preconditioner $\mathbf{B}_D$ is robust.

Field-of-value (FoV)-equivalent preconditioners can be derived in the same fashion following the framework developed in [23, 24, 2]. They are the block triangular type preconditioners as follows,

\[
\mathbf{B}_L = \left( (\mathbf{M}_q + \mathbf{G}^{-1}\mathbf{G}^T) \mathbf{0} \mathbf{M}_p \right)^{-1} \quad \text{and} \quad \mathbf{B}_U = \left( (\mathbf{M}_q + \mathbf{G}^{-1}\mathbf{G}^T) \mathbf{G} \mathbf{M}_p \right)^{-1}.
\]

The above block preconditioners can be used as preconditioners for the general minimal residual (GMRes) method and, following [24, 2], it can be shown that the preconditioned GMRes method converges robustly as well.

**5.2. Mass Lumping Mixed-formulation (4.2)-(4.3).** For the mass lumping case, the norm-equivalent and FoV-equivalent preconditioners can be derived in the same fashion by following the same framework. For the sake of simplicity, we only present the block preconditioners here.

Let $\mathbf{D}_q$ denote the matrix corresponding to $(q, v)_{k^{-1}, h}$, which is the mass lumping version of the matrix $\mathbf{M}_q$. Then the matrix form of the mass lumping mixed-formulation (4.2)-(4.3) is

\[
(\mathbf{D}_q + \mathbf{G}^{-1}\mathbf{G}^T) \mathbf{0} \mathbf{M}_p = \mathbf{r}.
\]

Based on Theorem 4.5, the norm-equivalent preconditioner is

\[
\mathbf{B}_D = \left( (\mathbf{D}_q + \mathbf{G}^{-1}\mathbf{G}^T) \mathbf{0} \mathbf{M}_p \right)^{-1}.
\]

And the FoV-equivalent preconditioners are

\[
\mathbf{B}_L = \left( (\mathbf{D}_q + \mathbf{G}^{-1}\mathbf{G}^T) \mathbf{0} \mathbf{M}_p \right)^{-1} \quad \text{and} \quad \mathbf{B}_U = \left( (\mathbf{D}_q + \mathbf{G}^{-1}\mathbf{G}^T) \mathbf{0} \mathbf{M}_p \right)^{-1}.
\]

As before, those block preconditioners can be used as preconditioners for GMRes methods.

**5.3. TPFA scheme 4.4.** For the TPFA scheme (4.4), following the discussion in Section 4.1, it can be obtained by block Gaussian elimination of the mass lumping mixed-formulation, i.e., its compact matrix form is

\[
\mathbf{G}^T(\mathbf{D}_q)^{-1}\mathbf{G} = \mathbf{r}.
\]

As we can see, this is a discretization of a Poisson type problem for the unknown $p$ in the mixed-dimensional setting. Since multigrid (MG) methods are designed for solving diffusion type problems efficiently [28, 30], in our work, we use an algebraic variant of the MG methods to solve the resulting linear system. More precisely, we use the aggregation-based AMG method, which is a suitable choice for solving both Poisson-type problems, see [5, 17], and graph Laplacian problems, see [10, 22, 15].
6. Numerical Results. In this section, we include three numerical results to validate and explore the discretization and solver presented above. In particular, the first case contains the simplest possible geometry in 2D, on which we compare the discretization to a series solution (Bessel functions). In the second case, we have a more complex geometry embedded in 4D, which can be seen as a prototype of the geometries relevant for applications. In both the first and second cases, we perform convergence studies both for the discretization and multigrid solver. Finally, in the third case, we apply the methodology to a real dataset, based on the human brain.

The error is measured in the norms proposed in the analysis, in particular we measure the $L^2$ norm of pressure and the $k^{-1/2}$-weighted norm of flux. As is common for finite volume and mixed finite-element methods, we use cell-centered quadrature when evaluating the $L^2$ norm in the domain, which allows us to exhibit the usual super-convergence behavior for these methods on smooth problems.

Due to the prevalence of image data for the applications of interest, all the numerical experiments are conducted on uniform Cartesian grids and the TPFA scheme is used. To solve the linear system (5.3), we use algebraic multigrid (AMG) preconditioned flexible GMRes (FGMRes) method. Here, an unsmoothed aggregation AMG method is used as the preconditioner. More precisely, one step of V-cycle AMG method is applied with one step of Gauss-Seidel method for both pre- and post-smoothing. The FGMRes method is terminated when the $\ell^2$-norm of the initial residual is reduced by a factor of $10^{-6}$. The implementations are in Matlab, and code is available from the authors on request. All runs are conducted on a Linux workstation using 40 Intel Xeon CPU processors (E5-2698 v4) at 2.20GHz clock speed, with 256 Gb RAM.

6.1. Case 1: Comparison to Convergent Series Solution. Our first case is constructed such that a series solution (in terms of well-known Bessel functions) is available. The full derivation of the series solution is available in the Appendix, an illustration of the geometry, and the series solution is provided in Figure 2. Throughout this subsection, we consider the series solution as the exact solution of the equations, since arbitrary precision can be obtained using well-established implementations of table values [1].

![Illustration of domain for Case 1](image1)

**Fig. 2.** Left: Illustration of domain for Case 1, with transfer function $k^T$ (red) and source term $r^D$ (blue). The source term, which is actually a sink in this setup, has been scaled by $10^2$ for visualization purposes. Right: Illustration of pressure (black) and radial flux (grey) in the domain as function of distance from the origin. Note that for the pressure, we have plotted $p^D(r) - p^D(0.5)$ in order to facilitate visual comparison. In both figures, cases 1A is represented by solid lines and 1B by dashed-dotted lines.
The main features of the solution is a simple two-node tree, where node 0 is a Dirichlet boundary node, and node 1 is a terminal node. Correspondingly, there is a single edge in the network, which contains the network flux. The solution is constructed with a transfer function \( k^T \) that has compact support on a disc of radius \( r_1 \) from the origin. We consider two variants of the case, case 1A has a smoothly degenerating transfer function such that (in terms of radial coordinates) \( k^T(r) \rightarrow 0 \) as \( r \rightarrow r_1 \), while case 1B has a constant \( k^T \) within the disc (and zero outside), thus \( k^T \sim H(r_1 - r) \), where \( H \) denotes the Heaviside function. To drive the system, a quadratic source term is provided in the region \( r_2 < r \leq r_3 \).

We conduct numerical experiments with unit values, such that the domain \( \Omega \) is the unit square centered at the origin, the domain and network permeabilities are unit valued, and the scaling of source term \( r^D_\text{D} = 1 \). The transfer function \( k^T \) has a unit maximum value at the origin, for both case A and B, as stated, we consider two versions of the case. For the case 1A, we consider a degenerating transfer function \( k^T \), with \( r_0 = 0.2, r_1 = 0.3, r_2 = 0.3, r_3 = 0.4 \). For case 1B, we let the transfer function abruptly go to zero by keeping all radii as in case 1A, except for \( r_0 = 0.2 \).

An important aspect of the implementation is the accuracy with which the right-hand-side and the inner products involving \( k^S \) are evaluated. In the results reported here, we have used a fourth-order accurate numerical quadrature.

The convergence results of cases 1A and 1B are presented in Table 1 and 2. We show the convergence history separated into components similar to the analysis, i.e. Domain, Scaled terminal flux, and Network.

First note that for this example, since the network contains a single throat and the domain has Neumann boundary conditions, global conservation of mass implies that \( q^N_h \) will be exact up to the quadrature error in the evaluation of \( r^D \), and similarly for \( p^N_h \). Thus the fourth-order convergence of these variables is expected.

As for the remaining variables, we observe in both Case 1A and Case 1B optimal second-order convergence of \( p^D_h \) and first-order convergence of \( q^D_h \). In this example, the scaled terminal flux \( q^S_h \) is essentially just the weighted difference between \( p^D_h \) and \( p^N_h \), and thus it inherits the (slower) convergence rate of the two, i.e. second-order. By comparing the two cases, we see that there is no influence of the degeneracy of \( k^S \).
MIXED-DIMENSIONAL PROBLEMS WITH HIGH DIMENSIONAL GAP

Table 3

The performance of the iterative solver for Case 1A is summarized in Table 3. The results for Case 1B are essentially identical and are omitted (the deviation is less than 5% in all quantities). This test case, due to the simplicity of the network, is from a linear algebra perspective almost identical to the 2D homogeneous Poisson problem. Therefore, the aggregation-based AMG preconditioner performs as expected. Here, the grid complexity (GridComp.) is defined as the ratio between the total size of the matrices on different levels and the size of the matrix on the finest level. The operator complexity (Oper.Comp.) is defined as the ratio between the total number of nonzeros of the matrices on different levels and the number of nonzeros of the matrix on the finest level. As we can see, both Grid Complexity and Operator Complexity are bounded by 2, which means that the aggregation-based AMG method roughly preserves the sparsity on the coarse levels and the overall computational cost of one V-cycle AMG method is optimal (i.e. linearly proportional to the cost of one step of Gauss-Seidel method). Since we use a simple unsmoothed aggregation AMG method here, the number of iterations grows with respect to the size of the linear system as expected. Overall, the computational cost of the multilevel solver is sub-optimal. We want to point out that it is possible to obtain optimal computational complexity when a more sophisticated AMG cycle, such as the K-cycle is used [29, 16]. This is a subject of our ongoing and future research since developing special tailored multilevel solvers for mixed-dimensional problems is a challenging and important task itself and beyond the scope of this work.

6.2. Case 2: A Prototypical 4 Dimensional Case. Our second example is chosen to illustrate a typical case encountered in the modeling of tissue. The physical domain is 3-dimensional, however, due to the biomedical properties involved, the physical domain represents two or more continua (biomedically speaking, this corresponds to arterial and venal compartments, etc.). The
continua are ordered, and communication between the compartments is only allowed between neighbors in the ordering. As such, the continua represent a discretization of an elliptic equation in a fourth dimension. The mathematical structure of the resulting system is thus one of a 4D elliptic equation, coupled to networks, and is naturally covered by the methods proposed analyzed in this paper.

To explore this concept, and validate the performance of our methods, we consider the following concrete problem, as illustrated schematically in Figure 3. Let the model domain be the unit 4-cube. We consider Neumann boundary conditions on all faces of the domain. Furthermore, we consider two trees, which are named as "arterial tree" and "venous tree", respectively, to conform with applications and the next subsection. Each consists of four nodes connected in the shape of a "Y", wherein each tree one node is a Dirichlet boundary node ($p_{DN} = 1$ and $p_{DN} = 0$ in arterial and venous Dirichlet nodes, respectively), while two nodes are terminal nodes. The arterial terminal nodes $i$ are associated with transfer functions $k_T^a(x) = k_T^a(|x - y|_3)H(x_4 - 1/2)$, where $|x - y|_3 = \sum_{j=1}^3(x_j - y_{i,j})^2$ is the distance in the first three coordinates from the 3-points $y_i$, and $k_T^a$ are the transfer functions from Section 6.1 with $r_0 = 0.1$ and $r_1 = 0.2$. Conversely, the venous terminal nodes are associated with transfer functions $k_T^v(x) = k_T^v(|x - y|_3)H(x_4 - 1/2)$. For the arteries, the transfer functions are centered on 3-points $y_i$ defined by $[0.4, 0.25, 0.5]$ and $[0.4, 0.75, 0.5]$, while for the veins, the transfer functions are centered on $[0.6, 0.25, 0.5]$ and $[0.6, 0.75, 0.5]$

We discretize the domain with an anisotropic Cartesian grid in the sense that the first three dimensions are discretized by a regular isotropic Cartesian grid. The fourth dimension is discretized by only two grid cells. This resulting system is equivalent to the common two-compartment model, where the cells in the fourth dimension with $x_4 < 0.5$ correspond to the arterial compartment, and the remaining cells the venous compartment. In accordance with the practice in applications, we will emphasize grid refinement over model refinement, and only consider refinement of the first three dimensions. Moreover, we will in accordance with the applications decompose the domain flux into two parts $q^D \rightarrow [q^D, q^P]$, where the flux in the fourth dimension $q^P$ is referred to as "perfusion".

The convergence results for this case are presented in Table 4. All errors are reported relative to a numerical solution calculated with a resolution of $h = 256^{-1}$, and convergence rates are therefore reported for grids up to a resolution of $h = 128^{-1}$. As expected, we observe quasi-optimal convergence rates in all variables. In contrast to case 1, we no longer have the artificial exact solutions in the network, where we observe between first and second order convergence. Moreover, the super-convergence of the second-order super-convergence of pressure is lost, which we believe is due to the interaction with the (no longer exact) pressure at the terminal nodes.
MIXED-DIMENSIONAL PROBLEMS WITH HIGH DIMENSIONAL GAP

| Variable | 1/h | Error D | Rate D | Error T | Rate T | Error N | Rate N | Error P | Rate P |
|----------|-----|---------|--------|---------|--------|---------|--------|---------|--------|
| p        | 16  | 5.22e-04 | 0.00   | 1.38e-05 | 1.38e-05 | 6.81e-06 | 1.02   | 2.92e-07 | 2.75   |
|          | 32  | 3.19e-04 | 7.09e-01 | 0.00    | 1.97e-06 | 1.79   | 1.97e-06 | 1.79   |
|          | 64  | 1.26e-04 | 1.34   | 0.00    | 1.97e-06 | 1.79   | 1.97e-06 | 1.79   |
|          | 128 | 3.48e-05 | 1.86   | 0.00    | 2.92e-07 | 2.75   | 2.92e-07 | 2.75   |
| Average  |     | 1.30     | 1.30   | 1.30    | 1.30   | 1.30   | 1.30   | 1.30    | 1.30   |

Table 4
Convergence results for Case 2. All variables are reported as in table 1, with the (perfusion) flux in the fourth dimension additionally reported as $q^P$.

The solver results for this case are presented in Table 6, including the performance on the reference solution, which has more than 33 million degrees of freedom. Again, we observe that both grid complexity and operator complexity are bounded while the number of iterations grows sublinearly with respect to the size of the linear systems. This means the overall computational complexity is sub-optimal, which is expected since we are using a simple unsmoothed aggregation AMG preconditioner.

| 1/h | NLevel | GridComplexity | OperatorComplexity | NIter | CPUAMGsetup | CPUSolve |
|-----|--------|----------------|--------------------|-------|--------------|----------|
| 16  | 06     | 1.49e+00       | 1.75e+00           | 24    | 4.53e-02    | 6.35e-02 |
| 32  | 08     | 1.58e+00       | 1.93e+00           | 33    | 3.93e-01    | 5.39e-01 |

Table 5
Solver performance on Case 2.

6.3. Full-brain simulation study. As a final test case, we consider the application to a real data set, associated with blood flow in the human brain. The data-set and parameterization is described in detail in [14], and is illustrated in Figure 4. Here we only summarize the main features: the data contains two trees, corresponding to a segmentation of the arterial and venous systems, containing 355 and 1222 nodes, respectively. For the finest simulations, we consider the full resolution from the MRI acquisition, which is a Cartesian grid with $346 \times 448 \times 319$ grid cells, representing a brick-shaped field of view of $177 \times 224 \times 160$mm$^3$. The actual domain $\Omega$ is a 4D extrusion of the 3D subset of the field of view which contains the brain. Thus the mathematical formulation is a 4D model in the sense of the previous sub-section, and after discretizing the fourth dimension by two cells, the full model contains 17585494 grid cells. The domain $\Omega$ is furthermore segmented into two subdomains (anatomically: white matter $\Omega_{WM}$ and gray matter $\Omega_{GM}$), with permeability in the three physical dimensions set to an anisotropic value of $k^D = 10^{-12} m^2$. The permeability $k^D$ acting in the 4th dimension (anatomically: the perfusion coefficient), is in white matter set to $k^P = 10^{-6}$, $x \in \Omega_{WM}$, and in grey matter is set to $k^P = 1.6 \cdot 10^{-6}$, $x \in \Omega_{GM}$. The transfer permeability is set according to equation (7.1), with $r_1 = 30$mm, $r_0 = r_1/2$, and $k^T_0 = 1$. The edge flow $k^N$ is assigned individually for each edge based on Hagen-Poiseulle's law, using estimates of vessel diameter and vessel length measured in the binary vessel trees. Both arterial and venous trees are modeled with Dirichlet root nodes.
The full brain data contains many important quantitative properties, including the connectivity of the trees, and connectivity of the brain geometry. These properties ensuring well-posedness, as well as the representation of grey and white matter, are not trivially preserved when coarsening the data. Nevertheless, to investigate the solver performance we have constructed a series of coarsened data-sets. The actual solution sequences $q$ and $p$ on these coarser data-sets have poor approximation properties since the solution is not smooth with respect to these coarser scales (convergence is dominated by the regularity terms). Isolated sub-domains without source and/or sink terms can occur from the coarsening, leading to arbitrary scaling of the pressure within these regions. Thus we do not report convergence properties for this example, but limit our discussion to the stability of the discretization and the performance of the linear solver.

The computational performance of this case us summarized in Table 7. All results are reported relative to the discretization level of the data, which we label $h_0$. The results confirm that even for this large data-set, with data-driven and physiologically realistic parameters, the solver performs efficiently. The number of iteration grows sublinearly and the CPU time also indicates that the current solver is sub-optimal. However, we do not see the degradation of the AMG solver comparing with the previous two cases with simpler geometry, which demonstrates that our discretization is stable and solver-friendly. Moreover, the efficiency of the discretization and solver combinations proposed above allow for analysis of full-resolution medical data.

7. Conclusions. We have proposed a mixed-dimensional mathematical model, closely related to models used for modeling fluid flow in human vasculature. We show the well-posedness of this model on the continuous level and develop suitable numerical discretizations, of both mixed finite-element and finite volume types. These are shown to be stable and convergent. Furthermore, we
discuss suitable solvers for these methods.

Our theoretical results are complemented by numerical examples, which demonstrate superconvergence of the method in terms of the pressure variable on smooth solutions, and also verifies the stability and applicability of the method to large scale real-world data sets.

Appendix - Derivation of reference solution for section 6.1. The solution is valid for any domain $\Omega$ containing the origin and with zero Neumann boundary conditions, and for a tree consisting of two nodes: Node 0 is a Dirichlet node and node 1 is a terminal node. Please refer to Figure 2 for a visual illustration.

Setup. Consider polar coordinates $(r, \theta)$ around the origin, included in $\Omega$. In addition to Neumann boundary conditions on $\Omega$, the boundary pressure $p_{0}^{N}$ in the Dirichlet node is taken as a given, and we consider for simplicity zero source terms in the terminal node, $r_{1}^{N} = 0$.

Then we construct up to four concentric domains, bounded by $0 < r_{0} \leq r_{1} \leq r_{2} < r_{3} \leq \text{diam} (\Omega)$. The inner domain will be a disc, the remaining domains will be doughnuts. We consider homogeneous $k^{D} (\mathbf{x}) = k^{D}$, while the remaing parameters in $\Omega$ are strictly functions of $r$. In
particular, we choose a transfer permeability which is non-zero only in the two inner-most regions

\[
k^T(r) = k^T_0 \begin{cases} 
1 & \text{for } r \leq r_0, \\
\frac{a_0^2 r_1^2 - r_2^2}{r^2} & \text{for } r \leq r_1, \\
0 & \text{for } r > r_1.
\end{cases}
\]

Continuity of the transfer function at \( r_0 \) is obtained by setting

\[
a_0^2 = \frac{r_0^2}{r_1^2 - r_0^2}.
\]

The source is chosen as non-zero only between \( r_2 \) and \( r_3 \),

\[
r^D(r) = r^D_0 (r - r_2)^+ (r_3 - r)^+,
\]

where \((a)^+ = \max(0, a)\) indicates that only positive values are considered.

The governing equations in the domain \( \Omega \) can be stated in radial coordinates as (our parameters are radially symmetric, as will our solution be, and we drop \( \theta \) in the continuation):

\[
\frac{1}{r} \frac{d}{dr} \left( rd \frac{dp^D}{dr} \right) - q^T = r^D,
\]

where we recall that

\[
q^T = -k^T (p^D - p^N_1)
\]

**Solutions.** First, we note that by volume balance, we have that

\[
q^N \equiv q^N_0,1 = -2\pi r^D_0 \int_{r_2}^{r_3} r(r - r_2)(r_3 - r) = -2\pi r^D_0 \left( \frac{r_3^4 - r_2^4}{12} - r_2 r_3 \frac{r_3^2 - r_2^2}{6} \right).
\]

It then follows that the pressure \( p^N_1 \) at the terminal node is given by

\[
p^N_1 = p^N_0 - k^N q^N.
\]

The combination of equations (7.4) and (7.5) have analytical solutions within each region of the domain. These are as follows (these are reported in numerous text books, we will use Chapter 9 of Abramovich and Stegun as a concrete reference for the use and manipulation of Bessel functions [1]).

**Solution S1:** For \( r \leq r_0 \): By substitution of equation (7.5) into equation (7.4), we obtain

\[
r \frac{d}{dr} \left( r \frac{dp^D}{dr} \right) - \frac{k^T_0}{k^D} \frac{r^D}{r^2} (p^D - p^N_1) = 0,
\]

the solution of which is the modified Bessel function of the first kind \( I_0 \), since we easily determine that there is no singularity at the origin:

\[
p^D(r) - p^N_1 = c_I I_0(\kappa_0 r)
\]
where

\[(7.10) \quad \kappa_0 = \sqrt{\frac{k_T}{k_D}}\]

The constant \(c_I\) will be determined later. The derivative of pressure is obtained according to the differential rules for Bessel functions of integer order (see equation 9.6.27 in [1]):

\[(7.11) \quad I_0'_{|\kappa_0 r_0} = I_1(\kappa_0 r_0)\]

Thus the radial component of flux is given by

\[(7.12) \quad q^D = -k_D c_I \kappa_0 I_1(\kappa_0 r_0)\]

**Solution S2:** For \(r_0 < r \leq r_1\): By substitution of equation (7.5) into equation (7.4), we obtain in this region

\[(7.13) \quad r \frac{d}{dr} \left(r \frac{dp^D}{dr}\right) + \frac{k_T}{k_D} a_0^2 (r^2 - r_1^2)(p^D - p_1^N) = 0,\]

the solution of which are the (unmodified) Bessel functions of the first and second kind \(J\) and \(Y\), of fractional order:

\[(7.14) \quad p^D(r) - p_1^N = c_J J_{\kappa_1 r_1}(\kappa_1 r_1) + c_Y Y_{\kappa_1 r_1}(\kappa_1 r_1) = \sum_{C=J,Y} c_C C_{\kappa_1 r_1}(\kappa_1 r)\]

where \(C\) indexes the Bessel functions \(J\) and \(Y\), and

\[(7.15) \quad \kappa_1 = a_0 \sqrt{\frac{k_T}{k_D}}\]

The constants \(c_J\) and \(c_Y\) will be determined later. From the pressure, we determine the derivative according to (see equation 9.1.30 in [1])

\[(7.16) \quad C'_\nu(z) = C_{\nu-1}(z) - \nu z^{-1} C_\nu(z)\]

thus the radial component of flux is given by

\[(7.17) \quad q^D = -k_D \kappa_1 \sum_{C=J,Y} c_C \left(C_{\kappa_1 r_1}(\kappa_1 r) - \frac{r_1}{r} C_{\kappa_1 r_1}(\kappa_1 r)\right)\]

**Solution S3:** For \(r_1 < r \leq r_2\): By equation (7.4)

\[(7.18) \quad \frac{d}{dr} \left(r \frac{dp^D}{dr}\right) = 0,\]

the solution of which is the logarithm, and since \(k_T(r) = 0\) for \(r > r_1\), we know that the total flux around any perimeter enclosing \(r_1\) is given by \(q^N\). This determines the constant for the logarithmic term, and we obtain:

\[(7.19) \quad p^D(r) - p^D(r_1) = -\frac{q^N}{2\pi k_D} \ln \left(\frac{r}{r_1}\right)\]
The radial component of flux is given by

\[ q_r^D = \frac{q^N}{2\pi} \frac{1}{r} \]

**Solution S4**: For \( r_2 < r \leq r_3 \): By equation (7.4)

\[ \frac{1}{r} \frac{d}{dr} \left( r \frac{dp^D}{dr} \right) = -\frac{r^D}{kb}(r - r_2)(r_3 - r), \]

the solution of which is a fourth-order polynomial plus a logarithmic term.

\[ p^D(r) - p^D(r_2) = c_4 \ln \left( \frac{r}{r_2} \right) + \frac{r^D}{kD} \left( \frac{r^4 - r_2^4}{16} - (r_3 + r_2) \frac{r^3 - r_3^3}{9} + r_2 r_3 \frac{r^2 - r_2^2}{4} \right) \]

The radial component of flux is given by

\[ q_r^D = -k^D \frac{c_4}{r} - \frac{r^D}{r_0^D} \left( \frac{r^3}{4} - (r_3 + r_2) \frac{r^2}{3} + r_2 r_3 \frac{r}{2} \right) \]

However, since the outer boundary condition of \( \Omega \) is zero Neumann, and we have continuity of flux with respect to the solution S4 at \( r_3 \), this implies that we can determine the constant multiplier of the logarithmic term by setting \( q_r^D(r_3) = 0 \), which yields:

\[ c_4 = \frac{r_0^D}{kD} \left( \frac{r_3^4}{12} - \frac{r_2 r_3^3}{6} \right) \]

**Solution S5**: For \( r_3 < r \): By equation (7.4)

\[ \frac{d}{dr} \left( r \frac{dp^D}{dr} \right) = 0, \]

the solution of which is again the logarithm as in S3. However, in accordance with the zero Neumann boundary condition, the flux is zero, and all that remains is a constant.

\[ p^D(r) - p^D(r_3) = 0 \]

and

\[ q_r^D = 0 \]

**Constants.** It remains to determine the constants \( c_I, c_J \) and \( c_Y \) from solutions S1 and S2. The solutions S1 and S2 must satisfy three criteria: 1) The pressure must be continuous at \( r_0 \), 2) the flux must be continuous at \( r_0 \), and 3) The flux must be continuous at \( r_1 \). This leads to three linear constraints on the constants.

These criteria can be made precise using the solutions derived above as follows.

2) **Pressure continuity** Continuity of pressure at \( r_0 \) requires that

\[ c_I I_0(\kappa_0 r_0) = \sum_{c=I,Y} c_c C_{\kappa_1 r_1}(\kappa_1 r_0) \]
3) Flux continuity at $r_0$. Continuity of flux at $r_0$ requires that

\begin{equation}
(7.29) \quad c_I \kappa_0 I_1(\kappa_0 r_0) = \kappa_1 \sum_{C=I,Y} c_C \left( C_{\kappa, r_1} - 1(\kappa_1 r_0) - \frac{\kappa_1 r_1}{\kappa_1 r_0} C_{\kappa, r_1} (\kappa_1 r_0) \right)
\end{equation}

3) Flux continuity at $r_1$. Continuity of flux at $r_0$ requires that

\begin{equation}
(7.30) \quad \frac{q^N}{2\pi r_1} = -kD \kappa_1 \sum_{C=I,Y} c_C \left( C_{\kappa, r_1} - 1(\kappa_1 r_1) - C_{\kappa, r_1} (\kappa_1 r_1) \right)
\end{equation}

The three equations (7.30), (7.28) and (7.29) provide the three linear constraints for the unknown constants.

For the special case where $r_0 = r_1$, two of the constants, $c_I$ and $c_Y$ are superfluous, and the remaining constant is obtained by combining equations (7.28) and (7.29) as:

\begin{equation}
(7.31) \quad c_I kD \kappa_0 I_1(\kappa_0 r_1) = -\frac{q^N}{2\pi r_1}
\end{equation}
