Abstract

This paper shows that in general, difference fields do not have a difference closure. However, we introduce a stronger notion of closure (κ-closure), and show that every algebraically closed difference field $K$ of characteristic 0, with fixed field satisfying a certain natural condition, has a κ-closure, and this closure is unique up to isomorphism over $K$.

Introduction

In this paper, a difference field is a field $K$ with a distinguished automorphism $σ$. A difference field $L$ is difference-closed if every finite system of difference equations with coefficients in $L$ which has a solution in a difference field extending $L$, already has a solution in $L$.

If $K$ is a difference field, then a difference-closure of $K$ is a difference-closed field containing $K$, and which $K$-embeds into every difference-closed field containing $K$.

The algebra of difference fields was developed by Ritt, in analogy with the algebra of differential fields. It is well-known that any differential field of characteristic 0 has a differential closure, and that this differential closure is unique up to isomorphism over the field. In 2016, Michael Singer asked whether this result generalises to the context of difference fields. One of the main results of this paper is that it does not, even after imposing some natural conditions on the difference field $K$. We will show by two examples (1.3 and 1.4) that even the existence of a difference closure can fail.

There are several natural strengthenings of the notions of difference-closed and difference-closure (originating from model-theory but which have a natural algebraic translation), and we will show that these notions do satisfy existence and uniqueness of closure, provided we work over an algebraically closed difference field of characteristic 0 whose fixed subfield is large enough.

The theory of difference-closed difference fields has been extensively studied, and is commonly

denoted by ACFA. The proof of our result uses in an essential way the characteristic 0 hypothesis, as it allows us to use techniques of stability theory. They provide examples of structures which are stable over a predicate, see [12] and [14] for definitions. The main result of the paper is

**Theorem 3.14.** Let $\kappa$ be an uncountable cardinal or $\aleph_\epsilon$, and let $K$ be an algebraically closed difference field of characteristic 0 such that $F := \text{Fix}(\sigma)(K)$ is pseudo-finite and is $\kappa$-saturated. Then there is a $\kappa$-prime model of ACFA over $K$. Furthermore, it is unique up to isomorphism over $K$.

Here is an algebraic translation of this result for $\kappa \geq \aleph_1$: Call a difference field $U$ $\kappa$-closed if every system of $< \kappa$ difference equations over $U$ which has a solution in some difference field extending $U$, has a solution in $U$. The field $U$ is a $\kappa$-closure of the difference field $K$ if it is $\kappa$-closed, contains $K$, and $K$-embeds into every $\kappa$-closed difference field containing $K$. Then Theorem 3.14 states, for $\kappa \geq \aleph_1$:

Let $K$ be an algebraically closed difference field of characteristic 0, whose fixed field $F$ is pseudo-finite and such that every system of $< \kappa$ polynomial equations over $F$ which has a solution in a regular extension of $F$, already has a solution in $F$. Then $K$ has a $\kappa$-closure, and it is unique up to $K$-isomorphism.

It is unlikely that this result can be generalised to the characteristic $p$ context, and in fact, I conjecture that unless the difference field $K$ of characteristic $p > 0$ is of cardinality $< \kappa$ or is already $\kappa$-closed, then it does not have a $\kappa$-closure.

The paper is organised as follows. In section 1 we discuss the problem and reformulate it in model-theoretic terms, and describe the two examples. In section 2, we state the preliminary results we will need from difference algebra and model theory. Section 3 contains the proof of Theorem 3.14.

1. **Discussion of the problems and the examples**

1.1. **Notation and conventions.** All difference fields will be inversive, i.e., the endomorphism $\sigma$ will be onto. Let $K$ be a difference field, contained in some large difference field $U$. If $a$ is a tuple in $U$, we denote by $K(a)_\sigma$ the difference field generated by $a$ over $K$, i.e., the subfield $K(\sigma^i(a))_{i \in \mathbb{Z}}$ of $U$. The algebraic and separable closure of a field $L$ are denoted by $L^{alg}$ and $L^s$ respectively, and $G(K)$ denotes the absolute Galois group of $K$, i.e., $\text{Gal}(K^s/K)$. If $A \subset U$, then $\text{acl}(A)$ denotes the smallest algebraically closed difference field containing $A$; it coincides with the model-theoretic algebraic closure of $A$ for the theory ACFA (1.7 in [5]). We denote by $\mathcal{L}$ the language $\{+, -, \cdot, 0, 1, \sigma\}$.

1.2. **Translation into model-theoretic terms.** Let $K$ be a difference field. Recall that any complete theory extending the theory ACFA of difference-closed difference fields is supersimple, unstable, of SU-rank $\omega$, and does not eliminate quantifiers, but it eliminates imaginaries. It is extensively studied in [5]. The reason ACFA does not eliminate quantifiers is that given
an automorphism $\sigma$ of a field $K$, there may be several non-isomorphic ways of extending $\sigma$ to $K^{\text{alg}}$. So, the first obvious obstacle to the existence of a difference closure is that, and a natural condition to impose is to assume that $K$ is algebraically closed. There is another natural condition one needs to impose: if $L$ is difference closed, then its fixed field $\text{Fix}(\sigma)(L) = \{ a \in L \mid \sigma(a) = a \}$ is pseudo-finite. Moreover, every pseudo-finite field can occur as the fixed field of some difference closed field ([1]). Thus if $L$ is the difference-closure of a difference field $K$, then $\text{Fix}(\sigma)(L)$ must be prime over $\text{Fix}(\sigma)(K)$ (for its theory in the language of rings). Duret showed in [8] that any completion of the theory of pseudo-finite fields has the independence property. From his proof one extracts easily the fact that non-algebraic types are non-isolated, and this forces us to require in case $K$ is countable that $\text{Fix}(\sigma)(K)$ be pseudo-finite in order to hope to have a difference closure. The case when $K$ is uncountable is a little more complicated, the question is addressed and solved in [3].

It is therefore reasonable to make the following two assumptions:

$K$ is algebraically closed, and $\text{Fix}(\sigma)(K)$ is pseudo-finite.

But even this is not enough. To show this does not suffice, what we need to do is the following:

$\text{Exhibit a difference field } K \text{ satisfying the above two conditions, and a finite system of difference equations which does not have a solution in } K, \text{ and such that any finite strengthening of this system has several completions.}$

This looks easy, since even our stable types are only superstable, not $\omega$-stable. However, the first obvious examples . . . do not satisfy the first condition. Here is a more involved example, taken from [5] (example 6.7):

**Example 1.3.** An example in characteristic 0.

Let $k$ be a countable pseudo-finite field of characteristic 0 containing $\mathbb{Q}^{\text{alg}}$, and consider $K = (k^{\text{alg}}, \sigma)$, where $\sigma$ is a (topological) generator of $\text{Gal}(K/k)$. We consider the elliptic curve $J_a$, with $j$-invariant $a \notin K$, and which is defined by

$$y^2 + xy = x^3 - \frac{36}{a - 1728} x - \frac{1}{a - 1728}.$$  

We let $A'$ be a cyclic subgroup of $J_a$ of order $p^2$, $A = [p]A'$ and $a_1$ the $j$-invariant of the elliptic curve $J_a/A$, $a_2$ the $j$-invariant of the elliptic curve $J_a/A'$. Then the map $\mathbb{Q}^{\text{alg}}(a, a_1) \to \mathbb{Q}^{\text{alg}}(a_1, a_2)$ which is the identity on $\mathbb{Q}^{\text{alg}}$ and sends $(a, a_1)$ to $(a_1, a_2)$ extends to a field automorphism of $\mathbb{Q}(a)^{\text{alg}}$, which in turns extends to an automorphism of $K(a)^{\text{alg}}$ which agrees with $\sigma$ on $K$. Let $\Phi(x, x_1, x_2)$ be the finite system of polynomial equations which describe the algebraic locus of $(a, a_1, a_2)$ over $K$; in the notation of Chapter 5 §3 of [13] (see in particular Theorem 5), $\Phi(x, x_1, x_2)$ can be written as

$$\Phi_{p^2}(x_2, x) = \Phi_p(x_1, x) = \Phi_p(x_2, x_1) = 0.$$  

(The equation $\Phi_n(y, x) = 0$ says that $y$ is the $j$-invariant of the quotient of the elliptic curve $J_x$ with $j$-invariant $x$ by a cyclic subgroup of order $n$.) We now consider the formula $\psi(x)$ given
by \(\Phi(x, \sigma(x), \sigma^2(x)) \land \sigma(x) \neq x\). Let \(b\) be any solution of \(\psi(x)\). Note that necessarily, the kernel of the map \(J_b \to J_{\sigma^n(b)}\) for \(n > 0\) is cyclic of order \(p^n\). Indeed, note that \(\sigma^n(b)\) will satisfy \(\psi\) for every \(n\); hence, the kernel of the map \(J_{\sigma^n(b)} \to J_{\sigma^{n+2}(b)}\) is cyclic of order \(p^2\), and this map is the composite of the two maps \(J_{\sigma^n(b)} \to J_{\sigma^{n+1}(b)}\) and \(J_{\sigma^{n+1}(b)} \to J_{\sigma^{n+2}(b)}\), which both have kernel of order \(p\). An easy induction then gives the result.

As \(\sigma(b) \neq b\), we know that \(b\) is transcendental. Hence the curve \(J_b\) is not of CM-type, its endomorphism group is isomorphic to \(\mathbb{Z}\), and therefore \(J_b\) is not isomorphic to any of its quotients by finite cyclic subgroups (see e.g. section C.11 in [15]). Therefore, the elements \(b, \sigma(b), \sigma^2(b), \ldots\) are all distinct, and \(b \not\in K\). Furthermore the isomorphism type of \(K(b)_\sigma\) over \(K\) is determined by \(\Phi(b, \sigma(b), \sigma^2(b))\), because as we saw above, the kernel of the map \(J_b \to J_{\sigma^n(b)}\) is cyclic of order \(p^n\) for \(n > 0\) (see also the discussion at the bottom of page 3058 in [5]).

So any difference-closed field containing \(K\) must contain a solution of \(\psi(x)\). However, Example 6.7 of [5] shows that if \(b\) is as above, and \(L\) is any finite extension of \(K(b)_\sigma\), then there are \(2^{2^{\aleph_0}}\) non-isomorphic ways of extending \(\sigma\) to \(L_{\text{alg}}\). Thus \(K\) does not have a difference closure.

One can build other examples along the same lines, using moduli spaces of abelian varieties.

**Example 1.4.** An example in characteristic \(p > 0\).

Let \(K = k(A)_{\sigma\text{alg}}\), where \(k\) is a countable pseudo-finite field fixed by \(\sigma\), \(\sigma\) restricts to a generator of \(\text{Gal}(k_{\text{alg}}/k)\), and \(A\) is the set of solutions of the equation \(\sigma(x)^p - \sigma(x) + x^p = 0\) (in some countable difference-closed overfield). Then in any difference-closed field containing \(K\), the set \(B\) of solutions of the equation \(\sigma(x) - x^p + x = 0\) will be an infinite-dimensional \(\mathbb{F}_p\)-vector space. However, as was shown in example 6.5 of [5], there are \(2^{|A|}\) ways of extending \(\sigma\) from \(Kk(B)_{\sigma\text{alg}}\) to \(K(B)_{\sigma\text{alg}}\); there is a definable non-degenerate bilinear map \(q : A \times B \to \mathbb{F}_p\), which can be chosen totally arbitrarily.

In fact this example is part of a large family of examples: let \(f\) and \(g\) be additive polynomials with coefficients in a difference field \(K\), and assume that the subgroup \(A\) of \(\mathbb{G}_a\) defined by \(f(x) = g(\sigma(x))\) is locally modular. Then there is a definable subgroup \(B\) of \(\mathbb{G}_a\), and a definable non-degenerate bilinear map \(A \times B \to \mathbb{F}_p\). As above, there is no prime model over \(K(A)_{\sigma}\).

While we provided examples of difference fields not having a difference closure, we did not provide a procedure which, given a difference field which is not difference closed, exhibits a non-isolated type which needs to be realised. So, the following remains open:

**Question 1.5.** Are there any difference fields which are not difference closed but admit a difference closure?

Omar León Sánchez and Marcus Tressl introduced in [11] the notion of large differential fields of characteristic 0, and they showed that their (field-theoretic) algebraic closure are differentially closed, thus showing that the theory DCF\(_0\) can have minimal prime models. One may try introduce the notion of large difference field, and hope for a similar result.
2 Preliminaries

Basic difference algebra.

2.1. Let $K \subset \mathcal{U}$ be difference fields. If $X = (X_1, \ldots, X_n)$, the ring $K[X]_\sigma = K[\sigma^i(X_j)]_{1 \leq j \leq n, i \in \mathbb{N}}$ is called the $n$-fold difference polynomial ring. A difference equation is an equation of the form $f(X) = 0$ for some $f(X) \in K[X]_\sigma$.

If $a$ is a finite tuple in $\mathcal{U}$, and $L$ is a difference subfield of $K(a)_\sigma$ containing $K$, then $L = K(b)_\sigma$ for some finite tuple $b$ (5.23.18 in [7]).

An element $a \in \mathcal{U}$ is transformally algebraic over $K$ if it satisfies some non-trivial difference equation with parameters in $K$. Otherwise, it is transformally transcendental over $K$. A tuple $a$ is transformally algebraic over $K$ if all its elements are. A (maybe infinite) tuple of elements of $\mathcal{U}$ is transformally independent over $K$ if it does not satisfy any non-trivial difference equation with coefficients in $K$. A transformal transcendence basis of $\mathcal{U}$ over $K$ is a subset $B$ of $\mathcal{U}$ which is transformally independent over $K$ and maximal such; every element of $K$ will then be transformally algebraic over $K(B)_\sigma$. We denote by $\Delta(K)$ the transformal transcendence degree of $K$, i.e., the cardinality of a transformal transcendence basis of $K$, and if $L$ is difference field containing $K$, by $\Delta(L/K)$ the cardinality of a transformal transcendence basis of $L$ over $K$.

2.2. The fixed field. The fixed field of $\mathcal{U}$ is the field $\text{Fix}(\sigma)(\mathcal{U}) := \{a \in \mathcal{U} \mid \sigma(a) = a\}$. Then $\text{Fix}(\sigma)(\mathcal{U})$ and $K$ are linearly disjoint over their intersection. (Choose $n$ minimal such that there are $c_1, c_2, \ldots, c_n \in \text{Fix}(\sigma)$ and $d_1 = 1, d_2, \ldots, d_n \in K$ such that $\sum_i c_i d_i = 0$; applying $\sigma$ we get $\sum c_i \sigma(d_i) = 0$, and by minimality of $n$, that $\sigma(d_i) = d_i$ for all $i$.) This implies in particular that if $E$ is a difference subfield of $K$, then $E \text{Fix}(\sigma)(\mathcal{U})$ and $K$ are linearly disjoint over their intersection $E(\text{Fix}(\sigma)(\mathcal{U}) \cap K)$. In positive characteristic, similar results hold for the other fixed fields $\text{Fix}(\sigma^m \text{Frob}^m)$.

Basic model-theoretic facts.

2.3. For references see [5]. The theory ACFA is supersimple, of SU-rank $\omega$. It eliminates imaginaries, but does not eliminate quantifiers. The completions of ACFA are given by describing the isomorphism type of the automorphism $\sigma$ of the algebraic closure of the prime field (1.4 in [5]).

We let $\mathcal{U}$ be a sufficiently saturated model of ACFA, and $K$ a difference subfield of $\mathcal{U}$.

2.4. Types, algebraic closure, independence. If $a$ is a tuple of elements of $\mathcal{U}$, then $tp(a/K)$ is determined by the isomorphism type of the difference field $\text{acl}(Ka) = K(a)_\sigma^{alg}$ over $K$: $a$ and $b$ have the same type over $K$ if and only if there is a $K$-isomorphism of difference fields $K(a)_\sigma \to K(b)_\sigma$ which send $a$ to $b$ and extends to the algebraic closure of $K(a)_\sigma$ (1.5 in [5]). The SU-rank of $a$ over $K$, denoted by $SU(a/K)$, is bounded by tr.deg$(K(a)_\sigma/K)$, and is finite if and only if tr.deg$(K(a)_\sigma/K)$ is finite (if and only if $a$ is transformally algebraic over $K$).

Let $A, B, C$ be subsets of $\mathcal{U}$. Then $A$ is independent from $B$ over $C$, denoted $A \perp_C B$, if and only
if the fields acl(AC) and acl(BC) are free over acl(C). Equivalently, if whenever a is a tuple of elements in A, then the prime σ-ideal \( I_\sigma(a/\text{acl}(C)) := \{ f(X) \in \text{acl}(BC)[X]| f(a) = 0 \} \) is generated (as a σ-ideal) by its intersection with acl(C)[X]. Then independence coincides with non-forking, and we will also say, in that case, that \( tp(A/BC) \) does not fork over C.

2.5. Reducts. Let \( n > 0 \) be an integer. We denote by \( \mathcal{L}[n] \) the language \( \{+,-,\cdot,0,1,\sigma^n\} \), and by \( \mathcal{U}[n] \) the reduct \( (\mathcal{U},\sigma^n) \) to the language \( \mathcal{L}[n] \). By Corollary 1.12 of [5], \( \mathcal{U}[n] \models \text{ACFA} \). If a is a tuple in \( \mathcal{U} \), then \( tp(a/K)[n] \) denotes the type of \( a \) in the reduct \( \mathcal{U}[n] \), and \( qftp(a/K)[n] \) the quantifier-free type of \( a \) in the reduct \( \mathcal{U}[n] \).

2.6. Notions of canonical bases. If a is a tuple in \( \mathcal{U} \), then \( \text{Cb}(a/K) \) denotes the smallest difference field over which \( I_\sigma(a/K) \) is defined. Then \( tp(a/K) \) does not fork over \( \text{Cb}(a/K) \). Also, \( \text{Cb}(a/K) \) is contained in the algebraic closure over \( K \) of finitely many independent realisations of \( tp(a/K) \); if \( K(a)_\sigma \) is a regular extension of \( K \), then \( \text{Cb}(a/K) \) is contained in the difference field generated over \( K \) by finitely many independent realisations of \( tp(a/K) \) (see the proof of Lemma 2.13(4) in [5]). \( \text{Cb}(a/K) \) will denote \( \text{Cb}(a/K)^{alg} \). Note that a (finitary) type does not fork over some finite set.

2.7. The generic type. The generic 1-type is the type of a transformally transcendental element. It is axiomatised by its quantifier-free part, is definable and stationary\(^1\). Similarly, if \( V \) is a variety defined over the algebraically closed difference field \( K \), then the generic type of \( V \) (which is characterised by having a realisation \( a \) with \( \Delta(K(a)_\sigma/K) = \dim(V) \)) is axiomatised by its quantifier-free part, is definable and stationary (see 2.11 in [5]).

2.8. Orthogonality of types. Let \( p \) and \( q \) be (partial) types over \( A \) and \( B \) respectively.

If \( A = B \), we say that \( p \) and \( q \) are almost orthogonal (or weakly orthogonal), denoted by \( p \perp^a q \), if whenever \( a \) realises \( p \) and \( b \) realises \( q \), then \( a \perp_A b \).

We say that \( p \) and \( q \) are orthogonal, denoted by \( p \perp q \), if whenever \( C \) contains \( A \cup B \), and \( a \) realises \( p \), \( b \) realises \( q \), and \( a \perp_A C \), \( b \perp_{B} C \), then \( a \perp_C b \).

2.9. The dichotomy in characteristic 0. Recall that a partial type \( \pi \) over a set \( A \) is called one-based\(^2\) if whenever \( a_1,\ldots,a_n \) realise \( \pi \) and \( B \supset A \), then \( (a_1\ldots a_n) \perp_C B \), where \( C = \text{acl}(Aa_1,\ldots,a_n) \cap \text{acl}(B) \).

Types of finite SU-rank are analysable in terms of types of SU-rank 1. The main result of [5] says that in characteristic 0, a type \( q \) of SU-rank 1 is either one-based, or non-orthogonal to the fixed field. Moreover, if \( q \) is one-based, then it is stable stably embedded, and definable. See Theorem 4.10 in [5].

2.10. Stable embeddability of the fixed field. Recall that a subset \( S \) of \( \mathcal{U}^m \), which is definable or ∞-definable, is stably embedded if whenever \( D \subset \mathcal{U}^m \) is definable with parameters from \( \mathcal{U} \), then \( D \cap S^m \) is definable with parameters from \( S \). An important result of [5]
(Proposition 1.11) says that the fixed field $F := \text{Fix}(\sigma)$ of $U$ is stably embedded: if $D \subset F^n$ is definable in the difference field $U$ (with parameters from $U$), then it is definable in the pure field language in $F$ (with parameters from $F$). In fact, one has more: let $C = \text{acl}(C) \subset U$, and $a$ a tuple in $F$; then $\text{tp}_F(b/C \cap F) \vdash \text{tp}_F(b/C)$: indeed, all finite $\sigma$-stable extensions of $CF$ are contained in $CF_{\text{alg}}$ (see Lemma 4.2 in [4]), and therefore any $(C \cap F)$-automorphism of the field $F$ extends to a $C$-automorphism of the difference field $\text{acl}(CF)$, since it obviously extends to a $C$-automorphism of $CF$, and the automorphism $\sigma$ of $CF_{\text{alg}}$ extends uniquely to $\text{acl}(CF)$ up to isomorphism over $CF_{\text{alg}}$ (Babbitt’s Theorem. See e.g. Lemma 2.8 in [5]).

For more properties of stably embedded sets or types, see the appendix of [5].

2.11. More on stable stably embedded types. For a definition of a (partial) type being stable stably embedded, see Lemma 2 of the appendix of [5]. Here we will use the following consequence: let $A = \text{acl}(A)$ be algebraically closed, and suppose that $\text{tp}(a/A)$ is stable stably embedded. Then $\text{tp}(a/A)$ is definable (over $A$; see Lemma 1 in the Appendix of [5]). Also, if $B = \overline{\text{TB}}(a/A)$ and $\text{tp}(a/B) \perp^a \text{tp}(a/B)$, then $\text{tp}(a/B) \vdash \text{tp}(a/A)$: this is because $\text{tp}(a/B)$ has a unique non-forking extension to any superset of the algebraically closed set $B$.

**Definition 2.12. (Internality to the fixed field).** Let $\pi$ be a partial type over $A \subset U$, and $F = \text{Fix}(\sigma)(U)$.

1. $\pi$ is qf-internal to $\text{Fix}(\sigma)$ if there is some finitely generated over $A$ difference field $C$ such that whenever $a$ realises $\pi$, there is a tuple $b$ in $F$ such that $a \in C(b)$. I.e., $a \in CF$.

2. $\pi$ is almost-internal to $\text{Fix}(\sigma)$ if there is some some finitely generated over $A$ difference field $C$ such that whenever $a$ realises $\pi$, there is a tuple $b$ in $F$ such that $a \in \text{acl}(Cb)$.

**Remarks 2.13.** Clearly qf-internality implies almost-internality. Moreover, to show qf-internality or almost-internality of a (complete) type $p$, it is enough to do it for a particular realisation $a$ of the type $p$, i.e., to find $C$ independent from $a$ over $A$ such that $a \in CF$ or $a \in \text{acl}(CF)$. See Lemma 5.2 in [5].

Internality or almost internality (to $\text{Fix}(\sigma)$) of a type is in fact a property of its quantifier-free part.

Recall that a difference field $E$ is linearly disjoint from $F$ over $F \cap E$. It follows that in (1) above, the tuple $b$ can be taken so that $C(b) = C(a)_\sigma$: take a generating tuple $d$ of the (pure) field extension $F \cap C(a)_\sigma$ of $F \cap C$; as $F$ is linearly disjoint from $C(a)_\sigma$ over $F \cap C(a)_\sigma$, we get that $CF$ is linearly disjoint from $C(a)_\sigma$ over $C(d)$, i.e., that $C(a)_\sigma = C(d)$ since $a \in CF$.

**Lemma 2.14.** Let $A = \text{acl}(A)$, and assume that $\text{tp}(a/A)$ is almost internal to $\text{Fix}(\sigma)$. Then there is $a' \in A(a)_\sigma$ such that $\text{tp}(a'/A)$ is qf-internal to $\text{Fix}(\sigma)$, $\sigma(a') \in A(a')$, and $a \in \text{acl}(AA')$.

**Proof.** By assumption there is some tuple $c$ independent from $a$ over $A$ and such that $a \in \text{acl}(AFc)$. Taking $b$ in $F$ such that $A(c,a)_\sigma \cap F = (F \cap A)(b)$, we obtain that $F$ is linearly disjoint from $A(c,a)_\sigma$ over $(F \cap A)(b)$, and therefore that $AF(c,b)_\sigma$ and $A(c,a)_\sigma$ are linearly disjoint over $A(c,b)_\sigma$, so that $a \in \text{acl}(Acb)$ (since $a \in \text{acl}(AFcb)$). As $c$ is independent from $a$ over $A = \text{acl}(A)$, it follows that $A(c,a)_\sigma = A(c,a,b)_\sigma$ is a regular extension of $A(a)_\sigma$, and
therefore that \( Cb(b,c/A(a)_\sigma) \) is contained in the difference field generated by finitely many independent realisations of \( tp(b,c/A(a)_\sigma) \) (see 2.6). Again, as \( c \) is independent from \( a \) over \( A \) and \( b \) is in \( F \), it follows that if \( a' \) is such that \( Cb(c,b/A(a)_\sigma) = A(a')_\sigma \), then \( tp(a'/A) \) is qf-internal to \( \text{Fix}(\sigma) \). As \( b \in A(a',c)_\sigma \) and \( c \) is independent from \( a \) over \( A \), it follows that \( a \in \text{acl}(Aa') \) as desired. As \( A(c,a')_\sigma = A(c,b)_\sigma \) and \( b \in F \), it follows that \( A(c,a')_\sigma \) is finitely generated as a field extension of \( A(c)_\sigma \). But as \( a' \) and \( c \) are independent over \( A \), the same holds of the field extension \( A(a')_\sigma/A \), i.e., for some \( n \), \( \sigma^n(a') \in A(a',\sigma(a')\ldots,\sigma^{n-1}(a')) \). We then replace \( a' \) by \((a',\sigma(a')\ldots,\sigma^{n-1}(a'))\).

2.15. The semi-minimal analysis. Let \( a \) be a tuple which is transformally algebraic over \( K \). Thus \( SU(a/K) < \omega \). As \( \text{Th}(U) \) is supersimple, there is a sequence \( a_1,\ldots,a_n \in \text{acl}(Ka) \), such that \( a \in \text{acl}(Ka_1,\ldots,a_n) \), and for every \( 0 < i \leq n \), \( tp(a_i/\text{acl}(K,a_1,\ldots,a_{i-1})) \) is either one-based of rank 1, or almost-internal to a non-one-based type of rank 1. This is a classical result in supersimple theories, for a proof in our case in characteristic 0, see Theorem 5.5 in [5]. Note that in characteristic 0 by the above dichotomy 2.9, all non-one-based types of rank 1 are non-orthogonal to \( \sigma(x) = x \), and by Lemma 2.14, almost-internality to \( \text{Fix}(\sigma) \) may be replaced by qf-internality to \( \text{Fix}(\sigma) \).

**Definition 2.16.** Let \( T \) be a completion of \( \text{ACFA} \), \( M \) a model of \( T \).

1. We say that \( M \) is \( \aleph_\epsilon \)-**saturated** if whenever \( A \subseteq M \) is finite, then every strong 1-type over \( A \) is realised in \( M \). Equivalently, as our theory eliminates imaginaries, if every 1-type over \( \text{acl}(A) \) is realised in \( M \).

2. Let \( \kappa \) be an infinite cardinal or \( \aleph_\epsilon \), and \( A \subseteq M \). We say that \( M \) is \( \kappa \)-**prime over \( A \)**, if \( M \) is \( \kappa \)-saturated, and \( A \)-embeds elementarily into every \( \kappa \)-saturated model of \( \text{Th}(M,a)_{a \in A} \). When \( \kappa = \aleph_\epsilon \), one also says that \( M \) is \( \kappa \)-**prime over \( A \)**.

3. Let \( \kappa \) be an infinite cardinal or \( \aleph_\epsilon \). We say that \( A \subseteq M \) is **small** if \( A = \text{acl}(A_0) \), where \( A_0 \) is finite if we are dealing with \( \aleph_\epsilon \)-saturation, and has cardinality \( < \kappa \) if we are dealing with \( \kappa \)-saturation. We will also say that \( A \subseteq M \) is **very small** if \( A = \text{acl}(A_0) \), where \( A_0 \) is finite. Note that a (very) small set is in particular algebraically closed.

4. Let \( \kappa \) be an infinite cardinal or \( \aleph_\epsilon \), and \( A \subseteq M \). A type \( p \) over \( A \) is \( \kappa \)-**isolated** if it is implied by its restriction to some small subset of \( \text{acl}(A) \).

5. We say that \( M \) is \( \kappa \)-**atomic over \( A \subseteq M \) if whenever \( a \) is a (finite) tuple in \( M \), then \( tp(a/A) \) is \( \kappa \)-isolated. Recall also that \( M \) is **atomic over \( A \)** if every finite tuple realises an isolated type over \( A \).

6. We say that \( B = \text{acl}(B) \subseteq M \) is \( \kappa \)-**constructed over \( A \subseteq M \) if there is a sequence \( (d_\alpha)_{\alpha < \mu} \) in \( B \setminus A \) such that for every \( \alpha < \mu \), \( tp(d_\alpha/\text{acl}(Ad_\beta \mid \beta < \alpha)) \) is \( \kappa \)-isolated and \( B = \text{acl}(Ad_\alpha \mid \alpha < \mu) \).
Remarks 2.17.  (1) If \( \kappa \) is a regular cardinal, then \( \kappa \)-atomicity is transitive: if \( A \subseteq B \subseteq C \subseteq M \), with \( B \) \( \kappa \)-atomic over \( A \) and \( C \) \( \kappa \)-atomic over \( B \), then \( C \) is \( \kappa \)-atomic over \( A \). This is however not necessarily true when \( \kappa \) is singular. However, this will hold if \( B = acl(Ab) \) for some finite tuple \( b \) (since every finite tuple in \( B \) realises an isolated type over \( Ab \), or if \( C \) is atomic over \( B \). (There are stronger statements involving cardinals \( \lambda < \text{cf}(\kappa) \).)

(2) If \( M \) is a \( \kappa \)-saturated model of \( T \) containing \( A \) and \( M \) is \( \kappa \)-constructed over \( A \), then \( M \) is \( \kappa \)-prime over \( A \).

(3) The property of being \( \kappa \)-constructed is preserved under towers and union of chains indexed by ordinals.

2.18. Algebraic translation of the model-theoretic notions

Let us translate what the notions of saturation mean in our case. We will be dealing with either uncountable cardinals or \( \aleph \varepsilon \). Recall that \( tp(a/A) \) is entirely determined by the isomorphism type over the difference field generated by \( A \) of the difference field \( acl(Aa) \) (2.4). So, for \( \kappa \) an uncountable cardinal, the \( \kappa \)-saturation of a model \( M \) of ACFA simply means: every system of \( < \kappa \) difference equations with coefficients in \( M \), which has a solution in a difference field extending \( M \), already has a solution in \( M \). This is what was called \( \kappa \)-closed in the introduction. The notion of \( \kappa \)-prime over a difference subfield corresponds to being a \( \kappa \)-closure of that difference field.

In the case of \( \aleph \varepsilon \)-saturation, the algebraic description is a little more complicated, and is better expressed in terms of embedding problems: work inside a large model \( U \), and consider a submodel \( M \) of \( U \). Then \( M \) is \( \aleph \varepsilon \)-saturated if whenever \( a \) is a finite tuple of elements of \( M \) and \( b \) an element of \( U \), there is an acl\((a)\)-embedding of acl\((a, b)\) inside \( M \).

A similar description holds for \( \kappa \)-saturated, with the base set \( a \) of cardinality \( < \kappa \): a model \( M \) of ACFA is \( \kappa \) saturated if whenever \( A \subset M \) is small and \( b \) is a finite tuple in some difference field \( U \) containing \( M \), then there is an \( A \)-embedding of acl\((Ab)\) into \( M \). Note that \(|A|\)-many difference equations are necessary to describe the isomorphism type of acl\((Ab)\) over \( A \).

3 The results

Results of Hrushovski ([10]) show that if \( F \) is a pseudo-finite field and \( C \subset F \), then Th\((F, c)_{c \in C}\) eliminates imaginaries if and only if the absolute Galois group of the relative algebraic closure inside \( F \) of the field generated by \( C \) is isomorphic to \( \hat{\mathbb{Z}} \). It may therefore happen that Th\((F)\) eliminates imaginaries in the ring language, but it may also happen that extra elements are needed, for instance if \( F \) contains \( \mathbb{Q}_{\text{alg}} \). The following lemma will therefore be useful when dealing with \( \aleph \varepsilon \)-saturation.

Lemma 3.1. Let \( F \) be an \( \aleph \varepsilon \)-saturated pseudo-finite field and \( a \) a finite tuple in \( F \). Then there is a finitely generated subfield \( A \) of \( F \) containing \( a \) and such that \( G(A_{\text{alg}} \cap F) \simeq \hat{\mathbb{Z}} \).

Proof. Let \( k \) be the relative algebraic closure inside \( F \) of the subfield generated by \( a \), and consider \( k(t) \), where \( t \) is transcendental over \( k \). Let \( Q_0 \) be the set consisting of all integers \( n \)
which are either prime numbers or 4 and such that $G(k)$ does not have a quotient isomorphic to $\mathbb{Z}/n\mathbb{Z}$. If $\text{char}(k) \neq 0$, we let $Q = Q_0 \setminus \{4\}$, and if $\text{char}(k) = 0$, we let $Q = Q_0 \setminus \{2\}$. If $Q$ is empty, then $G(k) \simeq \hat{\mathbb{Z}}$, and we are done. So, we assume that $Q$ is non-empty.

By Proposition 16.3.5 of [9], for each $n$, $k(t)$ has a Galois extension $L_n$ which is regular over $k$ and with $\text{Gal}(L_n/k(t)) = \mathbb{Z}/n\mathbb{Z}$. Let $L$ be the field composite of all $L_n$, $n \in Q$. Then $\text{Gal}(L/k(t)) \simeq \prod_{n \in Q} \mathbb{Z}/n\mathbb{Z}$. Observe that $L \cap k^{\text{alg}} = k$, because all $L_n$'s are regular extensions of $k$, and Galois over $k(t)$ of relatively prime order.

Take a topological generator $\sigma_0$ of $\text{Gal}(L/k(t))$, and a topological generator $\sigma_1$ of $G(k)$. Let $\sigma \in G(k(t))$ extend $\langle \sigma_0, \sigma_1 \rangle \in \text{Gal}(L^{\text{alg}}/k(t)) \simeq \text{Gal}(L/k(t)) \times G(k)$; then the subfield $A$ of $k(t)^{\text{alg}}$ fixed by $\sigma$ is a regular extension of $k$, with Galois group isomorphic to $\hat{\mathbb{Z}}$, since its Galois group is procyclic, projects onto $G(k)$, onto all $\mathbb{Z}/p\mathbb{Z}$ with $p$ a prime, and onto $\mathbb{Z}/4\mathbb{Z}$ if $\text{char}(k) = 0$.

By general properties of pseudo-finite fields and by $\aleph_0$-saturation of $F$, there is a $k$-embedding $\varphi$ of $A$ inside $F$, in such a way that $\varphi(A)^{\text{alg}} \cap F = \varphi(A)$. This is classical, and follows for instance from Lemma 20.2.2 in [9].

**Lemma 3.2.** Let $\kappa$ be an uncountable cardinal or $\aleph_0$, let $K$ be a difference field, with $\text{Fix}(\sigma)(K)$ pseudo-finite and $\kappa$-saturated. Then there is a model $U$ of ACFA containing $K$, which is $\kappa$-saturated, and with $\text{Fix}(\sigma)(U) = \text{Fix}(\sigma)(K)$.

**Proof.** (Compare with Afsheidol’s result [1].) Let $U_1$ be a $\kappa$-saturated model of ACFA containing $K$, and let $U \subseteq U_1$ be maximal such that $U := \text{Fix}(\sigma)(U) = \text{Fix}(\sigma)(K)$. We will show that $U$ satisfies our conclusion. First observe that $U$ is algebraically closed. Let $A = \text{acl}(A) \subset U$ be small, let $p \in S_1(A)$. Then $p$ is realised in $U_1$, and we take some $a \in U_1$ realising $p$, with $\text{SU}(a/U)$ minimal. Let $B \supset A$ be small and such that $a \perp B\mathcal{U}$ and replace $p$ by $tp(a/B)$.

If $tp(a/U) \perp^a \text{Fix}(\sigma)$, then $U(a)^{\text{alg}}$ has the same fixed field as $U$: indeed, $U(a)^{\text{alg}}$ and $\text{Fix}(\sigma)(U_1)$ are linearly disjoint over their intersection, which is contained in $U$ and therefore in $K$. So by maximality of $U$, $a \in U$.

Assume now that $tp(a/U) \not\perp^a \text{Fix}(\sigma)$. Then there is some small $C \subset U$ containing $B$, and a realisation $a'$ of $tp(a/B)$ such that $C(a') \cap \text{Fix}(\sigma)(U_1)$ contains some element $b$ not in $U$. We may and will assume that $\text{Fix}(\sigma)(C)$ has absolute Galois group isomorphic to $\hat{\mathbb{Z}}$ (by Lemma 3.1). But as $F$ is $\kappa$-saturated, $tp_F(b/C \cap F)$ is realised in $F$, and some $b_1$. Then $b_1$ realises $tp(b/C)$ (see the first paragraph of 2.10). Thus, by $\kappa$-saturation of $U_1$, there is some $a_1 \in U_1$ such that $tp(a_1, b_1/C) = tp(a', b/C)$. But then $a_1$ realises $p$, and $\text{SU}(a_1/U) \leq \text{SU}(a'/B) - \text{SU}(b/C) < \text{SU}(a/B)$, which gives us the desired contradiction.

So in both cases, $p$ is realised in $U$.

**Corollary 3.3.** Let $\kappa$ be as above, and $K$ an algebraically closed difference field with $\text{Fix}(\sigma)(K)$ $\kappa$-saturated. If $U$ is a $\kappa$-prime model of ACFA over $K$ then $\text{Fix}(\sigma)(U) = \text{Fix}(\sigma)(K)$.

**Lemma 3.4.** Let $U$ be an $\aleph_0$-saturated model of ACFA of characteristic 0, and let $K$ be an algebraically closed difference subfield of $U$ which contains $F := \text{Fix}(\sigma)(U)$. Let $a \in U$ be such that $p = tp(a/K)$ is $\text{gf}$-internal to $\text{Fix}(\sigma)$, $p \perp^a \text{Fix}(\sigma)$, and assume that $\sigma(a) \in K(a)$. Then there are $a$ (very) small $A \subseteq K$ and a tuple $b \in U$ of realisations of $p$ such that:
(1) $FA(b)$ contains all realisations (in $U$) of $qftp(a/A)[\ell]$, for any $\ell \geq 1$.

(2) If $b' \in U$ realises $qftp(b/A)[m]$ for some $m \geq 1$, then $FA(b')$ contains all realisations (in $U$) of $qftp(a/A)[\ell]$ for $\ell \geq 1$.

(3) $tp(a/A) \vdash tp(a/K)$, and $tp(b/A) \vdash tp(b/K)$.

Proof. Let $k \subset K$ be small such that $a \bot k$ and $Gal(\text{Fix}(\sigma)(k)^{alg}/\text{Fix}(\sigma)(k))$ is isomorphic to $\hat{Z}$. Then $\sigma(a) \in k(a)$ and $kF$ contains $\text{Fix}(\sigma^\ell)(U)$ for all $\ell \geq 1$. By assumption, there is some small $B$ (in $U$, by $\aleph_n$-saturation of $U$) independent from $a$ over $k$, such that $a \in BF$. Hence, there is a tuple $c$ in $B(a)_\sigma \cap F = B(a) \cap F$ such that $B(a) = B(c)$ (by 2.13). Let $D = Cb(a,c/B)$. Then $D(c) = D(a)$, and $D \subset k(c_1,a_1,\ldots,c_n,a_n)$ for some independent realisations $(c_i,a_i)$ of $qftp(c,a/B)$ (in some elementary extension of $U$). By $\aleph_n$-saturation of $U$, we may assume that $(c_1,a_1,\ldots,c_n,a_n)$ is in $U$, and is independent from $(c,a)$ over $D$. We let $b = (a_1,\ldots,a_n)$, $A = Cb(k,c_1,a_1,\ldots,c_n,a_n)/K$; then $D \subset kF(b)$, and $A$ is small. As $A$ contains $c_1,\ldots,c_n$ (in $F \subset K$) and $k$, we also have $D \subset A(b)$, whence $a \in FA(b)$. Note that $a \bot k$ since $A \subset K$.

If $a' \in U$ realises $qftp(a/A(b))$, then the difference fields $D(a)$ and $D(a')$ are isomorphic; hence there is some $c' \in D(a') \cap F$ such that $D(c') = D(a')$, i.e.: $a' \in FA(b)$.

Let $a'$ be an arbitrary realisation of $qftp(a/A)$, and let $b'$ be a realisation of $qftp(b/A)$, which is independent from $(b,a')$ over $A$. By the previous paragraph (as $b'$ consists of $n$ realisations of $qftp(a/A(b))$) we know that $b' \in FA(b)$. The difference fields $A(b)$ and $A(b')$ are $A$-isomorphic, and this isomorphism extends to an isomorphism of difference fields $A(b,a) \rightarrow A(b',a')$. Hence, $a' \in FA(b') \subseteq FA(b)$, as desired. If $a'$ realises $qftp(a/A)[\ell]$ and is independent from $D$ over $k$, then the $\sigma^\ell$-difference fields $D(a')$ and $D(a)$ are isomorphic over $D$. Let $f(x)$ be the tuple of rational functions over $D$ such that $f(a) = c$; then $\sigma^\ell(f(a')) = f(a')$ and $D(a') = D(f(a'))$. Hence $a'$ belongs to $FA(b)$. An argument similar to the one given in the first case shows it for arbitrary realisation of $qftp(a/A)[\ell]$ and shows (1).

Note that we have in fact shown that $FA(b') = FA(b)$, and so the conclusion of (1) also holds for $b'$. An easy argument allows to remove the assumption that $b'$ is independent from $b$ over $A$: let $b''$ realise $qftp(b/A)$, independent from $(b,b')$ over $A$; then by the proof of the first part: $FA(b'') = FA(b)$ and $FA(b') = FA(b'')$.

Working in $U[\ell]$, and noting that if $m$ divides $\ell$, then the realisations of $qftp(a/A)[m]$ also realise $qftp(a/A)[\ell]$, part (1) gives (2).

For the proof of (3), we will first show that every realisation $b'$ of $qftp(b/A)[\ell]$ (in $U$) is independent from $K$ over $A$. Indeed, by (2), we know that $FA(b) = FA(b')$, and therefore $FK(b) = FK(b') = K(b) = K(b')$ (as $A,F \subseteq K$). This implies that tr.deg$(b/K) = \text{tr.deg}(b'/K)$, and therefore that $b' \bot K$. As $U$ is $\aleph_n$-saturated and $A$ is small, this shows that if $d \in K$, then $qftp(b/A)[\ell] \perp^a qftp(d/A)[\ell]$.

By Proposition 4.9 of [5], if $tp(b/A) \not\vdash tp(b/K)$, then there would be some tuple $d \in K$ and
integer $\ell \geq 1$ such that $qftp(d/A)[\ell] \nsubseteq tp(b/A)[\ell]$. But as we just saw, this is impossible, and this gives us (3). (This is where the characteristic 0 assumption is crucial).

**Remark 3.5.** In the above notation, note that if $U \prec U'$ and $F' = \text{Fix}(\sigma(U'))$, then $F'A(b)$ contains all realisations of $qftp(a/A)[\ell]$ in $U'$, for any $\ell \geq 1$.

**Lemma 3.6.** Let $K, A, b, U$ be as in Lemma 3.4, and let $L$ be a difference subfield of $U$ containing $K$. Then there is a small $A'$ containing $A$ such that $tp(b/A') \vdash tp(b/L)$. In particular, $tp(a/A') \vdash tp(a/L)$.

**Proof.** Let $A' \subset L$ be small, containing $A$ and such that $b \not\in A'L$. Then the proof of (3) works.

**Corollary 3.7.** Let $K$ and $U$ be as in Lemma 3.4, and $p$ be a type which is almost internal to $\text{Fix}(\sigma)$. Then any $K$-indiscernible sequence $(a_i)$ of realisations of $p$ in $U$ is finite.

**Proof.** Let $(a_i)_{i<\omega}$ be a sequence of realisations of $p$ in $U$ which is $K$-indiscernible. Then either $a_0 \in K$, or $tp(a_0/K)$ is almost orthogonal to $\text{Fix}(\sigma)$ (since $K$ contains $F := \text{Fix}(\sigma)(U)$). By Lemma 2.14 there is $a'_0 \in K(a_0)$ such that $\sigma(a'_0) \in K(a'_0)$, $a_0 \in K(a'_0)^{alg}$ and $tp(a'_0/K)$ is $qf$-internal to $\text{Fix}(\sigma)$. It suffices to show the result for $p = tp(a'_0/K)$. Let $b$ be the finite tuple of realisations of $tp(a'_0/K)$ given by Lemma 3.4. If $n > d = \text{tr.deg}(K(b)/K)$ and $tp(a'_i, a_i/K) = tp(a'_0, a_0/K)$, then we know that $a'_n \in K(a'_0, \ldots, a_{d-1})^{alg}$ (because $K \supset F$). Hence the sequence is finite.

**Definition 3.8.** We call a type $p$ over a set $A$ acceptable (in $K \supset A$) if $A$ is the algebraic closure of a finite tuple, and either $\text{SU}(p) = 1$ and $p$ is one-based, or $p$ is $qf$-internal to $\text{Fix}(\sigma)$, almost orthogonal to $\text{Fix}(\sigma)$, and if $b$ realises $p$ then $\sigma(b) \in A(b)$, $tp(b/A) \vdash tp(b/K)$, and the set of realisations of $qftp(b/A)[\ell]$ for $\ell \geq 1$, in some model $U$ of ACFA containing $K$, is contained in $A(b)\text{Fix}(\sigma)(U)$.

**Notation 3.9.** Let $p$ be a one-based type of SU-rank 1 over the very small set $A$. If $A \subset B \subset C$, we denote by $p|B$ the unique non-forking extension of $p$ to $B$, and by $\text{dim}_{BP}(C)$ the cardinality of a maximal $B$-independent subset of realisations of $p|B$ in $C$.

**Lemma 3.10.** Let $p$ be an acceptable one-based type over the very small $A$, let $K$ be an algebraically closed difference field containing $A$. We work in a sufficiently saturated model $U$ of ACFA. Let $\kappa$ be an uncountable cardinal or $\aleph_1$.

1. If $K$ contains $\kappa$ many $A$-independent realisations of $p$, then the non-forking extension of $p$ to $K$ is not $\kappa$-isolated, and conversely.

2. Assume that $\text{dim}_A p(K) < \kappa$. One of the following holds:

   (a) There is some $n < \omega$ and realisations $a_0, \ldots, a_{n-1}$ of $p|K$ such that $\text{dim}_A p(acl(Ka_0, \ldots, a_{n-1})) \geq \kappa > \text{dim}_A p(K)$. Moreover, if $n$ is minimal with this property, then $tp(a_0, \ldots, a_{n-1}/K)$ is $\kappa$-isolated (but $p|acl(Ka_0, \ldots, a_{n-1})$ is not).
By Lemma 3.4, there is a finite tuple \( b \). Assume now that \( \forall \sigma \exists b/Ca\sigma \) or almost-internal to \( \text{Fix}(\sigma) \). The result is obvious. The proof is by induction on \( \text{SU}(\kappa) \).

(2) (a) is clear by (1) and because \( \text{dim} \) is additive. So, assume that there is no such \( n \), and let \( B \) be as in (b), and \( (a_i)_{i < \lambda} \subset B \) a sequence of independent over \( K \) realisations of \( p \), and assume that \( \lambda < \dim_A p(\text{acl}(KB)) = \mu \geq \kappa \). So \( \text{acl}(K, a_i \mid i < \lambda) \) contains a set \( C \) consisting of \( \mu \) many \( A \)-independent realisations of \( p \). Then for each \( c \in C \), there is some finite \( I_c \subset \lambda \) such that \( c \in \text{acl}(Ka_i \mid i \in I_c) \). As \( \lambda < \mu \), some set \( I_c \) appears \( \mu \) times. Thus \( \dim_A p(\text{acl}(Ka_i \mid i \in I_c)) = \mu \geq \kappa \), which contradicts our assumption.

**Remark 3.11.** Let \( p \) be the generic 1-type over \( K \), and \( \kappa \) an infinite cardinal. Then \( p \) is \( \kappa \)-isolated if and only if \( \Delta(K) < \kappa \). This follows easily from the description and properties of the generic types, see 2.7.

**Definition 3.12.** Let \( K = \text{acl}(K) \subset L = \text{acl}(L) \subset U \). We say that \( L \) is normal over \( K \) (in \( U \)) is whenever \( a \) is a tuple in \( L \), then \( L \) contains all realisations of \( tp(a/K) \) in \( U \).

**Lemma 3.13.** Let \( \kappa \) be an uncountable cardinal or \( \aleph_\varepsilon \), let \( K \subseteq L \) be algebraically closed difference subfields of \( U \), where \( U \) is \( \kappa \)-saturated, and \( \text{Fix}(\sigma)(U) \subset K \). Assume that \( U \) is \( \kappa \)-atomic over \( K \).

1. Let \( a \) be a finite tuple in \( U \). Then \( U \) is \( \kappa \)-atomic over \( a/Ka \).

2. Let \( B \subset U \) be transformally independent over \( K \), and assume that either \( |B| < \kappa \), or that \( B \) is an transformal transcendence basis of \( U \) over \( K \). Then \( U \) is \( \kappa \)-atomic over \( acl(KB) \).

3. If \( L \) is normal over \( K \) then \( U \) is \( \kappa \)-atomic over \( L \).

**Proof.** (1) Clearly \( U \) is \( \kappa \)-atomic over \( Ka \), but we want something stronger. Let \( b \in U \) be a finite tuple, and let \( C \) be a small subset of \( K \) such that \( tp(a, b/C) \vdash tp(a, b/K) \). Note that if \( b' \) realises \( tp(b/Ca) \) then \( b' \downarrow_{Ca} K \) since \( (a, b') \downarrow_{C} K \) by \( \kappa \)-isolation of \( tp(a, b/K) \).

Let us first show the result when \( \text{SU}(b/Ca) < \omega \). If \( \text{SU}(b/Ca) = 0 \), then \( b \in \text{acl}(Ca) \) and the result is obvious. The proof is by induction on \( \text{SU}(b/Ca) \); using the semi-minimal analysis of \( tp(b/acl(Ca)) \) and induction, we may assume that \( tp(b/acl(Ca)) \) is either 1-based of \( \text{SU}(b/Ca) \), or almost-internal to \( \text{Fix}(\sigma) \). If \( tp(b/acl(Ca)) \) is one-based, then it is also stable, hence has a unique non-forking extension to any superset of \( acl(Ca) \), in particular to \( acl(Ka) \), and by the remark in the previous paragraph, we get the result: \( tp(b/acl(Ca)) \vdash tp(b/acl(Ka)) \).

Assume now that \( tp(b/acl(Ca)) \) is almost-internal to \( \text{Fix}(\sigma) \), and let \( b' \in acl(Cab') \) be such that \( b \in acl(Cab') \), \( \sigma(b') \in acl(Ca)(b') \), and \( tp(b'/acl(Ca)) \) is qf-internal to \( \text{Fix}(\sigma) \) (see Lemma 2.14). By Lemma 3.4, there is a finite tuple \( e \in acl(Ka) \) such that \( tp(b'/acl(e)) \vdash tp(b'/acl(Ka)) \). Then
**tp(b'/acl(Ca)) ⊢ tp(b'/acl(Ka)), and because b ∈ acl(Cab'), we get the desired conclusion.**

For the general case: because b is a finite tuple, there is a finite tuple d ∈ acl(Cab) such that SU(d/Ca) < ω, and tp(b/acl(Cad)) is orthogonal to all types of finite SU-rank. (Indeed, this follows from supersimplicity: if tp(b/acl(Ca)) is non-orthogonal to some type q of finite SU-rank, there is b₁ ∈ acl(Cab) with 0 < SU(b₁/acl(Ca)) < ω; repeat the procedure with tp(b/acl(Cab₁)) until it stops.) By the first case, we know that there is a small C' ⊂ acl(Ka) containing C such that tp(d/acl(C'a)) ⊢ tp(d/acl(Ka)), and that acl(Kad) is κ-atomic over acl(Ka). By Remark 2.17(1), it suffices to show that tp(b/acl(Kad)) is κ-isolated. By Theorem 5.3 in [6] (see also Appendix B, loc. cit.), tp(b/acl(Cad)) is stationary. But by the first paragraph of the proof, we know that every realisation of tp(b/acl(Cad)) will be independent from K over acl(Cad), and this gives the result.

(2) If B = ∅ there is nothing to prove, so suppose it is not. Then ∆(K) < κ by 3.11. Let a be a finite tuple in U, and let b ⊂ B be a finite tuple such that a ⊑ₖ B. Let c be a transformational transcendence basis of K(a,b) over K(b) (and therefore also over K(B)). If c ≠ ∅, then |B| < κ, ∆(K(B)) < κ, and therefore tp(c/acl(KB)) is κ-isolated. Moreover, as a is transformally algebraic over K(b,c), and B \ {b} is purely transformally transcendental over K(b,c), tp(a/acl(Kbc)) and tp(B/acl(Kbc)) are orthogonal, and by stationarity of tp(B/acl(Kbc)), we get that tp(B/acl(Kbc)) ⊢ tp(B/acl(Kba)). By symmetry,

\[ tp(a/acl(Kbc)) ⊢ tp(a/acl(KBa)). \]

But tp(a,b,c/K) is κ-isolated, hence so is tp(a/acl(Kbc)) by (1), and this gives the result.

(3) Let a be a finite tuple in U, and consider tp(a/L). Let d ⊂ a be maximal transformally independent over L. If d ≠ ∅, then d is transformally independent over K, which implies that ∆(L/K) = 0 (by normality of L/K), and that ∆(K) = ∆(L) < κ (by κ-isolation of tp(d/K)). Therefore tp(d/L) is κ-isolated.

If ∆(L/K) ≠ 0, note that by normality of L over K in U, every element of the tuple a which is not in L is transformally algebraic over K. So, replacing a by a \ L, we may assume they are all transformally algebraic over K, i.e., that SU(a/K) < ω. We then let d = ∅.

In both cases, by (2), U is κ-atomic over acl(Kd), and the normality of L over K implies the normality of acl(Ld) over acl(Kd). Working over acl(Kd), we may therefore assume that a and D := acl(a/L) are transformally algebraic over K.

We use induction on SU(a/L), and using the semi-minimal analysis, we find b ∈ acl(Da) such that tp(a/acl(Db)) is either one-based of SU-rank 1, or almost-internal to Fix(σ).

If tp(a/acl(Db)) is almost-internal to Fix(σ), then so is tp(a/acl(Lb)). By Lemma 2.14, there is a' ∈ acl(Lba) such that a ∈ acl(Lba') and tp(a'/acl(Lb)) is qf-internal to Fix(σ). By Lemma 3.4, there is a very small D' ⊇ D such that tp(a'/acl(Db)) ⊢ tp(a'/acl(Lb)), and we may choose it so that a ∈ acl(D'ba'). This shows that tp(a/acl(Lb)) is κ-isolated, and therefore so is tp(a/L).

So assume that p := tp(a/acl(Db)) is one-based of SU-rank 1, and let c be a tuple containing b such that acl(Db) = acl(c) := C. We need to show that dim_C p(acl(Lc)) < κ. As U is κ-atomic over K, we know that tp(a,c/K) is κ-isolated, and therefore dim_C p(acl(Kc)) < κ. So, if dim_C p(acl(Lc)) ≥ κ, then there is some a' ∈ acl(Lc) \ acl(Kc) realising p. Recall that by
our earlier step, $c,d'$ are transformally algebraic over $K$, and therefore so is $e = \text{Cb}(Kca'/L)$. Consider now $\text{acl}(Kca') \cap \text{acl}(Ke) =: E \subset L$; by Proposition 3.1 of [2], $tp(e/E)$ is almost-
internal to $\text{Fix}(\sigma)$, and therefore orthogonal to all one-based types. As $tp(a'/Kc)$ is one-based, and $a' \in \text{acl}(Ke) \setminus \text{acl}(Kc)$, it follows that $e \in E$, since almost-internality to $\text{Fix}(\sigma)$ and non-orthogonality to a one-based type imply algebraicity. That is, $e \in \text{acl}(Kca') \cap L$, and as $a' \notin \text{acl}(Kc)$, the tuples $a'$ and $e$ are equi-algebraic over $\text{acl}(Kc)$. Hence $\text{acl}(Kca)$ contains a realisation of $tp(e/\text{acl}(Kc))$, because $tp(a/\text{acl}(Kc)) = tp(a'/\text{acl}(Kc))$. But this contradicts the normality of $\text{acl}(Lc)$ over $\text{acl}(Kc)$. So, $\dim_{C}(p(\text{acl}(Lc)) < \kappa$, and $tp(a/Lb)$ is $\kappa$-isolated.

**Theorem 3.14.** Let $\kappa$ be an uncountable cardinal or $\aleph_{\varepsilon}$, and let $K$ be an algebraically closed difference field of characteristic 0 such that $F := \text{Fix}(\sigma)(K)$ is pseudo-finite and is $\kappa$-saturated.

1. Then there is a $\kappa$-prime model $\mathcal{U}$ over $K$.

2. Furthermore, $\mathcal{U}$ is $\kappa$-atomic over $K$, and every sequence of $K$-indiscernibles has length $\leq \kappa$ (i.e., if $\kappa = \aleph_{\varepsilon} \leq \aleph_{0}$; by convention, if $\kappa$ is meant as a cardinal, then $\aleph_{\varepsilon}$ will mean $\aleph_{0}$).

**Proof.** By Lemma 3.2, there is a $\kappa$-saturated model $\mathcal{U}_{1}$ of ACFA containing $K$ and with fixed field $F = \text{Fix}(\sigma)(K)$. We will construct a submodel $\mathcal{U}$ of $\mathcal{U}_{1}$, which is $\kappa$-prime over $K$ and satisfies (2). This $\mathcal{U}$ will be $\kappa$-constructed.

**Step 0.** Taking care of the transformal transcendence degree. If the transformal transcendence degree of $K$ is $< \kappa$, then as any $\kappa$-saturated model of ACFA has transformal transcendence degree at least $\kappa$, we enlarge $K$ as follows: let $B \subseteq \mathcal{U}_{1}$ be a set which is transformally independent over $K$ and of cardinality $\kappa$; by 2.11 of [5], this condition completely determines the $K$-isomorphism type of $K(B)_{alg}$, and therefore any $\kappa$-prime model will contain a $K$-isomorphic copy of $K(B)_{alg}$. We let $K_{0} = K(B)_{alg}$. We need to show (2). Each finite subset of $B$ realises a $\kappa$-isolated type over $K$, since the transformal transcendence degree of $K$ is $< \kappa$. Moreover, every tuple in $K_{0}$ realises an isolated type over $K(B)_{\sigma}$; hence $K_{0}$ is $\kappa$-atomic over $K$. It is also $\kappa$-constructed over $K$.

Let $(a_{i})_{i<\lambda} \subseteq K_{0}$ be a $K$-indiscernible sequence, $\lambda$ a cardinal. If the $a_{i}$’s are transformally independent over $K$, then we know that $|\lambda| \leq \kappa$. If not, then by indiscernibility, the transformal transcendence degree of $K(a_{i} \mid i < \lambda)_{\sigma}$ over $K$ is finite, and we choose a finite subset $c$ of $B$ such that $K(a_{i} \mid i < \lambda)_{\sigma}$ is transformally algebraic over $K(c)_{\sigma}$. As the elements of $B$ are transformally independent over $K$, this implies that all $a_{i}$’s are in fact algebraic over $K(c)_{\sigma}$. Consider now $D := \text{alg}(c/Ka_{i} \mid i < \lambda)$. For every $i$, we know that $a_{i} \in D(c)_{\sigma}^{alg}$, and therefore by definition of $D$, $a_{i} \in D(c)_{\sigma}^{alg}$. But $c$ is finite, $D$ is contained in the algebraic closure of a finite set (by 2.6), and therefore $D(c)_{\sigma}^{alg}$ is countable. Hence so is $\lambda$. This shows condition (2) for the extension $K_{0}/K$.

We will build a sequence $K_{n}$, $n < \omega$, of algebraically closed difference subfields of $\mathcal{U}_{1}$, such that:

1. if $p$ is an acceptable type over a very small $A \subseteq K_{n}$, then $K_{n+1}$ contains $\kappa$-many $A$-independent realisations of $p$;
2. $K_{n+1}$ is $\kappa$-constructed over $K_{n}$.
We let $K_0 = K$ if the transformal transcendence degree of $K$ is $\geq \kappa$, and $K(B)^{alg}$ as in step 0 otherwise. We assume $K_n$ constructed, we wish to build $K_{n+1}$. Let $p_\beta$, $\beta < \lambda$, be an enumeration of the acceptable types in $K_n$, with corresponding very small bases $A_\beta$.

**Step 1.** Defining $K_{n+1} = \bigcup_{\beta < \lambda} K'_\beta$

We build the sequence $K'_\beta$ by induction on $\beta$, and let $K'_0 = K_n$. If $\beta$ is a limit ordinal, then we let $K'_\beta = \bigcup_{\gamma < \beta} K'_\gamma$, and $K_{n+1} = K'_\lambda$. We will build them so that $K'_{\beta+1}$ satisfies the following:

(i') $K'_{\beta+1}$ contains $\kappa$-many $A_\beta$-independent realisations of $p_\beta$;

(ii') $K'_{\beta+1}$ is $\kappa$-constructed over $K'_\beta$.

Assume $K'_\beta$ constructed. If $p_\beta$ has $\kappa$-many $A_\beta$-independent realisations in $K'_\beta$, then we let $K'_{\beta+1} = K'_\beta$. Otherwise, we need to distinguish the two cases:

**Case 1.** $p_\beta$ is one-based.

Let $a_i$, $i < \kappa$, be a sequence of $K'_\beta$-independent realisations of $p_\beta$ (a priori, in some elementary extension of $U_1$). By Lemma 3.10, either there is $n < \omega$ such that $acl(K'_\beta, a_i \mid i < n)$ contains $\kappa$-many $A_\beta$-independent realisations of $p_\beta$; in that case, taking a minimal such $n$, $tp(a_0, \ldots, a_{n-1}/K'_\beta)$ is $\kappa$-isolated and therefore realised in $U_1$, so that we may assume $a_0, \ldots, a_{n-1} \in U_1$ and we set $K'_{\beta+1} = acl(K'_\beta, a_i \mid i < n)$. Then (i') and (ii') follow.

If there is no such $n$, then for every $\lambda < \kappa$, $acl(K'_\beta a_i \mid i < \lambda)$ does not contain $\kappa$-many $A_\beta$-independent realisations of $p_\beta$; by the same reasoning we may assume the $a_i$’s are in $U_1$ and we define $K'_{\beta+1} = acl(Ka_i \mid i < \kappa)$. Then (i’) and (ii’) again are satisfied.

**Case 2.** Not case 1.

Let $a_\beta \in U_1$ realise $p_\beta$, $K'_{\beta+1} = K'_\beta(a_\beta)^{alg}$. By assumption on $p_\beta$, $tp(a_\beta/A_\beta) \models tp(a_\beta/K_n)$. By Lemma 3.6, there is a very small subset $B$ of $K'_\beta$ which contains $A_\beta$ and is such that $tp(a_\beta/B) \models tp(a/K'_\beta)$. So, $tp(a_\beta/K'_\beta)$ is $\kappa$-isolated. We let $K'_{\beta+1} = K'_\beta(a_\beta)^{alg}$. We know that $FK'_\beta(a_\beta)^{alg}$ contains all realisations of $tp(a_\beta/B)$ in $U_1$. But $U_1$ is $\kappa$-saturated, it therefore contains $\kappa$ independent realisations of $tp(a_\beta/A_\beta)$, which shows (i’).

We now define $U = \bigcup_{n<\omega} K_n$.

**Step 2.** Show that $U$ is $\kappa$-saturated.

Let $C \subset U$ be small, and $p$ a 1-type over $C$, realised by $a$ in $U_1$. If $SU(p) = \omega$, then $a$ is transformally transcendental over $C$; as $C$ is small, $K_0$ will contain a realisation of $p$. So we may assume that $SU(p) < \omega$, and the proof is by induction on $SU(p)$: we assume that for any small $D$, any 1-type $q$ over $D$ of smaller SU-rank than $p$ is realised in $U$.

If $SU(p) = 0$ there is nothing to prove, as $p$ is realised in $C$. If there is some $b \in C(a)^{alg}$ such that $0 < SU(b/C) < SU(a/C)$, then we get the result by induction: $tp(b/C)$ is realised by some $b' \in U$, and there is $a' \in U$ such that $tp(a', b'/C) = tp(a, b/C)$, since $acl(Cb')$ is small and $SU(a/Cb) < SU(p)$.

Hence we may assume that there is no such $b$, whence $p$ is either one-based of SU-rank 1, or almost-internal to Fix($\sigma$) (by the semi-minimal analysis 2.15). We need to distinguish three cases.

**Case 1.** $p$ is one-based of SU-rank 1.

Let $A \subset C$ be very small such that $p$ does not fork over $A$. Let $n < \omega$ be such that $A \subset K_n$;
then \( p \), being acceptable, occurs as a \( p_\beta \), and is therefore realised in \( K_{n+1} \).

**Case 2.** \( p \) is realised in \( \text{Fix}(\sigma) \).

If \( a \in \text{Fix}(\sigma) \), we saw in 2.10 that \( tpf(a/C \cap F) \vdash tpf(a/C) \). The saturation hypothesis on \( F \) then gives the result: \( p \) is realised in \( F \).

**Case 3.** Assume now that \( p \perp^a \text{Fix}(\sigma) \), \( p \) almost-internal to \( \text{Fix}(\sigma) \).

By Lemma 2.14, there is \( a_1 \in C(a)_\sigma \) such that \( tp(a_1/C) \) is qf-internal to \( \text{Fix}(\sigma) \), \( \sigma(a_1) \in (c(a_1), a) \), and \( a \in C(a_1)^{\text{alg}} \). We may replace \( p \) by \( tp(a_1/C) \), i.e., assume that \( p \) is qf-internal to \( \text{Fix}(\sigma) \).

Let \( C_0 \subset C \) be very small such that \( p \) does not fork over \( C_0 \). By Lemma 3.4 there is a tuple \( b \) of realisations of \( p \) and a very small \( D \) containing \( C_0 \), contained in \( \text{acl}(CF) \), such that \( FD(b) \) contains all realisations of \( qftp(a/D) \), and \( tp(b/D) \vdash tpf(b/\text{acl}(CF)) \). Thus, \( tp(b/D) \) is acceptable, and if \( n \) is such that \( D \subset K_n \), then \( p \) in realised in \( K_{n+1} \).

**Step 3.** \( U \) is \( \kappa \)-prime over \( K \).

This is clear, by Remarks 2.17(2)(3).

**Step 4.** \( U \) is \( \kappa \)-atomic over \( K \).

When \( \kappa \) is regular or \( \aleph_\text{I} \), then this follows from \( U \) being \( \kappa \)-constructed over \( K \). The proof in the singular case is a little more delicate, and is made by induction. We already saw that \( K_0 \) is \( \kappa \)-atomic over \( K \). Let \( a \) be a finite tuple in \( U \), and (in the notation of Step 1), choose \( n \) minimal such that \( a \in K_{n+1} \), and \( \beta \) minimal such that \( a \in K_{\beta+1} \). If \( n = -1 \), there is nothing to prove (by Step 0), so assume \( n \geq 0 \). By definition of \( K_{\beta+1} \), there are a tuple \( b \) in \( K_{\beta} \) and a tuple \( c \) of realisations of \( p_\beta \) such that \( a \in \text{acl}(Kbc) \). We may assume that \( \text{acl}(Kb) \) contains \( A_\beta \), and that \( c \perp_{Kb} K_{\beta} \).

By induction hypothesis, \( tp(b/K) \) is \( \kappa \)-isolated, and it therefore suffices to show that \( tp(c/\text{acl}(Kb)) \) is \( \kappa \)-isolated (by 2.17(1)). If \( p_\beta \) is qf-internal to \( \text{Fix}(\sigma) \) then we know by Lemma 3.4 that there is some very small \( D \subset \text{acl}(Kb) \) such that \( tp(c/D) \vdash tpf(c/\text{acl}(Kb)) \), and we are done.

If \( p_\beta \) is one-based, then we may assume that the elements of the tuple \( c \) are independent over \( K_{\beta} \), maybe at the cost of increasing \( b \in K_{\beta} \). Then, by the construction of \( K_{\beta+1} \) in Step 1, we know that \( tp(c/K_{\beta}) \) is \( \kappa \)-isolated, so that if \( c' \) is a proper subtuple of \( c \) (consisting of realisations of \( p_\beta \)), then \( \dim_{A_\beta} p_\beta(\text{acl}(K_{\beta}c')) < \kappa \). In particular, \( \dim_{A_\beta} p(\text{acl}(Kbc')) < \kappa \), and \( tp(c/\text{acl}(Kb)) \) is \( \kappa \)-isolated (by Lemma 3.10).

**Remarks.** (Notation as in step 1 and above) The same proof shows that \( U \) is \( \kappa \)-atomic over each \( K_n \), and over each \( K_{\beta} \).

Moreover, the fact that \( U \) is \( \kappa \)-atomic over \( K_{\beta} \) implies that \( p_\beta(U) \subset K_{\beta+1} \).

**Step 5.** If \( (b_i)_{i<\lambda} \subset U \) is \( K \)-indiscernible, with \( \lambda \) a cardinal, then \( \lambda \leq \kappa \).

By supersimplicity, for some \( n < \omega \) the elements \( b_i \), \( n < i < \lambda \), are independent over \( K(b_0, \ldots, b_n)_\sigma \).

If \( \text{SU}(b_{n+1}/Kb_0, \ldots, b_n) \geq \omega \), then the tuple \( b_{n+1} \) contains an element which is transformally transcendental over \( K \), and as the transformal transcendence degree of \( U \) over \( K \) is \( \leq \kappa \), we get \( \lambda \leq \kappa \). So we may assume \( \text{SU}(b_{n+1}/\text{acl}(Kb_0, \ldots, b_n)) < \omega \).

Let \( L = \text{acl}(Kb_0, \ldots, b_n) \). Then the sequence \( (b_i)_{n<i<\lambda} \) is indiscernible over \( L \). Note that the sequence \( \text{acl}(Lb_i) \), \( n < i < \lambda \), is also indiscernible over \( L \) under a suitable enumeration of each \( \text{acl}(Lb_i) \). Hence, if \( c_{n+1} \in \text{acl}(Lb_{n+1}) \), there are \( c_i \in \text{acl}(Lb_i) \), \( n+1 < i < \lambda \), such that the se-
\[\text{Hence, } U \text{ finite).}\]

If \(m > 0\) and \(K_0 \neq K\), let \(B_0\) be a finite subset of \(B\) (the transfinite transcendence basis of \(U\) over \(K\)) such that \(b := (b_0, \ldots, b_n)\) is independent from \(K_0\) over \(acl(KB_0)\). In particular, \(b\) is transformally algebraic over \(acl(KB_0)\), and therefore \(tp(B/\acl(KB_0)) \vdash tp(B/\acl(LB_0))\) (reason as in the proof of Lemma 3.13(1)), and as \(tp(B_0/L)\) is \(\kappa\)-isolated, it follows that \(K_0\) is \(\kappa\)-constructed over \(L\).

Assume now \(m > 0\), and that we have shown that \(LK_\beta\) is \(\kappa\)-constructed over \(L\). If \(p_\beta\) is not one-based, then by Lemma 3.6, \(tp(a_\beta/\acl(LK_\beta))\) is \(\kappa\)-isolated, and we are done. Assume now that \(p_\beta\) is one-based; by construction there is a set \((a_\alpha)_{\alpha < \mu}\) of \(K_\beta\)-independent realisations of \(p_\beta|K_\beta\) such that \(K_\beta^{\alpha+1} = acl(K_\beta, a_\alpha, \alpha < \mu)\), and either \(\mu \in \omega\) or \(\mu = \kappa\).

If \(\mu \in \omega\), as \(U\) is \(\kappa\)-atomic over \(K_\beta\), we get \(tp(a_0, \ldots, a_{\mu-1}, b/K_\beta)\) is \(\kappa\)-isolated and therefore \(LK_\beta^{\alpha+1}\) is \(\kappa\)-constructed over \(LK_\beta^\alpha\). If \(\mu = \kappa\), then \(dim_{K_\beta^{\alpha+1}}(\acl(K_\beta, b, a_\gamma | \gamma < \alpha)|<\kappa\) for each \(\alpha < \kappa\), so that \(LK_\beta^{\alpha+1}\) is \(\kappa\)-constructed over \(LK_\beta^\alpha\) (here we use that \(p_\beta(U) \subset K_\beta^{\alpha+1}\) and that \(b\) is finite).

Hence, \(U\) being \(\kappa\)-prime over \(L\), there is an \(L\)-embedding \(f\) of \(U\) into \(N\). So we have \(L \subset f(U) \subset N < U\). As \(\lambda > \kappa\) and the \(c_i\)'s are independent over \(L\), there is some \(n < j < \lambda\) such that \(f(c_j) \notin M\). But \(dim_M(p) \geq \kappa\), and by Lemma 3.10, \(p|M\) is not isolated. But \(N\) is \(\kappa\)-atomic over \(M\), and \(f(c_j)\) realises \(p\) and is not in \(M\), which gives us the desired contradiction. This finishes the proof of (2) and of the theorem.

**Proposition 3.15.** Let \(\kappa\) be an uncountable cardinal or \(\aleph_c\), let \(U\) and \(U'\) be \(\kappa\)-saturated models of ACFA of characteristic 0. Assume that \(U\) (resp. \(U'\)) contains an algebraically closed difference field \(K\) (resp. \(K'\)), over which it is \(\kappa\)-atomic and over which every sequence of indiscernibles has length \(\leq \kappa\). Assume moreover that \(F := Fix(\sigma)(K) = Fix(\sigma)(U)\), \(Fix(\sigma)(K') = Fix(\sigma)(U')\), and that we have an isomorphism \(f : K \to K'\). Let \(p\) be an acceptable type over some very small \(A \subset K\), and \(p' = f(p)\). If \(L = acl(Kp(U))\) and \(L' = acl(Kp'(U'))\), then \(f\) extends to an isomorphism between \(L\) and \(L'\).

**Proof.** Note that \(p'\) is also acceptable, with very small basis \(A' = f(A)\). If \(p\) is not one-based, then this is clear by Lemma 3.4: \(L = acl(Kb)\), \(L' = acl(K'b')\) for some tuples \(b\) realising \(p\) and \(b'\) realising \(p'\). We extend \(f|A\) to an isomorphism \(g_0 : acl(AB) \to acl(A'B')\) which sends \(b\) to \(b'\); as \(tp(b/A) \vdash tp(b/K)\) and \(tp(b'/A') \vdash tp(b'/K')\), \(g_0 \cup f\) extends to an isomorphism
acl(Kb) → acl(K′b').
Assume now that p is one-based. Any κ-saturated model of ACFA containing A will contain (at least) κ realisations of p which are independent over A; hence so do U and U'. Let \((a_i)_{i<\lambda} \subset U\) be a set of realisations of p which is maximal independent over K, with \(\lambda\) a cardinal, and let \((a'_i)_{i<\mu} \subset U'\) be defined analogously over \(K'\). By Lemma 3.10 and our hypothesis on the length of \(K\)-indiscernible sequences, either \(\lambda\) is finite, or \(\lambda = \kappa\). If \(\lambda = n < \omega\), then as \(\text{tp}(a_0, \ldots, a_{n-1}/K') = f(\text{tp}(a_0, \ldots, a_{n-1}/K))\), it follows that acl\((K'a_0, \ldots, a'_{n-1})\) contains \(\kappa\)-many independent realisations of \(f(p)\), so that \(\mu \leq n\). The symmetric argument gives \(\mu = \lambda\).
Define \(g\) on \(K(a_i \mid i < \lambda)_\sigma\) by \(g(a_i) = a'_i\), and extend to \(L = \text{acl}(Ka_i \mid i < \lambda)\).

**Theorem 3.16.** Let \(\kappa\) be an uncountable cardinal or \(\aleph_\alpha\), let \(U\) and \(U'\) be κ-saturated models of ACFA of characteristic 0 containing an algebraically closed difference field \(K\), with \(F := \text{Fix}(\sigma)(K) = \text{Fix}(\sigma)(U) = \text{Fix}(\sigma)(U')\). Assume that \(U\) and \(U'\) are κ-atomic over \(K\), and that any sequence of \(K\)-indiscernibles in \(U\) or in \(U'\) has length ≤ \(\kappa\). Then \(U \cong_K U'\).

**Proof.** We start with the generic type: if the transensal transcendence degree of \(K\) is \(\geq \kappa\), then \(U\) and \(U'\) are transf maintaining algebraic over \(K\). If not, then let \(D\) be a transensal transcendence basis of \(U\) over \(K\), \(D'\) a transensal transcendence basis of \(U'\) over \(K\). They have the same cardinality \(\kappa\), and there is a \(K\)-isomorphism \(K(D)_{\sigma}^{alg} \rightarrow K(D')_{\sigma}^{alg}\). By Lemma 3.13, \(U\) and \(U'\) still satisfy the hypotheses over \(K(D)_{\sigma}^{alg}\) and \(K(D')_{\sigma}^{alg}\). Hence we may assume that both \(U\) and \(U'\) are transf maintaining algebraic over \(K\). We define by induction on \(n\) an increasing sequence \(K_n\) of algebraically closed subfields of \(U\) such that for each \(n\), if \(p\) is an acceptable type over some (very small) \(A \subset K_{n-1}\), then \(K_n\) contains all realisations of \(p\) in \(U\), and furthermore, \(K_n = \text{acl}(K_{n-1}P)\) for the set \(P\) of all realisations (in \(U\)) of acceptable types over some subset of \(K_{n-1}\). Then each \(K_n\) is normal over \(K_{n-1}\) (and in fact over \(K\)), and so by Lemma 3.13, \(U\) satisfies the hypotheses over \(K_n\). Note also that \(U = \bigcup_{n<\omega} K_n\). We let \(L_n \subset U'\) be defined analogously. It then suffices to build a sequence \(g_n\) of \(K\)-isomorphisms \(K_n \rightarrow L_n\).
Assume \(g_{n-1}\) already built. Let \(p_\beta\), \(\beta < \lambda\), be an enumeration of all acceptable types over a subset of \(K_{n-1}\), with associated small basis \(A_\beta\). Note that \(f(p_\beta)\), \(\beta < \lambda\), enumerates all acceptable types over subsets of \(L_{n-1}\), since if \(q\) is an acceptable type over the very small \(C \subset L_{n-1}\), so is \(g_{n-1}^{-1}(q)\) (over \(g_{n-1}^{-1}(C) \subset K_{n-1}\)). We build by induction on \(\beta < \lambda\) an increasing sequence \(K'_\beta\) of algebraically closed difference subfields of \(U\) such that \(K'_\beta\) contains all realisations in \(U\) of \(p_\gamma\) for all \(\gamma < \beta\). Assume we have extended \(g_{n-1}\) to an isomorphism \(f_\beta : K'_\beta \rightarrow L'_\beta\), where \(L'_\beta\) contains all realisations of \(U'\) of \(g_{n-1}(p_\gamma)\) for all \(\gamma < \beta\). As \(U\) is κ-atomic over \(K_{n-1}\), it is also κ-atomic over \(K'_\beta\) (by Lemma 3.13), and similarly, \(U'\) is κ-atomic over \(L'_\beta = f_\beta(K'_\beta)\). Extending \(f_\beta\) to an isomorphism \(f_{\beta+1} : K'_{\beta+1} \rightarrow L'_{\beta+1}\) is given by Lemma 3.15.
As remarked before, if \(q\) is an acceptable type over some \(A' \subset L'_{n-1}\), then \(g_{n-1}^{-1}(q) = p_\beta\) for some \(\beta < \lambda\), and so \(L'_n\) contains \(q(U')\), and \(K'_n\) contains \(g_{n-1}^{-1}(q)(U)\). This finishes the induction step. Then \(g = \bigcup_{n<\omega} g_n\) is a \(K\)-isomorphism between \(U\) and \(U'\).

**Theorem 3.17.** Let \(\kappa\) be an uncountable cardinal or \(\aleph_\alpha\), let \(K\) be an algebraically closed difference field of characteristic 0, with \(\text{Fix}(\sigma)(K)\) pseudo-finite and κ-saturated. Then ACFA has a κ-prime model over \(K\), and it is unique up to \(K\)-isomorphism.
Proof. This follows immediately from Theorem 3.16 together with Theorem 3.14, as the properties are preserved by elementary substructures.

Remark 3.18. Note that the result also holds under the weaker hypothesis: $K$ algebraically closed, $|\text{Fix}(\sigma)(K)| < \kappa$, and $\kappa^{<\omega} = \kappa \geq \aleph_1$, so that the theory of pseudo-finite fields has a unique (up to $K$-isomorphism) saturated model of cardinality $\kappa$ containing $\text{Fix}(\sigma)(K)$. (This uses the stable embeddability of $\text{Fix}(\sigma)$, see 2.10).
