Summary The reaction of ram seminal vesicle (RSV) microsomes with arachidonic acid (AA) was examined using electron spin resonance (ESR), high performance liquid chromatography-electron spin resonance spectrometry (HPLC-ESR), and high performance liquid chromatography-electron spin resonance-mass spectrometry (HPLC-ESR-MS) combined use of spin trapping technique. A prominent ESR spectrum ($\alpha_N = 1.58 \text{ mT}$ and $\alpha_H = 0.26 \text{ mT}$) was observed in the complete reaction mixture of ram seminal vesicle microsomes with arachidonic acid containing 2.0 mg protein/ml ram seminal vesicle (RSV) microsomal suspension, 0.8 mM arachidonic acid, 0.1 M 4-POBN, and 24 mM tris/HCl buffer (pH 7.4). The ESR spectrum was hardly observed for the complete reaction mixture without the RSV microsomes. The formation of the radical appears to be catalyzed by the microsomal components. In the absence of AA, the intensity of the ESR signal decreased to $16 \pm 15\%$ of the complete reaction mixture, suggesting that the radical is derived from AA. For the complete reaction mixture with boiled microsomes, the intensity of the ESR signal decreased to $49 \pm 4\%$ of the complete reaction mixture. The intensity of the ESR signal of the complete reaction mixture with indomethacin decreased to $74 \pm 20\%$ of the complete reaction mixture, suggesting that cyclooxygenase partly participates in the reaction. A peak was detected on the elution profile of HPLC-ESR analysis of the complete reaction mixture. To determine the structure of the peak, an HPLC-ESR-MS analysis was performed. The HPLC-ESR-MS analysis of the peak showed two prominent ions, m/z 266 and m/z 179, suggesting that the peak is a 4-POBN/pentyl radical adduct. An HPLC-ESR analysis of the authentic 4-POBN/pentyl radical adduct confirmed the identification.

Key Words: radical, arachidonic acid, peroxidation, COX, ESR

Introduction

Cyclooxygenase (COX) catalyzes the primary step in the metabolism of unesterified arachidonic acid to bioactive prostanoids [1, 2]. The prostanoids participate in physiological processes, such as synaptic transmission, neurotransmitter release and cerebral blood flow regulation [3, 4]. The reaction of tissues to certain stresses such as inflammation or injuries is also caused by prostanoids. This metabolic pathway has been shown to play an important role in neurological and neurodegenerative diseases, such as stroke,
epilepsy, and Alzheimer’s disease [3, 4].

The mechanism of prostaglandin synthesis predicts the formation of free radicals derived from the substrate fatty acid [5]. Indeed, Mason et al. observed a characteristic ESR spectrum for the reaction mixture of ram seminal vesicle microsomes with arachidonic acid in the presence of the spin trap, 2-methyl-2-nitrosopropane [6], suggesting that a carbon-centered free radical forms. Substitution of arachidonic acid by octadeuterated (5, 6, 8, 9, 11, 12, 14, 15)-arachidonic acid confirmed that the radical is derived from arachidonic acid. Furthermore, the ESR spectrum showed that the arachidonic acid-derived radical is bound to the spin trap at one of the eight deuterated positions [7].

Free radicals have been successfully detected and identified using ESR spectroscopy combined with spin trapping technique. High performance liquid chromatography-electron spin resonance spectrometry (HPLC-ESR) [8–11] and high performance liquid chromatography-electron spin resonance-mass spectrometry (HPLC-ESR-MS) [12] have also been employed for detection and identification of the radical adducts. To identify the radical formed in the reaction mixture of ram seminal vesicle microsomes with arachidonic acid, the HPLC-ESR and HPLC-ESR-MS were performed. In this paper, pentyl radical is detected and identified in the reaction mixtures of ram seminal vesicle microsomes with arachidonic acid using ESR, HPLC-ESR, and HPLC-ESR-MS combined use of spin trapping technique.

**Materials and Methods**

**Chemicals**

α-(4-Pyridyl-1-oxide)-N-tert-butynitrone (4-POBN), a spin-trapping reagent was purchased from Tokyo Kasei Kogyo, Ltd. (Tokyo, Japan). Arachidonic acid and indomethacin were from Wako Pure Chemical Industries, Ltd. (Osaka, Japan). Pentyldiazirine oxalate was synthesized according to the method of Gever and Hayes [13]. All other chemicals used were of analytical grade.

**Preparation of ram seminal vesicle microsomes**

The ram seminal vesicles (obtained from a local slaughterhouse) were freed of extraneous tissue, cut into small pieces, and homogenized in 0.25 M sucrose (tissue to sucrose ratio of 1:9) using T25 digital ULTRA-TURRAX high-performance disperser (IKA-WERKE GMBH & CO. KG, Staufen, Germany). The homogenate was centrifuged at 12,000 g for 30 min at 4°C. The supernatant fraction was then centrifuged at 120,000 g for 30 min at 4°C. The pellet was suspended in 0.25 M sucrose. Protein concentration of the suspension was 4.8 mg/ml. It was kept at −80°C before use.

The complete reaction mixture of ram seminal vesicle microsomes with arachidonic acid

The complete reaction mixture contained 0.1 M 4-POBN, 2.0 mg protein/ml ram seminal vesicle microsomes and 0.8 mM arachidonic acid in 24 mM tris buffer (pH 7.4). The reaction was started by adding ram seminal vesicle and performed for the ESR, HPLC-ESR, and HPLC-ESR-MS experiments for 60 min at 37°C.

**Preparation of 4-POBN/pentyl radical adduct**

The reaction mixture contained 0.1 M 4-POBN, 4 mg/ml pentyldiazirine oxalate, 0.2 mM CuCl₂ and 45 mM carbonate buffer (pH 10.0) in a total volume of 2 ml. The reaction was started by adding CuCl₂ after bubbling nitrogen gas. It was performed for 120 min under an air atmosphere. In order to purify 4-POBN/pentyl radical adduct, the reaction mixture was applied to the HPLC-ESR.

**ESR measurements**

The ESR spectra were obtained using a model JES-FR30 Free Radical Monitor (JEOL Ltd., Tokyo, Japan). Aqueous samples were aspirated into a Teflon tube centered in a microwave cavity. Operating conditions of the ESR spectrometer were: power, 4 mW; modulation width, 0.1 mT; sweep time, 4 min; sweep width, 10 mT; time constant, 0.3 s. Magnetic fields were calibrated by the splitting of MnO (ΔH₀⁺ = 8.69 mT).

**HPLC-ESR chromatography**

An HPLC used in the HPLC-ESR consisted of a model 7125 injector (Reodyne, Cotari, CA) and a model 655A-11 pump with a model L-5000 LC controller (Hitachi Ltd., Ibaragi, Japan). A semi-preparative column (300 mm long × 10 mm i.d.) packed with TSKgel ODS-120T (TOSOH Co., Tokyo, Japan) was used. Flow rate was 2.0 ml/min throughout the experiments. For the HPLC-ESR, two solvents were used: solvent A, 50 mM acetic acid; solvent B, 50 mM acetic acid/acetonitrile (20:80, v/v). A following combination of isocratic and linear gradient was used: 0–40 min, 100–20% A (linear gradient); 40–60 min, 80% B (isocratic). The eluent was introduced into a model JES-FR30 Free Radical Monitor. The ESR spectrometer was connected to the HPLC with a Teflon tube, which passed through the center of the ESR cavity. The operating conditions of the ESR spectrometer were: power, 4 mW; modulation width, 0.2 mT; time constant, 1 s. The magnetic field was fixed at the third peak in the doublet-triplet ESR spectrum (αβ = 1.58 mT and αββ = 0.26 mT) of the 4-POBN radical adduct.

**HPLC-ESR-MS chromatography**

HPLC and ESR conditions were as described in the HPLC-ESR. The operating conditions of the mass spectrometer were: nebulizer, 180°C; aperture 1, 120°C; N₂
controller pressure, 2.0 kg/cm² drift voltage, 70 V; multiplier voltage, 1800 V; needle voltage, 3000 V; polarity, positive; resolution, 48.

The mass spectra were obtained by introducing the eluent from the ESR detector into the LC-MS system just before the peaks were eluted. The flow rate was kept at 50 μl/min while the eluent was introducing into the mass spectrometer.

Results

ESR measurements of the reaction mixtures of ram seminal vesicle microsomes with arachidonic acid

An ESR spectrum of the complete reaction mixture of ram seminal vesicle microsomes with arachidonic acid was measured (Fig. 1). A prominent ESR spectrum (α_N = 1.58 mT and α_H = 0.26 mT) was observed in the complete reaction mixture (Fig. 1A). The ESR spectrum was hardly observed for the complete reaction mixture without ram seminal vesicle microsomes (Fig. 1B, Table 1). In the absence of arachidonic acid, the intensity of the ESR signal decreased to 16 ± 15% (n = 3) of the complete reaction mixture (Fig. 1C, Table 1). For the complete reaction mixture with boiled microsomes, the ESR signal decreased to 49 ± 4% (n = 3) of the complete reaction mixture (Fig. 1D, Table 1). For the complete reaction mixture with indomethacin, the ESR signal decreased to 74 ± 20% (n = 3) of the complete reaction mixture (Fig. 1E, Table 1).

HPLC-ESR and HPLC-ESR-MS analyses of the reaction mixture of ram seminal vesicle microsomes with arachidonic acid

The HPLC-ESR analyses were performed for the complete reaction mixture of ram seminal vesicle microsomes with arachidonic acid (Fig. 2). A prominent peak was separated on the HPLC-ESR elution profile (Fig. 2A). The retention times of the peak was 49.4 min.

To determine the structure of the peak compound, an HPLC-ESR-MS analysis was performed. The HPLC-ESR-MS analysis of the peak compound gave ions at m/z 266 and m/z 179 (Fig. 3). The ion m/z 266 corresponds to the protonated molecule of 4-POBN/pentyl radical adduct, [M + H]^+ . A fragment ion at m/z 179 corresponds to the loss of (CH_3)C(O)N from the protonated molecules.

In order to confirm the chemical structure of the peak compound, HPLC-ESR analyses were performed for the reaction mixture of pentyldihydrazine with Cu^{2+}. It is well known that penty1 radical forms in the reaction mixture of pentyldihydrazine with Cu^{2+} (11). An HPLC-ESR analysis of the reaction mixture of pentyldihydrazine with Cu^{2+} gave a peak with almost the same retention time as the peak compound (Fig. 2B). When the peak fraction in the reaction mixture of pentyldihydrazine with Cu^{2+} was mixed with the complete reaction mixture of ram seminal vesicle microsomes with arachidonic acid, the peak height of the peak compound increased (Fig. 2C), suggesting that the peak compound and 4-POBN/pentyl radical adduct are identical.

Discussion

In this study, the reaction of ram seminal vesicle microsomes with arachidonic acid was examined using ESR, HPLC-ESR and HPLC-ESR-MS combined use of spin trapping technique. A prominent ESR spectrum (α_N = 1.58 mT and α_H = 0.26 mT) was observed in the complete reaction mixture. The ESR spectrum was hardly observed.
for the complete reaction mixture without ram seminal vesicle microsomes. The ram seminal vesicle microsomes could be essential for the radical formation. The ESR spectrum was hardly observed in the absence of arachidonic acid, suggesting that the radical is derived from arachidonic acid.

HPLC-ESR and HPLC-ESR-MS analyses showed that 4-POBN/pentyl radical adduct forms in a reaction mixture of ram seminal vesicle microsomes with arachidonic acid. A possible reaction path for the formation of the pentyl radical is shown (Scheme 1). The prostaglandin endoperoxide H synthases (PGHSs) exhibit two different but complementary enzymatic activities \([1, 5]\): (i) a COX (bis-oxygenase) which catalyzes the formation of prostaglandin \(\text{G}_2\) (PGG\(_2\)) from arachidonic acid and two molecules of \(\text{O}_2\) and (ii) a peroxidase which facilitates the two-electron reduction of the 15-hydroperoxyl group of \(\text{PGG}_2\). Rota et al. reported the cytochrome-P450-catalyzed one electron reductive homolytic decomposition of \(\text{LOOH}\) \([14]\). The one electron reductive homolytic decomposition of \(\text{LOOH}\) is also catalyzed by the other compounds such as hemoglobin, myoglobin, and cytochrome c \([15–17]\). This reaction yields radical intermediates alkoxyl radical (LO\(^{\prime}\)).

Heme(\(\text{Fe}^{\text{III}}\)) + \(\text{PGG}_2\) \(\rightarrow\) Heme(\(\text{Fe}^{\text{IV}}\)) = \(\text{O} + \text{H}^+ + \text{LO}^{\prime}\), (1)

\(\beta\)-Scission of the \(\text{LO}^{\prime}\) possibly forms the pentyl radical (Scheme 1). Mason et al. observed a characteristic ESR spectrum for the reaction mixture of ram seminal vesicle microsomes with arachidonic acid in the presence of the spin trap, 2-methyl-2-nitroso propane \([6]\), suggesting that a
carbon-centered free radical forms. Substitution of arachidonic acid by octadeuterated (5, 6, 8, 9, 11, 12, 14, 15)-arachidonic acid confirmed that the radical is derived from arachidonic acid. Furthermore, the ESR spectrum showed that the arachidonic acid derived radical is bound to the spin trap at one of the eight octadeuterated positions [7]. The pentyl radicals detected in this paper is obviously different from the one detected by Mason et al. Different spin trap reagents seem to trap different radicals even in a similar reaction.

Recently, 8-isoprostan F12α (PGF12α), a major isoprostane generated through the non-enzymatic peroxidation of arachidonic acid, has been shown to be a reliable indicator of oxidative stresses in various clinical conditions [18]. Reports have shown that F2-isoprostanes are authentic biomarkers of lipid peroxidation and can be used as potential in vivo indicators of oxidant stress, as well as in evaluations of antioxidants or drugs for their free radical-scavenging properties [8]. The PGF12α is formed from PGG2 via prostaglandin endoperoxide H2 (PGH2). The pentyl radical detected in this paper is also form from PGG2. Thus, both pentyl radical and PGF12α are complementary biomarkers of lipid peroxidation.
