Abstract

Purpose Endovascular therapy is widely used in acute large vessel occlusion. This study investigated whether imaging of lateral lenticulostriate arteries (LSAs) before thrombectomy would potentially be helpful for predicting prognosis of patients with acute M1 segment of middle cerebral artery occlusion (MCAO).

Methods 59 consecutive patients with acute M1 segment of MCAO treated with mechanical thrombectomy at two comprehensive stroke center were analyzed. Patients were categorized into LSA+ (appearing of lateral LSAs) and LSA- (sparing of lateral LSAs) group according to preprocedural digital subtraction angiography (DSA). Baseline data and clinical outcomes were compared. A good clinical outcome was defined as a modified Rankin Scale score of 0 to 2 at 3 months. The association between clinical and imaging parameters and functional outcome was evaluated with logistic regression analysis.

Results LSA+ was shown in 36 patients (61%). LSA+ group had a significantly higher proportion of good outcome (72.2% vs. 8.7%, OR 27.3, 95% CI 5.38-138.4, \( P < 0.001 \)), lower risk of symptomatic intracranial haemorrhages (sICH) (8.3% vs. 47.8%, OR 0.10, 95% CI 0.02-0.42, \( P = 0.001 \)) and lower mortality in hospital (5.6% vs. 34.8%, OR 0.11, 95% CI 0.02-0.58, \( P < 0.004 \)) compared with LSA- group. Patients in LSA+ group had lower baseline NIHSS score (\( P < 0.01 \)) and NIHSS score at 14 days (\( P < 0.01 \)) and smaller infarct core volume (\( P = 0.016 \)) on computed tomography perfusion imaging (CTP) compared to the LSA- group. Multivariate logistic regression analysis showed that a small infarct core volume (OR 6.74, 95% CI 1.148-39.569, \( P = 0.035 \)) and LSA+ (OR 22.114, 95% CI 3.339-146.470, \( P = 0.001 \)) were associated with a good clinical outcome.

Conclusions Our data suggest that appearance of lateral LSAs before mechanical thrombectomy would be potentially helpful for predicting favorable prognosis of patients with acute M1 segment of MCAO.
**Background**

Randomized trials have demonstrated that second-generation endovascular thrombectomy had an obvious clinical benefit over medical therapy alone among patients with emergent large artery occlusion (LAO)\(^1\text{-}^5\). However, poor clinical outcomes, despite successful revascularization, are still common\(^6\). Thus, patient selection and prognosis prediction are still key issues for thrombectomy. In addition to the time to treatment, infarct core volume, penumbra and collateral circulation, more concise imaging parameters are worth exploring\(^7\text{-}^9\). It is known that collateral circulation and time to treatment both affect the transformation from penumbra to infarct core\(^7,^8\). However, the area supplied by lateral lenticulostriate arteries (LSAs) lacking of collateral vessels may play a unique role in acute middle cerebral artery occlusion (MCAO) independent of time and collateral flow. Thus, the objective of this study was to investigate whether the lateral LSAs observed before thrombectomy could predict good clinical outcomes.

**Methods**

**Patients**

From August 2016 to August 2018, we retrospectively collected all the patients presented with acute stroke due to acute M1 segment of middle cerebral artery occlusion were treated with stent-retriever thrombectomy as the first-line endovascular therapy at two comprehensive regional stroke centers, Shanghai East Hospital and Huashan Hospital. 3-month follow-up were acquired blinded through telephone. All patients underwent an initial imaging protocol including nonenhanced computed tomographic (CT) scan, CT perfusion (CTP) and computed tomography angiography (CTA) before commencing endovascular thrombectomy procedures. CTP/CTA imaging was acquired on the 320-slice CT scanner (Aquilion One, Toshiba Medical Systems) and a 64-slice detector scanner
(Discovery CT750 HD; GE Medical Systems, Waukesha, Wisconsin). The inclusion criteria were as follows: (1) acute ischemic stroke, (2) M1 segment of MCAO detected with digital subtraction angiography (DSA), (3) the time from onset to reperfusion therapy was determined by local guidelines at the time\textsuperscript{10,11}. Patients with poor imaging quality were excluded. This study was approved by the Ethics Committee of the Shanghai East hospital and all subjects provided written informed consent.

**Endovascular treatment and DSA assessment**

Solitaire stent and manual aspiration thrombectomy were performed as the first-line endovascular treatment. When stent-retriever thrombectomy was not ideal, intra-arterial recombinant tissue plasminogen activator (rtPA) infusion or stenting was performed. Successful revascularization was defined as a modified thrombolysis in cerebral infarction (mTICI) grade of 2b or 3\textsuperscript{12}.

Two reviewers independently analyzed the pre-interventional DSA. Both readers who had at least three years of training in neuroradiology respectively run blinded to the interventional imaging and all clinical data. The readers determined the presence or absence of lateral LSAs on pre-interventional DSA (see Figure 1 for illustrative cases). The readers repeated his assessment 14 days later blinded to his first assessment in order to evaluate intrarater reliability. In cases of discrepancies, a consensus read was performed with both readers and the third more experienced reader who was not involved in the initial assessment.

**Variables and Clinical assessment**

Baseline data is included age, sex, cigarette smoking, medical history, disease onset, treatment and initial assessment by multi-model CT. the National Institute of Health Stroke Scale (NIHSS) score (scores range from 0-42, with higher scores indicating
increasing severity) were evaluated before thrombectomy, and collateral status based on CTA were evaluated according to previously published criteria. CT perfusion data were postprocessed by a commercial software (MIStar; Apollo Medical Imaging Technology, Melbourne, Australia). The infarct core was defined as a cerebral blood flow (CBF) < 30% and penumbra based on the difference between the core lesion and the delay time (DT) > 3 s lesion. The mismatch ratio was defined as the proportion of DT > 3 s lesion volume (hypoperfusion) with a CBF < 30% lesion volume (core). Symptomatic intracranial haemorrhage (sICH) transformation and were defined according to European Cooperative Acute Stroke Study (ECASS)-III criteria. The recanalization time was defined as interval between symptom onset and first intracranial DSA series. The primary outcome was defined as good outcome (modified Rankin Scale (mRS) score of 0 to 2) at 90 days. And we also evaluated core infarct volume, NIHSS (a NIHSS score of 42 was assigned in cases of death) and mRS at 14 days, sICH, mortality in hospital and at 90 days, recanalization rates as secondary outcomes.

**Statistical analysis**

Statistical analysis for categorical variables included Chi-square test, Fisher exact test when cell sizes were small, and odds ratios for selected comparisons. The measurement data were described as mean±standard deviation if normally distributed or the median and analyzed using Student’s t test or the Mann-Whitney test. Logistic regression analysis was performed to identify independent predictors for clinical outcome. Variables with a P value of < 0.15 in the univariate analysis on clinical outcome were included in a multivariate logistic regression, performed with the forward selection and backward elimination method. A P value of < 0.05 was considered significant. All analytic procedures were conducted in SPSS version 21.0.
Results

We initially identified a total of 60 patients meeting the inclusion criteria. One patient were excluded because of poor imaging quality. Among the leaving 59 patients, the mean age was 69.8±11.2 years, 40 patients (67.8%) were female, and the median baseline NIHSS was 15. 25 patients (42.4%) received intravenous thrombolysis treatment before thrombectomy and the mean door-to-needle time (DNT) was 51 min. On pre-intervention DSA, 36 patients (61%) had the appearance of lateral LSAs (LSA+) and 26 patients (39%) were sparing of the LSAs (LSA-). All the 59 enrolled patients completed the follow-up. The study flow chart was summarized in Figure 2. There was initial disagreement on the group assignment of 2 patients, which represents 96.6% interrater agreement. Consensus was then reached on the final group assignments for these discordant designees.

Baseline data: Baseline demographics and details of the intervention were similar between groups except for NIHSS score before thrombectomy (Table 1). No significant differences were observed between the two groups in relation to age, sex, premorbid history of hypertension, diabetes mellitus, atrial fibrillation, dyslipidemia, ischemic stroke, antiplatelet drugs use, anticoagulation drugs use, cardioembolic source, history of smoking, intravenous thrombolysis, onset-treatment time and successful recanalization between the two groups. The NIHSS score of LSA+ group was significantly lower than that of LSA- group. (P = 0.001) (Table 1).

Clinical outcome: As the primary outcome, the proportion of patients with a modified Rankin score of 0 to 2 at 90 days was 72.2% in the LSA+ group and 8.7% in the LSA- group (OR 27.3, 95% CI 5.38–138.4, P<0.001, Table 2). When compared to the LSA- group, the LSA+ group had a lower risk of symptomatic intracranial haemorrhages (sICH) (8.3% versus 47.8%, OR 0.10, 95% CI 0.02–0.42, P = 0.001) and mortality in hospital (5.6% versus 34.8%, OR 0.11, 95% CI 0.02–0.58, P<0.004). Patients in LSA+ group had lower NIHSS (2
versus 15 P<0.01) and mRS (2 versus 5 P<0.01) at 14 days. There was a significantly smaller core infarct core volume (34ml versus 46ml, P = 0.016) on CTP compared to the LSA- group.

Prognosis: In a univariate analysis, the following variables were identified as predictors of a good outcome: young age (age ≤ 80 years), low NIHSS before thrombectomy (NIHSS ≤ 14), small core infarct volume on CTP (core volume ≤ 50ml) and LSA+ (Tables 3). In a multivariate analysis, a small core infarct volume (OR 6.74, 95% CI 1.148–39.569, P = 0.035) and LSA+ (OR 22.114, 95% CI 3.339–146.470, P = 0.001) were significant independent predictors of good outcome at 3 months (Table 3).

Discussion

This study showed that except the core infarct volume, the the appearance of lateral LSAs on pre-intervention DSA was an independent predictor of good functional outcome at 90 days after thrombectomy in patients with acute M1 segment of MCAO. Only few studies have evaluated the correlation between the appearance of LSAs and basal ganglia infarction after thrombectomy. Kleine et al16 reported that LSAs occlusion patterns predicted infarction in associated striatal subterritories with a positive predictive value of 96%. Similarly, Friedrich et al17 reported that the distance to thrombus in acute middle cerebral artery stroke independently predicts basal ganglia infarction after mechanical thrombectomy with high sensitivity and specificity. However, there is no report on the correlation between the appearance of LSAs and the prognosis of thrombectomy. Our study first reported their correlation and provided a simple and new thought for the decision making of thrombectomy.

It is supposed that patients with LSA+ before intervention wound have a better clinical outcome for several reasons. (1) Although ischemic penumbra is reversible with early
reperfusion, deep brain tissue like basal ganglia and internal capsule which are responsible for the transmission of key neural fiber pathway mainly depends on perforator arteries for blood supply, which have poor collateral circulation\textsuperscript{18}. Once the LSAs are blocked, irreversible ischemic lesions is formed and even with quick and successful revascularization the functional deficits might not reversible\textsuperscript{19}. (2) Hemorrhagic transformation is prone to occur after reperfusion treatment in deep brain tissue supplied by LSAs without collateral flow. In this study, the LSA+ group had a lower risk of sICH (8.3\% versus 47.8\%) compared to the LSA- group.

The study of independent factors determining the effect of thrombectomy is a hot topic of concern. The existing evidence showed that time to treatment, infarct core volume and collateral circulation may be used as reference factors. In particular, the DAWN trial \textsuperscript{20} and DEFUSE–3 trial\textsuperscript{21} suggests that the value of perfusion imaging is more prominent. However, multimodal imaging is not widely used. Thus, we are still in lack of concise imaging signs which are intuitive and easy to popularize. Using DSA to evaluate LSAs has several advantages in clinical application and promotion. First, this imaging marker is routine examined before thrombectomy. In addition, compared with preoperative multi-model imaging (CT or Magnetic resonance), LSAs has advantages of shorter time and easier operation, and provides potentially new decision-making factors for emergency thrombectomy in hospitals without preoperative evaluation of core infarction and ischemic penumbra. This study also confirmed the core infarct volume is an independent prognostic predictors for thrombectomy, which is similar to other studies\textsuperscript{22–24}.

Our study had several limitations, including the retrospective design and limited sample size. In addition, the assessment of LSAs by DSA has limited spatial resolution. Two patients differed in their assessment mainly because of small LSAs not obvious and partial
anatomical variations exists in LSAs. Therefore, it is necessary to expand sample size and develop prospective research to further verify results of the study.

Conclusions

This study suggested that the appearance of LSAs on pre-interventional DSA is a strong predictor of good clinical outcome after stent-retriever thrombectomy in patients with acute M1 segment of MCAO. Our study provided a new thought for the patient selection for thrombectomy especially in those stroke centers without multimodal imaging.

Abbreviations

CBF: cerebral blood flow
CI: Confidence interval
CT: computed tomographic
CTA: computed tomography angiography
CTP: computed tomography perfusion imaging
DNT: door-to needle time
DSA: digital subtraction angiography
DT: delay time
LAO: large artery occlusion
LMCA: left middle cerebral artery
LSAs: lateral lenticulostriate arteries
LSA+: appearing of lateral LSAs
LSA-: sparing of lateral LSAs
MCAO: middle cerebral artery occlusion
mRS: modified Rankin Scale
mTICI: modified thrombolysis in cerebral infarction
NIHSS: National Institute of Health Stroke Scale
OR: Odds Ratio
rtPA: recombinant tissue plasminogen activator
sICH: symptomatic intracranial haemorrhages

Declarations

Ethics approval and consent to participate
This study was approved by the Ethics Committee of the Shanghai East hospital and all subjects provided written informed consent.

Consent for publication
Not applicable.

Availability of data and materials
Study related data and materials are accessible on request from the corresponding author on reasonable request.

Competing Interests
The authors declare that they have no competing interests.

Funding
This work was supported by grants obtained from the Key Disciplines Group Construction Project of Pudong Health Bureau of Shanghai (Grant No. PWZxq2017-08), the Outstanding Leaders Training Program of Pudong New Area Health System of Shanghai (Grant No. PWRI2018-01), Shanghai Science and Technology Commission (Grant No. 16511105000-16511105002) and Chinese Cardiovascular Association-V.G found (2017-CCA-VG-025). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Authors’ contributions
LFF and CC conceived and designed the study, wrote the first draft of the manuscript and analyzed the data. HL, YXY, GMR and LY carried out data collection. SH, XYP and CWJ were responsible for the DSA assessment. DQ and CX revised the paper. LG designed the study and finalized the manuscript. All authors read and approved the final manuscript.

Acknowledgements

We thank all our fellow workers, residents and nursing team at the Department of Neurology in East Hospital and Huashan Hospital for their continuous support of this study.
