Abstract
In this paper, we study the error behavior of the nonequispaced fast Fourier transform (NFFT). This approximate algorithm is mainly based on the convenient choice of a compactly supported window function. So far, various window functions have been used and new window functions have recently been proposed. We present novel error estimates for NFFT with compactly supported, continuous window functions and derive rules for convenient choice from the parameters involved in NFFT. The error constant of a window function depends mainly on the oversampling factor and the truncation parameter.

Keywords Nonequispaced fast Fourier transform · NFFT · Error estimate · Wiener algebra · Oversampling factor · Truncation parameter · Compactly supported window function · Paley–Wiener theorem

1 Introduction
Since the restriction to equispaced data is an essential drawback in several applications of discrete Fourier transform, one has developed fast algorithms for nonequispaced data, the so-called nonequispaced fast Fourier transform (NFFT), see [6,8,11,12,20,24] and [18, Chapter 7].

In this paper we investigate error estimates for the NFFT, where we restrict ourselves to an approximation by translates of a previously selected, continuous window function with compact support. Other approaches based on the fast multipole method and on the low-rank approximation were presented in [9, 22].

After the seminal paper [24], the similarities of the window-based algorithms for NFFT became clear. In the following, we give an overview of the window-based NFFT used so far. In this construction of NFFT, a window function is applied together with its Fourier transform. This connection is very important in order to deduce error estimates for the NFFT. This made it possible to determine convenient parameters of the involved window function. To develop an NFFT, the necessary Fourier coefficients of the periodized window function can simply be calculated by a convenient quadrature rule. A challenge are error estimations in order to determine the parameters of the window function involved. By $C(\mathbb{T})$ we denote the Banach space of all 1-periodic, continuous functions, where $\mathbb{T} = \mathbb{R}/\mathbb{Z}$ is the torus.

The considered window functions depend on some parameters. Assume that $N \in 2\mathbb{N}$ is the order of the given 1-periodic trigonometric polynomial which values will be computed by NFFT. Let $\sigma > 1$ be an oversampling factor such that $N_1 := \sigma N \in 2\mathbb{N}$. For fixed truncation parameter $m \in \mathbb{N} \setminus \{1\}$ with $2m \ll N_1$, we denote by $\Phi_{m, N_1}$ the set of all window functions $\varphi : \mathbb{R} \to [0, 1]$ with the following properties:

- Each window function $\varphi$ is even, has a compact support $[-m/N_1, m/N_1]$, and is continuous on $\mathbb{R}$.
- Each restricted window function $\varphi|_{[0, m/N_1]}$ is decreasing with $\varphi(0) = 1$ and $\varphi(m/N_1) = 0$.
- For each window function $\varphi$, the Fourier transform

$$\hat{\varphi}(v) := \int_{\mathbb{R}} \varphi(t) e^{-2\pi i vt} \, dt = 2 \int_{0}^{m/N_1} \varphi(t) \cos(2\pi vt) \, dt$$

is positive for all $v \in [-N/2, N/2]$.

Note that for fixed $N_1$ the truncation parameter $m$ determines the size of the support of $\varphi \in \Phi_{m, N_1}$. If a window function $\varphi \in \Phi_{m, N_1}$ has the form

$$\varphi(x) = \frac{1}{\varphi_1(\beta \varphi_2(0))} \varphi_1(\beta \varphi_2(x)) \quad x \in \mathbb{R},$$

with $\beta > 0$ and convenient functions $\varphi_1, \varphi_2$, then $\beta$ is a so-called shape parameter of $\varphi$. Examples of window functions of the set $\Phi_{m, N_1}$ are the B-spline window function (28), the modified B-spline window function (30), the algebraic window function (31), the Bessel window function (39), the sinh-type window function (45) and the related window functions (see Sect. 5.5) as well as the modified cosh-type window function (46) and the related window functions (see Sect. 5.6). Note that the Kaiser–Bessel window function (see [18, p. 393]) and the Gaussian window function (see [18, p. 390]) are not contained in $\Phi_{m, N_1}$, since these window functions are supported on whole $\mathbb{R}$. 

© Birkhäuser
The aim of this paper is a systematic approach to uniform error estimates for NFFT, where a compactly supported, continuous window function \( \varphi \in \Phi_{m,N_1} \) is used. We introduce the \( C(\mathbb{T}) \)-error constant

\[
e_{\sigma}(\varphi) = \sup_{N \in 2\mathbb{N}} \left( \max_{n \in I_N} \left\| \sum_{r \in \mathbb{Z} \setminus \{0\}} \frac{\hat{\varphi}(n + rN_1)}{\hat{\varphi}(n)} e^{2\pi i r N_1} \right\|_{C(\mathbb{T})} \right)
\]

where \( I_N \) denotes the index set \( \{-N/2, 1-N/2, \ldots, N/2-1\} \). As shown in Lemma 2, the uniform error of the NFFT with nonequispaced spatial data and equispaced frequencies can be estimated by \( e_{\sigma}(\varphi) \). Analogously in Lemma 4, the error of the NFFT with nonequispaced frequencies and equispaced spatial data is estimated by \( e_{\sigma}(\varphi) \) too. Therefore in the following, we study mainly the behavior of the \( C(\mathbb{T}) \)-error constant \( e_{\sigma}(\varphi) \). Our main result is Theorem 2, where we describe a general concept for the construction of a convenient upper bound for the \( C(\mathbb{T}) \)-error constant \( e_{\sigma}(\varphi) \) with a window function \( \varphi \in \Phi_{m,N_1} \). Applying Theorem 2, we obtain upper bounds for \( e_{\sigma}(\varphi) \) with special window function \( \varphi \in \Phi_{m,N_1} \). We show that the \( C(\mathbb{T}) \)-error constant \( e_{\sigma}(\varphi) \) of a window function \( \varphi \in \Phi_{m,N_1} \) depends mainly on the oversampling factor \( \sigma > 1 \) and the truncation parameter \( m \in \mathbb{N} \setminus \{1\} \). Since we are interested in NFFT with relatively low computational cost, the oversampling factor \( \sigma \in \left[ \frac{5}{4}, 2 \right] \) and the truncation parameter \( m \in \{2, 3, \ldots, 6\} \) are restricted. These parameters \( \sigma \) and \( m \) determine the shape parameter \( \beta \) of the window function. For the Bessel window function (39), the sinh-type window function (45), and the modified cosh-type window function (46), a good choice is the shape parameter \( \beta = 2\pi m \left( 1 - \frac{1}{2\sigma} \right) \).

In connection with NFFT, B-spline window functions were first investigated in [6]. In the important application of particle simulation (see [7]), the B-spline window function was also used. Later it became clear that these methods can be interpreted as a special case of the fast summation method, see [15,19] and the references therein. Based on this unified approach, one can use all the other window functions for this application too. The convenient choice of the shape parameter is of special importance, as shown in [14] for the root mean square error of the NFFT.

In this paper we suggest four new continuous, compactly supported window functions for the NFFT, namely the algebraic, Bessel, sinh-type, and modified cosh-type window function. The algebraic window function is very much related to the B-spline window function, but much simpler to compute. We show that the Bessel window function (39), sinh-type window function (45), and modified cosh-type window function (46) are very convenient for NFFT, since they possess very small \( C(\mathbb{T}) \)-error constants with exponential decay with respect to \( m \). It is difficult to design a window function \( \varphi \in \Phi_{m,N_1} \) with minimal \( C(\mathbb{T}) \)-error constant. We prove that the best error behavior has the modified cosh-type window function (46) with the shape parameter \( \beta = 2\pi m \left( 1 - \frac{1}{2\sigma} \right), \sigma \geq \frac{5}{4} \). Further we compare several window functions with respect to the corresponding \( C(\mathbb{T}) \)-error constants for the NFFT. Based on the error estimates of the sinh-type window function, we are able to extend the error estimates, see [21], to window functions where an analytical expression of its Fourier transform is unknown, see [3–5].
We prefer the use of compactly supported, continuous window functions \( \varphi \in \Phi_{m,N_1} \) by the following reasons:

- As explained in Remark 1, the NFFT with a window function \( \varphi \in \Phi_{m,N_1} \) is simpler than the NFFT with a window function supported on whole \( \mathbb{R} \).
- The window functions \( \varphi \in \Phi_{m,N_1} \) presented in Section 5 (and their Fourier transforms) have simple explicit forms and they are convenient as window functions for NFFT.
- Few window functions \( \varphi \in \Phi_{m,N_1} \) (such as Bessel, sinh-type, and modified cosh-type window function) possess low \( C(\mathbb{T}) \)-error constants with exponential decay with respect to \( m \). Up to now, the best error behavior has the modified cosh-type window function.

The outline of the paper is as follows. In Sect. 2 we introduce the basic definitions and develop the error estimates for an NFFT with a general compactly supported, continuous window function. Important tools for the estimation of the Fourier transforms of window functions are developed in Sect. 3. In Sect. 4 we present a modified Paley–Wiener Theorem which characterizes the behavior of Fourier transforms of compactly supported functions lying in a special Sobolev space. The main results of this paper are contained in Sect. 5. Using the uniform norm, we present explicit error estimates for the (modified) B-spline, algebraic, Bessel, sinh-type, and modified cosh-type window functions. Further we show numerical tests so that the \( C(\mathbb{T}) \)-error constants of the different window functions can be easily compared.

2 Convenient window functions for NFFT

Let \( \tilde{\varphi} : \mathbb{T} \to [0, 1] \) be the 1-periodization of \( \varphi \), i.e.,

\[
\tilde{\varphi}(x) := \sum_{k \in \mathbb{Z}} \varphi(x + k), \quad x \in \mathbb{T}. \tag{1}
\]

Note that for each \( x \in \mathbb{R} \) the series (1) has at most one nonzero term. Then the Fourier coefficients of \( \tilde{\varphi} \) read as follows

\[
c_k(\tilde{\varphi}) := \int_{0}^{1} \tilde{\varphi}(t) e^{-2\pi i k t} \, dt = \hat{\varphi}(k), \quad k \in \mathbb{Z}.
\]

By the properties of the window function \( \varphi \in \Phi_{m,N_1} \), the 1-periodic function \( \tilde{\varphi} \) is continuous on \( \mathbb{T} \) and of bounded variation over \( [-\frac{1}{2}, \frac{1}{2}] \). Then from the Convergence Theorem of Dirichlet–Jordan (see [27, Vol. 1, pp. 57–58]), it follows that \( \tilde{\varphi} \) possesses the uniformly convergent Fourier expansion

\[
\tilde{\varphi}(x) = \sum_{k \in \mathbb{Z}} c_k(\tilde{\varphi}) e^{2\pi i k x}, \quad x \in \mathbb{R}. \tag{2}
\]
Lemma 1 For given \( \varphi \in \Phi_{m,N_1} \), the series

\[
\sum_{r \in \mathbb{Z}} c_{n+rN_1}(\tilde{\varphi}) e^{2\pi i (n+rN_1)x}
\]

is convergent for each \( x \in \mathbb{R} \) and has the sum

\[
\frac{1}{N_1} \sum_{\ell=0}^{N_1-1} e^{-2\pi i n \ell/N_1} \tilde{\varphi}(x + \frac{\ell}{N_1})
\]

which coincides with the rectangular rule of the integral

\[
c_n(\tilde{\varphi}(x + \cdot)) = \int_0^1 \tilde{\varphi}(s + x) e^{-2\pi i ns} ds = c_n(\tilde{\varphi}) e^{2\pi i nx}.
\]

Proof From (2) it follows that for all \( n \in \mathbb{Z} \) and \( x \in \mathbb{R} \) it holds

\[
e^{-2\pi i nx} \tilde{\varphi}(x) = \sum_{k \in \mathbb{Z}} c_{k+n}(\tilde{\varphi}) e^{2\pi i kx}.
\]

Replacing \( x \) by \( x + \frac{\ell}{N_1} \) with \( \ell = 0, \ldots, N_1 - 1 \), we obtain

\[
e^{-2\pi i n (x+\ell/N_1)} \tilde{\varphi}(x + \frac{\ell}{N_1}) = \sum_{k \in \mathbb{Z}} c_{k+n}(\tilde{\varphi}) e^{2\pi i kx} e^{2\pi i k\ell/N_1}.
\]

Summing the above formulas for \( \ell = 0, \ldots, N_1 - 1 \) and using the known relation

\[
\sum_{\ell=0}^{N_1-1} e^{2\pi i k\ell/N_1} = \begin{cases} N_1 & k \equiv 0 \mod N_1, \\ 0 & k \not\equiv 0 \mod N_1, \end{cases}
\]

we conclude that

\[
\sum_{\ell=0}^{N_1-1} e^{-2\pi i n (x+\ell/N_1)} \tilde{\varphi}(x + \frac{\ell}{N_1}) = N_1 \sum_{r \in \mathbb{Z}} c_{n+rN_1}(\tilde{\varphi}) e^{2\pi i rN_1x}.
\]

This completes the proof. \( \square \)

2.1 NFFT with nonequispaced spatial data and equispaced frequencies

Let \( M \in 2\mathbb{N} \) and \( I_M := \{-M/2, 1 - M/2, \ldots, M/2 - 1\} \) be given. The NFFT with nonequispaced spatial data and equispaced frequencies is an approximate, fast
algorithm which computes approximately the values \( f(x_j), j \in I_M \), of a 1-periodic trigonometric polynomial

\[
f(x) := \sum_{k \in I_N} c_k(f) e^{2\pi i k x}
\]  

(3)

at \( M \) nonequispaced nodes \( x_j \in [-\frac{1}{2}, \frac{1}{2}), j \in I_M \). Using a window function \( \varphi \in \Phi_{m,N_1} \), the trigonometric polynomial \( f \) is approximated by the 1-periodic function

\[
s(x) := \sum_{\ell \in I_{N_1}} g_\ell \tilde{\varphi}(x - \frac{\ell}{N_1})
\]  

(4)

with conveniently chosen coefficients \( g_\ell \in \mathbb{C} \). The computation of the values \( s(x_j), j \in I_M \), which approximate \( f(x_j) \) is very easy. Since \( \varphi \) is compactly supported and thus \( \tilde{\varphi} \) is well-localized, each value \( s(x_j), j \in I_M \), is equal to a sum of few nonzero terms.

The coefficients \( g_\ell \) can be determined by discrete Fourier transform (DFT) as follows. The 1-periodic function \( s \) possesses the Fourier expansion

\[
s(x) = \sum_{k \in \mathbb{Z}} c_k(s) e^{2\pi i k x}
\]

with the Fourier coefficients

\[
c_k(s) = \int_0^1 s(t) e^{-2\pi i k t} dt = \hat{g}_k c_k(\tilde{\varphi}), \quad k \in \mathbb{Z},
\]

where

\[
\hat{g}_k := \sum_{\ell \in I_{N_1}} g_\ell e^{-2\pi i k \ell/N_1}.
\]

In other words, the vector \((\hat{g}_k)_{k \in I_{N_1}}\) is the DFT of length \( N_1 \) of coefficient vector \((g_\ell)_{\ell \in I_{N_1}}\) such that

\[
\hat{g}_k = \hat{g}_{k+N_1}, \quad k \in \mathbb{Z}.
\]

In order to approximate \( f \) by \( s \), we set

\[
\hat{g}_k = \begin{cases} 
\frac{c_k(f)}{\hat{c}_k(\varphi)} & k \in I_N, \\
0 & k \in I_{N_1} \setminus I_N.
\end{cases}
\]

Note that the values \( \hat{g}_k, k \in I_N \), can be used in an efficient way. Even if (3) is only known at finitely many equispaced points of \([0, 1]\), the Fourier coefficients \( c_k(f), k \in I_N \), can be approximately determined by a fast Fourier transform (FFT). For
many window functions $\varphi \in \Phi_{m,N_1}$, the Fourier coefficients $c_k(\hat{\varphi})$, $k \in I_N$, are explicitly known.

Then for all $r \in \mathbb{Z}$, it holds

$$c_{n+rN_1}(s) = \hat{g}_n c_{n+rN_1}(\hat{\varphi}) = \begin{cases} c_n(f) \frac{c_{n+rN_1}(\hat{\varphi})}{c_n(\hat{\varphi})} & n \in I_N, \\ 0 & n \in I_{N_1} \setminus I_N. \end{cases}$$

In particular, we see that $c_n(s) = c_n(f)$ for all $n \in I_N$ and $c_n(s) = 0$ for all $n \in I_{N_1} \setminus I_N$. Substituting $k = n + rN_1$ with $n \in I_{N_1}$ and $r \in \mathbb{Z}$, we obtain

$$s(x) - f(x) = \sum_{k \in \mathbb{Z} \setminus I_{N_1}} c_k(s) e^{2\pi i k x} = \sum_{n \in I_{N_1}} \sum_{r \in \mathbb{Z} \setminus \{0\}} c_{n+rN_1}(s) e^{2\pi i (n+rN_1) x}$$

$$= \sum_{n \in I_N} c_n(f) \left( \sum_{r \in \mathbb{Z} \setminus \{0\}} \frac{c_{n+rN_1}(\hat{\varphi})}{c_n(\hat{\varphi})} e^{2\pi i (n+rN_1) x} \right)$$

$$= \sum_{n \in I_N} c_n(f) \left( \sum_{r \in \mathbb{Z} \setminus \{0\}} \frac{\hat{\varphi}(n + rN_1)}{\hat{\varphi}(n)} e^{2\pi i (n+rN_1) x} \right).$$

(5)

Let $A(\mathbb{T})$ be the Wiener algebra of all 1-periodic functions $g \in L_1(\mathbb{T})$ with the property

$$\sum_{k \in \mathbb{Z}} |c_k(g)| < \infty.$$ 

Then

$$\|g\|_{A(\mathbb{T})} := \sum_{k \in \mathbb{Z}} |c_k(g)|$$

is the norm of $A(\mathbb{T})$. Obviously, we have $A(\mathbb{T}) \subset C(\mathbb{T})$, where $C(\mathbb{T})$ denotes the Banach space of all 1-periodic, continuous functions with the uniform norm

$$\|g\|_{C(\mathbb{T})} := \max_{x \in \mathbb{T}} |g(x)|.$$ 

Since $x_j \in [-\frac{1}{2}, \frac{1}{2})$, $j \in I_M$, are arbitrary nodes, we have

$$|s(x_j) - f(x_j)| \leq \|s - f\|_{C(\mathbb{T})}.$$ 

Therefore we measure the error of NFFT $\|s - f\|_{C(\mathbb{T})}$ in the uniform norm. As norm of the 1-periodic trigonometric polynomial (3) we use the norm in the Wiener algebra $A(\mathbb{T})$.

**Remark 1** The NFFT with a window function of the set $\Phi_{m,N_1}$ is simpler than the NFFT with Kaiser–Bessel or Gaussian window function $\varphi$, since both window functions are supported on whole $\mathbb{R}$. For such a window function $\varphi$, an additional step in the NFFT.
is necessary, where the 1-periodic function (4) is approximated by the 1-periodic well-localized function

\[ s_1(x) := \sum_{\ell \in I_{N_1}} g_{\ell} \tilde{\psi} \left( x - \frac{\ell}{N_1} \right), \]

where \( \tilde{\psi} \) is the 1-periodization of the truncated window function (see [18, pp. 378–381])

\[ \psi(x) := \begin{cases} \varphi(x) & x \in [-m/N_1, m/N_1], \\ 0 & x \in \mathbb{R} \setminus [-m/N_1, m/N_1]. \end{cases} \]

Thus the NFFT with a window function \( \varphi \) supported on whole \( \mathbb{R} \) requires also a truncated version of \( \varphi \). In this case, the error of the NFFT is measured by \( \|s_1 - f\|_{C(\mathbb{T})} \). In [18, p. 393], it is shown that the error of the NFFT with the Kaiser–Bessel window function can be estimated by

\[ \|s_1 - f\|_{C(\mathbb{T})} \leq 4m^{3/2} e^{-2\pi m^{1/\sigma}} \|f\|_{A(\mathbb{T})}. \]

We will see in Subsections 5.4–5.6 that special window functions \( \varphi \in \Phi_{m,N_1} \) possess a similar error behavior as the Kaiser–Bessel window function.

We say that the window function \( \varphi \in \Phi_{m,N_1} \) is convenient for NFFT, if the \( C(\mathbb{T}) \)-error constant

\[ e_\sigma(\varphi) := \sup_{N \in 2\mathbb{N}} e_{\sigma,N}(\varphi) \]

with

\[ e_{\sigma,N}(\varphi) := \max_{n \in I_N} \left\| \sum_{r \in \mathbb{Z} \setminus \{0\}} \frac{\hat{\varphi}(n + r N_1)}{\hat{\varphi}(n)} e^{2\pi i r N_1} \cdot \|_{C(\mathbb{T})}, \quad N \in 2\mathbb{N}, \]

fulfills the condition \( e_\sigma(\varphi) \ll 1 \) for conveniently chosen truncation parameter \( m \geq 2 \) and oversampling factor \( \sigma > 1 \). Later in Theorem 2 we will show that under certain assumptions on \( \varphi \in \Phi_{m,N_1} \) the value \( e_{\sigma,N}(\varphi) \) is bounded for all \( N \in \mathbb{N} \). This \( C(\mathbb{T}) \)-error constant is motivated by techniques first used in [24] and later also in [5]. G. Steidl [24] has applied this technique for error estimates of NFFT with B-spline and Gaussian window functions, respectively.

**Lemma 2** For each \( N \in 2\mathbb{N} \), the constant \( e_{\sigma,N}(\varphi) \) of \( \varphi \in \Phi_{m,N_1} \) can be represented in the equivalent form

\[ e_{\sigma,N}(\varphi) = \max_{n \in I_N} \left\| \frac{1}{N_1 c_n(\varphi)} \sum_{\ell=0}^{N_1-1} e^{-2\pi i n \ell/N_1} \tilde{\varphi}(\cdot + \frac{\ell}{N_1}) - e^{2\pi i n} \right\|_{C(\mathbb{T})}. \]
Proof By Lemma 1 we know that for all $x \in \mathbb{T}$ it holds
\[
\left( \sum_{r \in \mathbb{Z} \setminus \{0\}} c_{n+rN_1} (\tilde{\phi}) e^{2\pi i r N_1 x} \right) e^{2\pi i nx} = \sum_{r \in \mathbb{Z} \setminus \{0\}} c_{n+rN_1} (\tilde{\phi}) e^{2\pi i (n+rN_1) x}
\]
\[
= \frac{1}{N_1} \sum_{\ell=0}^{N_1-1} e^{-2\pi i n \ell / N_1} \tilde{\phi}(x + \frac{\ell}{N_1}) - c_n(\tilde{\phi}) e^{2\pi i nx}
\]
and hence
\[
\left\| \sum_{r \in \mathbb{Z} \setminus \{0\}} \frac{c_{n+rN_1}(\tilde{\phi})}{c_n(\tilde{\phi})} e^{2\pi i r N_1} \right\|_{C(T)} = \left\| \frac{1}{N_1} \sum_{\ell=0}^{N_1-1} e^{-2\pi i n \ell / N_1} \tilde{\phi}(\cdot + \frac{\ell}{N_1}) - e^{2\pi i nx} \right\|_{C(T)}
\]

This completes the proof. \hfill \Box

Thus the condition $e_\sigma (\phi) \ll 1$ with (7) means that each exponential
\[
e^{2\pi i n \cdot}, \ n \in I_N,
\]
can be approximately reproduced by a linear combination of shifted window functions $\tilde{\phi}(\cdot + \frac{\ell}{N_1})$ with $\ell \in I_{N_1}$. In other words, the equispaced shifts $\tilde{\phi}(\cdot + \frac{\ell}{N_1})$ with $\ell \in I_{N_1}$ are approximately exponential reproducing. For each node $x_j \in [-\frac{1}{2}, \frac{1}{2})$, $j \in I_M$, the linear combination
\[
\frac{1}{N_1} c_n(\tilde{\phi}) \sum_{\ell=0}^{N_1-1} e^{-2\pi i n \ell / N_1} \tilde{\phi}(x_j + \frac{\ell}{N_1})
\]
has only few nonzero terms, since the support of $\phi$ is very small for large $N_1$. If we replace $\exp(2\pi i nx_j)$ for each $n \in I_N$ and $j \in I_M$ by the approximate value (8), we compute approximate values of
\[
f(x_j) \approx \sum_{n \in I_N} c_n(f) e^{2\pi i n x_j}, \ j \in I_M,
\]
in the form
\[
f(x_j) \approx \frac{1}{N_1} \sum_{\ell \in I_{N_1}} \left( \sum_{n \in I_N} \frac{c_n(f)}{c_n(\tilde{\phi})} e^{-2\pi i n \ell / N_1} \right) \tilde{\phi}(x_j + \frac{\ell}{N_1})
\]
mainly by DFT. This is the key of the NFFT with nonequispaced spatial data and equispaced frequencies. Special window functions $\phi \in \Phi_{m,N_1}$ which are convenient for NFFT will be presented in Sect. 5.
Lemma 3 Let $\sigma > 1$, $m \in \mathbb{N}\setminus\{1\}$, $N \in 2\mathbb{N}$, and $N_1 = \sigma N \in 2\mathbb{N}$ be given. Further let $\varphi \in \Phi_{m,N_1}$. Let $f$ be a 1-periodic trigonometric polynomial (3) and $s$ its approximating 1-periodic function (4).

Then the error of NFFT with nonequispaced spatial data and equispaced frequencies can be estimated by

\[ \|s - f\|_{C(T)} \leq e_\sigma(\varphi) \|f\|_{A(T)}. \]  

(9)

Proof From (5) it follows that

\[ s(x) - f(x) = \sum_{n \in I_N} c_n(f) \left( \sum_{r \in \mathbb{Z}\setminus\{0\}} \frac{c_{n+rN} \hat{\varphi}}{c_n \hat{\varphi}} e^{2\pi i (n+rN) x} \right). \]

Note that $c_n(\hat{\varphi}) = \hat{\phi}(n) > 0$ for $n \in I_N$ by assumption $\varphi \in \Phi_{m,N_1}$. Then by Hölder’s inequality we obtain that for all $x \in T$ it holds

\[ |s(x) - f(x)| \leq \sum_{n \in I_N} |c_n(f)| \left( \max_{n \in I_N} \left| \sum_{r \in \mathbb{Z}\setminus\{0\}} \frac{c_{n+rN_1} \hat{\phi}}{c_n \hat{\phi}} e^{2\pi i rN_1 x} \right| \right) \]

\[ = \sum_{n \in I_N} |c_n(f)| \left( \max_{n \in I_N} \left| \sum_{r \in \mathbb{Z}\setminus\{0\}} \hat{\phi}(n + rN_1) e^{2\pi i rN_1 x} \right| \right) \]

\[ \leq e_\sigma(\varphi) \|f\|_{A(T)} < \infty. \]

Hence we get (9). \(\Box\)

Remark 2 Let $\lambda \geq 0$ be fixed. We introduce the 1-periodic Sobolev space $H^\lambda(T)$ of all 1-periodic functions $f : T \rightarrow \mathbb{C}$ which are integrable on $[0, 1]$ and for which

\[ \|f\|_{H^\lambda(T)} := \left( \sum_{k \in \mathbb{Z}} |k|^{2\lambda} |c_k(f)|^2 \right)^{1/2} < \infty, \]

where we declare $|0| := 1$. Then $H^\lambda(T)$ is a Hilbert space with the inner product

\[ \langle f, g \rangle_{H^\lambda(T)} := \sum_{k \in \mathbb{Z}} |k|^{2\lambda} c_k(f) c_k(g). \]

For $\lambda = 0$, we have $H^0(T) = L^2(T)$. Then the Sobolev embedding theorem (see [23, p. 142]) says that for $\lambda > \frac{1}{2}$ it holds $H^\lambda(T) \subset A(T) \subset C(T)$. Let $f$ be a 1-periodic, trigonometric polynomial of the form (3). Then we have

\[ \|f\|_{C(T)} \leq \sum_{k \in I_N} |c_k(f)| = \|f\|_{A(T)} = \sum_{k \in I_N} (|c_k(f)| |k|^{\lambda}) |k|^{-\lambda}. \]
Applying the Cauchy–Schwarz inequality, we obtain for \( \lambda > \frac{1}{2} \) that
\[
\| f \|_{C(T)} \leq \| f \|_{A(T)} \leq \left( \sum_{k \in I_N} (|c_k(f)|^2 |k|^{2\lambda}) \right)^{1/2} \left( \sum_{k \in I_N} |k|^{-2\lambda} \right)^{1/2} \\
\leq \| f \|_{H^\lambda(T)} \left( 1 + 2 \sum_{k=1}^{\infty} \frac{1}{k^{2\lambda}} \right)^{1/2}.
\]

Using the Riemann zeta function \( \zeta(2\lambda) := \sum_{k=1}^{\infty} \frac{1}{k^{2\lambda}}, \lambda > \frac{1}{2} \), we obtain the following inequality
\[
\| f \|_{C(T)} \leq \| f \|_{A(T)} \leq \| f \|_{H^\lambda(T)} \sqrt{1 + 2 \zeta(2\lambda)}.
\]

Thus under the assumptions of Lemma 3, the error of NFFT with nonequispaced spatial data and equispaced frequencies can be estimated by
\[
\| s - f \|_{C(T)} \leq e_{\sigma}(\varphi) \sqrt{1 + 2 \zeta(2\lambda)} \| f \|_{H^\lambda(T)}.
\]

Note that
\[
\zeta(2) = \frac{\pi^2}{6}, \quad \zeta(4) = \frac{\pi^4}{90}, \quad \zeta(6) = \frac{\pi^6}{945}, \quad \zeta(8) = \frac{\pi^8}{9450}, \quad \zeta(10) = \frac{\pi^{10}}{93555} < 1.000995.
\]

### 2.2 NFFT with nonequispaced frequencies and equispaced spatial data

The NFFT with nonequispaced frequencies and equispaced spatial data or transposed NFFT evaluates the exponential sums
\[
s_k := \sum_{j \in I_M} f_j e^{2\pi i k x_j}, \quad k \in I_N,
\]
for arbitrary given coefficients \( f_j \in \mathbb{C} \) and nonequispaced frequencies \( x_j \in \left[-\frac{1}{2}, \frac{1}{2}\right), j \in I_M \). Assume that the window function \( \varphi \in \Phi_{m,N_1} \) is convenient for NFFT. Introducing the 1-periodic function
\[
g(x) := \sum_{j \in I_M} f_j \tilde{\varphi}(x_j + x),
\]
the Fourier coefficients of \( g \) read as follows
\[
c_k(g) = \int_0^1 g(t) e^{-2\pi i k t} \, dt = \left( \sum_{j \in I_M} f_j e^{2\pi i k x_j} \right) c_k(\tilde{\varphi}) = s_k c_k(\tilde{\varphi}), \quad k \in \mathbb{Z}.
\]
Using the trapezoidal rule, we approximate $c_k(g)$ by

$$
\tilde{c}_k(g) := \frac{1}{N_1} \sum_{\ell \in I_{N_1}} \sum_{j \in I_M} f_j \tilde{\phi}(x_j + \frac{\ell}{N_1}) e^{-2\pi i k \ell/N_1}.
$$

Note that $\tilde{c}_k(g)$, $k \in I_N$, can be efficiently computed by FFT, for details see [18, p. 382]. Then the results of this NFFT with nonequispaced frequencies and equispaced spatial data are the values

$$
\tilde{s}_k := \frac{\tilde{c}_k(g)}{c_k(\tilde{\phi})}, \quad k \in I_N.
$$

It is interesting that the same $C(\mathbb{T})$-error constant (6) appears in an error estimate of the NFFT with nonequispaced frequencies and equispaced spatial data too.

**Lemma 4** Let $\sigma > 1$, $m \in \mathbb{N}\setminus\{1\}$, $N, M \in 2\mathbb{N}$, and $N_1 = \sigma N \in 2\mathbb{N}$. Further let $\varphi \in \Phi_{m,N_1}$. For given $f_j \in \mathbb{C}$ and nonequispaced frequencies $x_j \in [-\frac{1}{2}, \frac{1}{2})$, $j \in I_M$, we consider the exponential sums (10) and the related approximations (11).

Then the error of NFFT with nonequispaced frequencies and equispaced spatial data can be estimated by

$$
\max_{k \in I_N} |s_k - \tilde{s}_k| \leq e_\sigma(\varphi) \sum_{j \in I_M} |f_j|.
$$

**Proof** For each $k \in I_N$ we have

$$
|s_k - \tilde{s}_k| = \frac{1}{c_k(\tilde{\phi})} |c_k(g) - \tilde{c}_k(g)|
= \left| \sum_{j \in I_M} f_j \left( e^{2\pi i k x_j} - \frac{1}{N_1 c_k(\tilde{\phi})} \sum_{\ell \in I_{N_1}} \tilde{\phi}(x_j + \frac{\ell}{N_1}) e^{-2\pi i k \ell/N_1} \right) \right|.
$$

From Hölder’s inequality and Lemma 2 it follows that

$$
|s_k - \tilde{s}_k| \leq \max_{j \in I_M} \left| e^{2\pi i k x_j} - \frac{1}{N_1 c_k(\tilde{\phi})} \sum_{\ell \in I_{N_1}} \tilde{\phi}(x_j + \frac{\ell}{N_1}) e^{-2\pi i k \ell/N_1} \right| \sum_{j \in I_M} |f_j|
\leq e_{\sigma,N}(\varphi) \sum_{j \in I_M} |f_j| \leq e_\sigma(\varphi) \sum_{j \in I_M} |f_j|.
$$

This completes the proof. \(\square\)

**3 Auxiliary estimates**

In our study we use later the following
Lemma 5 For $-1 < u < 1$ and $\mu > 1$ it holds

$$\sum_{r \in \mathbb{Z} \setminus \{0, \pm 1\}} |u + r|^{-\mu} \leq \frac{2}{\mu - 1} (1 - |u|)^{1-\mu}.$$  

Proof For $-1 < u < 1, r \in \mathbb{N},$ and $\mu > 1$ we have

$$|u + (-1)^j r|^{-\mu} \leq (r - |u|)^{-\mu}, \quad j = 0, 1. \quad (12)$$

Using (12), the series can be estimated as follows

$$\sum_{r = 2}^{\infty} |u + (-1)^j r|^{-\mu} \leq \sum_{r = 2}^{\infty} (r - |u|)^{-\mu}, \quad j = 0, 1.$$

Hence it follows by the integral test for convergence that

$$\sum_{r \in \mathbb{Z} \setminus \{0, \pm 1\}} |u + r|^{-\mu} = \sum_{r = 2}^{\infty} |u + r|^{-\mu} + \sum_{r = 2}^{\infty} |u - r|^{-\mu} \leq 2 \sum_{r = 2}^{\infty} (r - |u|)^{-\mu}$$

$$\leq 2 \int_{1}^{\infty} (x - |u|)^{-\mu} \, dx = \frac{2}{\mu - 1} (1 - |u|)^{1-\mu}.$$  

For fixed $\mu \geq 0$, the $\mu$th Bessel function of first kind is defined by

$$J_\mu(x) := \sum_{k=0}^{\infty} \frac{(-1)^k}{2^{\mu+2k} k! \Gamma(\mu + k + 1)} x^{\mu+2k}, \quad x \geq 0,$$

so that in particular

$$J_m(x) := \sum_{k=0}^{\infty} \frac{(-1)^k}{2^m 2^{m+2k} k! (m + k)!} x^{m+2k}, \quad m = 0, 1, \ldots.$$

For fixed $\mu \geq 0$, the $\mu$th modified Bessel function of first kind is defined by

$$I_\mu(x) := \sum_{k=0}^{\infty} \frac{1}{2^{\mu+2k} k! \Gamma(\mu + k + 1)} x^{\mu+2k}, \quad x \geq 0,$$

so that in particular

$$I_m(x) := \sum_{k=0}^{\infty} \frac{1}{2^m 2^{m+2k} k! (m + k)!} x^{m+2k}, \quad m = 0, 1, \ldots.$$
For the properties of Bessel functions we refer to [1, pp. 355–478] and [25]. In particular, these Bessel functions possess the following asymptotic behaviors for \( x \to \infty \) (see [1, pp. 364, 377]),

\[
J_\mu(x) \sim \sqrt{\frac{2}{\pi x}} \cos \left( x - \frac{\mu \pi}{2} - \frac{\pi}{4} \right) \left( 1 + \mathcal{O}(x^{-1}) \right),
\]

(13)

\[
I_\mu(x) \sim \frac{1}{\sqrt{2\pi x}} e^x \left( 1 - \frac{4\mu^2 - 1}{8x} + \mathcal{O}(x^{-2}) \right).
\]

(14)

Here we are interested in explicit error estimates for NFFT with compactly supported, continuous window function. For this purpose, we need explicit bounds for the Bessel functions instead of the asymptotic formulas (13) and (14).

**Lemma 6** For fixed \( \mu > \frac{1}{2} \) and all \( x \geq 0 \), it holds

\[
|x^2 - \mu^2 + \frac{1}{4}|^{1/4} |J_\mu(x)| < \sqrt{\frac{2}{\pi}},
\]

(15)

where \( \sqrt{\frac{2}{\pi}} \) is the best possible upper bound. In particular for \( \mu = 1 \) and \( x \geq 6 \), we have

\[
|J_1(x)| < \frac{1}{\sqrt{x}}.
\]

For \( \mu = \frac{5}{2} \) and \( x \geq 6 \), we have

\[
|J_{5/2}(x)| < \frac{1}{\sqrt{x}}.
\]

(16)

For \( \mu = 3m \) with \( m \in \mathbb{N} \setminus \{1\} \) and \( x \geq \pi m \), we have

\[
|J_{3m}(x)| < \frac{3}{2\sqrt{x}}.
\]

(17)

Further for all \( x \in \mathbb{R} \) with \( |x| \geq \pi \), it holds

\[
|J_0(x)| < \frac{1}{2}.
\]

(18)

**Proof** The inequality (15) was shown in [13]. For \( \mu = 1 \), the inequality (15) means that

\[
|x^2 - \frac{3}{4}|^{1/4} |J_1(x)| < \sqrt{\frac{2}{\pi}}.
\]
Thus for all \( x \geq 6 \) we have

\[
c \sqrt{x} \leq \left| x^2 - \frac{3}{4} \right|^{1/4}
\]

with the constant

\[
c = \min_{x \geq 6} \left| x^2 - \frac{3}{4} \right|^{1/4} = \min_{x \geq 6} \left( 1 - \frac{3}{4x^2} \right)^{1/4} = (1 - \frac{1}{48})^{1/4} = 0.994750 \ldots
\]

such that

\[
|J_1(x)| \leq \frac{1}{0.994750} \sqrt{\frac{2}{\pi x}} < \frac{1}{\sqrt{x}}.
\]

Similarly, one can show the inequalities (16) and (17).

Since \( J_0 \) is even, we prove the inequality (18) only for positive \( x \). By [25, p. 206], the Bessel function \( J_0(x) \) can be represented for \( x > 0 \) in the form

\[
J_0(x) = \sqrt{\frac{2}{\pi x}} \left[ \cos \left( x - \frac{\pi}{4} \right) P(x) - \sin \left( x - \frac{\pi}{4} \right) Q(x) \right],
\]

where \( P(x) \) and \( Q(x) \) are certain functions as defined in [25, p. 205]. By [25, p. 208], these functions can be estimated as follows

\[
0 \leq P(x) \leq 1 - \frac{1^2 3^2}{2! (8x)^2} + \frac{1^2 3^2 5^2 7^2}{4! (8x)^4},
\]

\[
-\frac{1}{8x} \leq Q(x) \leq 0.
\]

Applying the Cauchy–Schwarz inequality to

\[
\frac{\pi x}{2} J_0(x)^2 = \left[ \cos \left( x - \frac{\pi}{4} \right) P(x) - \sin \left( x - \frac{\pi}{4} \right) Q(x) \right]^2,
\]

we obtain for \( x \geq 2 \),

\[
\frac{\pi x}{2} J_0(x)^2 \leq \left( \cos^2 \left( x - \frac{\pi}{4} \right) + \sin^2 \left( x - \frac{\pi}{4} \right) \right) \left( P(x)^2 + Q(x)^2 \right)
\]

\[
\leq \left( 1 - \frac{1^2 3^2}{2! (8x)^2} + \frac{1^2 3^2 5^2 7^2}{4! (8x)^4} \right)^2 + \frac{1}{(8x)^2}
\]

\[
\leq \left( 1 - \frac{1^2 3^2}{2! (8x)^2} + \frac{1^2 3^2 5^2 7^2}{4! 16 (8x)^2} \right)^2 + \frac{1}{(8x)^2}
\]

\[
= 1 - \frac{4517}{65536 x^2} + \frac{30702681}{17179869184 x^4} < 1
\]
such that

\[ |J_0(x)| < \sqrt{\frac{2}{\pi x}}, \quad x \geq 2. \]

Hence it follows that for \( x \geq \pi \),

\[ |J_0(x)| < \frac{\sqrt{2}}{\pi} < \frac{1}{2}. \]

This completes the proof. \( \square \)

**Lemma 7** Let \( \mu \geq \frac{1}{2} \) and \( x_0 > 0 \) be given. Then for all \( x \geq x_0 \), it holds

\[ \sqrt{2\pi x_0} e^{-x_0} I_\mu(x_0) \leq \sqrt{2\pi} x e^{-x} I_\mu(x) < 1. \] (19)

**Proof** By [2, Inequality (2.6)] one knows that for fixed \( \mu \geq \frac{1}{2} \) and arbitrary \( x, y \in (0, \infty) \) with \( x < y \) it holds

\[ \frac{I_\mu(x)}{I_\mu(y)} < \sqrt{\frac{y}{x}} e^{x-y}, \]

i.e.,

\[ \sqrt{2\pi} x e^{-x} I_\mu(x) < \sqrt{2\pi} y e^{-y} I_\mu(y). \]

Hence the function \( f(x) := \sqrt{2\pi} x e^{-x} I_\mu(x) \) is strictly increasing on \( (0, \infty) \). Further by (14) we have

\[ \lim_{y \to \infty} \sqrt{2\pi} y e^{-y} I_\mu(y) = 1. \]

This implies the inequality (19). \( \square \)

### 4 Paley–Wiener theorem in a Sobolev space

The main tool of this approach is the study of the Fourier transform \( \hat{\varphi}(v) \) of \( \varphi \in \Phi_{m,N_1} \) for \( |v| \to \infty \). A rapid decay of \( \hat{\varphi} \) is essential for a small \( C(\mathbb{T}) \)-error constant (6). From Fourier analytical point of view, it is very interesting to discuss the relation to the known Theorem of Paley–Wiener (see [17, pp. 12–13]), since this result characterizes the behavior of Fourier transforms of functions \( \varphi \) which vanish outside the open interval \( I = \left( -\frac{m}{N_1}, \frac{m}{N_1} \right) \). The smoothness of the restricted window function \( \varphi|_I \) determines the decay of \( \hat{\varphi}(v) \) for \( |v| \to \infty \).

For simplicity, we denote functions defined on \( I \) by \( \varphi \) too. By \( H^k(I), \ k \in \mathbb{N} \), we denote the Sobolev space of all functions \( \varphi \in L^2(I) \) with \( D^j\varphi \in L^2(I), \ j = 1, \ldots, k \),
where $D_j \varphi$ is the $j$th weak derivative of $\varphi$. Then $H^k(I)$ is a Hilbert space with the Sobolev norm

$$
\| \varphi \|_{H^k(I)} := \left( \sum_{j=0}^{k} \| D_j \varphi \|_{L^2(I)}^2 \right)^{1/2}.
$$

Further we define the Sobolev space $H^k_0(I)$ as the closure in $H^k(I)$ of the space $C_\infty^0(I)$ which consists of all infinitely differentiable, locally supported functions. Then $H^k_0(I)$ is the set of all functions $\varphi \in H^k(I)$ with vanishing one-sided derivatives

$$
\varphi^{(j)}(\pm \frac{m}{N_1}) = 0, \quad j = 0, \ldots, k - 1.
$$

We present the following modification of the Theorem of Paley–Wiener (cf. [17, pp. 12–13] or [27, Vol. II, pp. 272–274]):

**Theorem 1** For given $\varphi \in H^k_0(I)$ with $k \in \mathbb{N}$, the function

$$
f(z) := \int_I \varphi(t) e^{-2\pi i z t} \, dt, \quad z = x + i y \in \mathbb{C},
$$

is entire and has the following properties:

1. For real variable $x$, it holds $f(x) \in L^2(\mathbb{R})$ and $x^k f(x) \in L^2(\mathbb{R})$.
2. For all $z \in \mathbb{C}$, there exist a positive constant $\gamma_k(\varphi)$ such that

$$
|f(z)| \leq \gamma_k(\varphi) (1 + |2\pi z|)^{-k} e^{2\pi m |\text{Im} z|/N_1}.
$$

Conversely, if an entire function $f$ satisfies the conditions 1. and 2., then the function

$$
\varphi(x) := \int_\mathbb{R} f(t) e^{2\pi i x t} \, dt, \quad x \in \mathbb{R},
$$

has the properties $\varphi|_I \in H^k(I)$ and $\varphi|_{\mathbb{R}\setminus I} = 0$. Note that

$$
\int_\mathbb{R} f(t) e^{2\pi i x t} \, dt := \lim_{R \to \infty} \int_{-R}^{R} f(t) e^{2\pi i x t} \, dt
$$

means the limit in $L^2(\mathbb{R})$ and that $\varphi|_{\mathbb{R}\setminus I} = 0$ means $\varphi(x) = 0$ for almost all $x \in \mathbb{R}\setminus I$.

**Proof** Let $\varphi \in H^k_0(I)$ be given, i.e., $D^j \varphi \in L^2(I)$, $j = 0, \ldots, k$, and

$$
\varphi^{(j)}(\pm \frac{m}{N_1}) = 0, \quad j = 0, \ldots, k - 1.
$$

(20)

For arbitrary $z = x + i y \in \mathbb{C}$ and $t \in \bar{I}$ we have

$$
|e^{-2\pi i z t}| = |e^{-2\pi i x t}| e^{2\pi |y| t} \leq e^{2\pi |y| |t|} \leq e^{2\pi m |\text{Im} z|/N_1} \leq 2\pi m |\text{Im} z|/N_1
$$
and hence
\[ |f(z)| = \left| \int_I \varphi(t) e^{-2\pi i z t} \, dt \right| \leq \left( \int_I |\varphi(t)| \, dt \right) e^{2\pi m |\text{Im} z|/N_1}. \] (21)

Since by the Schwarz inequality
\[ \|\varphi\|_{L^1(I)} = \int_I |\varphi(t)| \cdot 1 \, dt \leq \|\varphi\|_{L^2(I)} \|1\|_{L^2(I)} = \frac{2m}{N_1} \|\varphi\|_{L^2(I)} < \infty, \] (22)
we have \( \varphi \in L^1(I) \) too. Since \( D^j \varphi \in L^2(I) \) for \( j = 1, \ldots, k \), we have \( D^j \varphi \in L^1(I) \) analogously to (22).

Obviously, \( f \) is an entire function, because for each \( z \in \mathbb{C} \) and \( j \in \mathbb{N} \) it holds
\[ f^{(j)}(z) = \int_I \varphi(t) (-2\pi i t)^j e^{-2\pi i z t} \, dt = (-2\pi i)^j \int_I t^j \varphi(t) e^{-2\pi i z t} \, dt. \]

Using (20), repeated integration by parts applied to the function \( \varphi \) gives for \( j = 1, \ldots, k \) the equalities
\[ \int_I \varphi(t) \left( \frac{d^j}{dt^j} e^{-2\pi i z t} \right) \, dt = (-1)^j \int_I (D^j \varphi)(t) e^{-2\pi i z t} \, dt \]
such that
\[ (-2\pi i)^j f(z) = \int_I \varphi(t) \left( \frac{d^j}{dt^j} e^{-2\pi i z t} \right) \, dt = (-1)^j \int_I (D^j \varphi)(t) e^{-2\pi i z t} \, dt. \] (23)

Hence we obtain
\[ |2\pi z|^j |f(z)| \leq \left( \int_I |(D^j \varphi)(t)| \, dt \right) e^{2\pi m |\text{Im} z|/N_1}. \] (24)

From (21) and (24) it follows that for all \( z \in \mathbb{C} \) it holds
\[ (1 + |2\pi z|)^k |f(z)| \leq \gamma_k(\varphi) e^{2\pi m |\text{Im} z|/N_1} \]
with the positive constant
\[ \gamma_k(\varphi) := \binom{k}{0} \int_I |\varphi(t)| \, dt + \binom{k}{1} \int_I |(D \varphi)(t)| \, dt + \ldots + \binom{k}{k} \int_I |(D^k \varphi)(t)| \, dt < \infty. \]

By (23) with \( j = k \), we have for \( x \in \mathbb{R} \) the equalities
\[ (-2\pi i x)^k f(x) = (-1)^k \int_I (D^k \varphi)(t) e^{-2\pi i x t} \, dt = (-1)^k \int_{\mathbb{R}} (D^k \varphi)(t) e^{-2\pi i x t} \, dt \]

\( \text{Birkhäuser} \)
such that $x^k f(x) \in L^2(I)$ by the Theorem of Plancherel.

Now we assume that an entire function $f$ with the properties 1. and 2. is given. Then especially we have $f|_{\mathbb{R}} \in L^2(\mathbb{R})$ and

$$|f(z)| \leq \gamma_k(\varphi) e^{2\pi m |\text{Im}z|/N_1}, \quad z \in \mathbb{C}.$$ 

By the original Theorem of Paley–Wiener, the function

$$\varphi(x) := \int_{\mathbb{R}} f(t) e^{2\pi i tx} \, dt \in L^2(\mathbb{R})$$

vanishes for almost all $x \in \mathbb{R}\setminus I$ such that $\varphi|_{I} \in L^2(I)$. For $t \in \mathbb{R}$, from $f(t) \in L^2(\mathbb{R})$ and $t^k f(t) \in L^2(\mathbb{R})$ it follows $t^j f(t) \in L^2(\mathbb{R})$, $j = 1, \ldots, k - 1$, since $|t^j f(t)|^2 \leq |f(t)|^2$ for $t \in [-1, 1]$ and $|t^j f(t)|^2 \leq |t^k f(t)|^2$ for $t \in \mathbb{R}\setminus[-1, 1]$.

Each function in $L^2(\mathbb{R})$ generates a tempered distribution. By the differentiation property of the Fourier transform of tempered distributions we conclude that the $j$th weak derivative of $\varphi$ exists almost everywhere and that

$$(D^j \varphi)(x) = \int_{\mathbb{R}} (2\pi i t)^j f(t) e^{2\pi i tx} \, dt \in L^2(\mathbb{R}), \quad j = 1, \ldots, k.$$ 

Now we have to show that $D^j \varphi|_{\mathbb{R}\setminus I} = 0$. From property 2. of the entire function $f$ it follows that the entire function $(2\pi i z)^j f(z)$ with $j = 1, \ldots, k$ fulfills the inequality

$$|(2\pi i z)^j f(z)| = |2\pi z|^j |f(z)| \leq \gamma_k(\varphi) \frac{|2\pi z|^j}{(1 + |2\pi z|)^k} e^{2\pi m |\text{Im}z|/N_1} \leq \gamma_k(\varphi) e^{2\pi m |\text{Im}z|/N_1}$$

for all $z \in \mathbb{C}$. Applying the original Theorem of Paley–Wiener to the entire function $(2\pi i z)^j f(z)$, we see that

$$\psi_j(x) := \int_{\mathbb{R}} (2\pi i t)^j f(t) e^{2\pi i tx} \, dt$$

vanishes almost everywhere in $\mathbb{R}\setminus I$. Since $\psi_j(x) = (D^j \varphi)(x) = 0$ almost everywhere, we have $(D^j \varphi)(x) = 0$ for almost all $x \in \mathbb{R}\setminus I$. Hence we have $D^j \varphi|_{I} \in L^2(I)$ for $j = 1, \ldots, k$ such that $\varphi|_{I} \in H^k(I)$. This completes the proof. \hfill $\square$

Unfortunately, the assumption $\varphi \in H^k_0(I)$ is too strong for the most popular window function.

**Example 1** The triangular function $\varphi(x) := 1 - \frac{N_1}{m} |x|$, $x \in I$, belongs to the Sobolev space $H^1_0(I)$, but doesn’t belong to $H^2_0(I)$, since it holds $\varphi(\pm \frac{m}{N_1}) = 0$ and $\varphi'(\pm \frac{m}{N_1}) \neq 0$. In this case, we obtain that for $z \in \mathbb{C}$,

$$f(z) = \int_{-m/N_1}^{m/N_1} \varphi(t) e^{-2\pi i zt} \, dt = 2 \int_{0}^{m/N_1} (1 - \frac{N_1}{m} t) \cos(2\pi z t) \, dt$$
\[
\frac{2m}{N_1} \int_0^1 (1 - s) \cos \left( \frac{2\pi m}{N_1} zs \right) ds = \frac{m}{N_1} \left( \text{sinc} \frac{\pi m z}{N_1} \right)^2
\]

with
\[
\text{sinc} z := \begin{cases} 
\sin z / z & z \in \mathbb{C}\setminus\{0\}, \\
1 & z = 0.
\end{cases}
\]

Thus Theorem 1 results in \( k = 1 \). Otherwise we observe a quadratic decay of the Fourier transform \( \hat{\varphi} \), since for \( x \in \mathbb{R}\setminus\{0\} \),
\[
|f(x)| = |\hat{\varphi}(x)| \leq \frac{N_1}{m\pi^2} |x|^{-2}.
\]

Hence we will present a better method in the following Theorem 2.

### 5 Special window functions

In this section, we determine upper bounds of the error constant (6) for various special window functions \( \varphi \in \Phi_{m,N_1} \) by two methods. If the series
\[
\sum_{n \in \mathbb{Z}} |\hat{\varphi}(n)| < \infty,
\]
then by (6) we have that
\[
e_\sigma(\varphi) \leq \sup_{N \in 2\mathbb{N}} \left( \max_{n \in I_N} \sum_{r \in \mathbb{Z}\setminus\{0\}} |\hat{\varphi}(n + rN_1)| \right). \tag{25}
\]

This technique can be applied for (modified) B-spline window functions.

For the algebraic, Bessel, sinh-type, and modified cosh-type window functions, we use the following argument. By Hölder’s inequality it follows from (6) that
\[
e_\sigma(\varphi) \leq \sup_{N \in 2\mathbb{N}} \left( \min_{n \in I_N} \hat{\varphi}(n) \right)^{-1} \max_{n \in I_N} \left\| \sum_{r \in \mathbb{Z}\setminus\{0\}} \hat{\varphi}(n + rN_1) e^{2\pi i r N_1 / N} \right\|_{C(\mathbb{T})}.
\]

Thus we show that the minimum of all \( \hat{\varphi}(n) \) for relatively low frequencies \( n \in I_N \) is equal to \( \hat{\varphi}(N/2) \) and that the series
\[
\sum_{r \in \mathbb{Z}\setminus\{0\}} |\hat{\varphi}(n + rN_1)|
\]

\( \copyright \) Birkhäuser
is bounded for each $n \in I_N$. For this we have to estimate the Fourier transform $\hat{\phi}(n)$ for sufficiently large frequencies $|n| \geq N_1 - \frac{N}{2}$ very carefully. Thus this results in

$$ e_\sigma(\phi) \leq \sup_{N \in 2\mathbb{N}} \left( \frac{1}{\phi(N/2)} \max_{n \in I_N} \sum_{r \in \mathbb{Z} \setminus \{0\}} |\hat{\phi}(n + rN_1)| \right). $$

Now we use the special structure of the given window function $\phi$. Let $m \in \mathbb{N} \setminus \{1\}$ and $\sigma > 1$ be given. Assume that an even, continuous function $\phi_0 : \mathbb{R} \to [0, 1]$ with $\text{supp} \phi_0 = [-1, 1]$ has following properties: $\phi_0(0) = 1$, $\phi_0|_{[0, 1]}$ is decreasing, and its restricted Fourier transform $\hat{\phi}_0|_{[0, m/(2\sigma)]}$ is positive and decreasing. Let $N \in 2\mathbb{N}$ with $N_1 = \sigma N \in 2\mathbb{N}$ be given. Then the scaled function

$$ \varphi(x) := \phi_0 \left( \frac{N_1 x}{m} \right), \quad x \in \mathbb{R}, $$

is a continuous window function of the set $\Phi_{m,N_1}$.

**Theorem 2** Let $\sigma > 1$, $m \in \mathbb{N} \setminus \{1\}$, $N \in 2\mathbb{N}$, and $N_1 = \sigma N \in 2\mathbb{N}$ be given. Further let $\varphi \in \Phi_{m,N_1}$ be a scaled version (26) of $\phi_0$. Assume that the Fourier transform $\hat{\phi}_0$ fulfills the decay condition

$$ |\hat{\phi}_0(v)| \leq \begin{cases} c_1 |v| \in \left[ m \left( 1 - \frac{1}{2\sigma} \right), m \left( 1 + \frac{1}{2\sigma} \right) \right], \\ c_2 |v|^{-\mu} |v| \geq m \left( 1 + \frac{1}{2\sigma} \right), \end{cases} $$

with certain constants $c_1 > 0$, $c_2 > 0$, and $\mu > 1$.

Then the constant $e_{\sigma,N}(\varphi)$ is bounded for all $N \in 2\mathbb{N}$ by

$$ e_{\sigma,N}(\varphi) \leq \frac{1}{\hat{\phi}_0 \left( \frac{m}{2\sigma} \right)} \left[ 2c_1 + \frac{2c_2}{(\mu - 1) m^\mu (1 - \frac{1}{2\sigma})^{1-\mu}} \right]. $$

Further, the $C(\mathbb{T})$-error constant $e_\sigma(\varphi)$ of the window function (26) has the upper bound

$$ e_\sigma(\varphi) \leq \frac{1}{\hat{\phi}_0 \left( \frac{m}{2\sigma} \right)} \left[ 2c_1 + \frac{2c_2}{(\mu - 1) m^\mu (1 - \frac{1}{2\sigma})^{1-\mu}} \right]. $$

**Proof** Note that it holds

$$ |\hat{\phi}_0(v)| \leq \int_{\mathbb{R}} \varphi_0(x) \, dx = \hat{\phi}_0(0), \quad v \in \mathbb{R}. $$

By the scaling property of the Fourier transform, we have

$$ \hat{\phi}(v) = \int_{\mathbb{R}} \varphi(x) e^{-2\pi i vx} \, dx = \frac{m}{N_1} \hat{\phi}_0 \left( \frac{mv}{N_1} \right), \quad v \in \mathbb{R}. $$
For all \( n \in I_N \) and \( r \in \mathbb{Z}\setminus\{0, \pm 1\} \), we obtain

\[
\left| \frac{mn}{N_1} + mr \right| \geq m \left( 2 - \frac{1}{2\sigma} \right) > m \left( 1 + \frac{1}{2\sigma} \right)
\]

and hence

\[
|\hat{\phi}(n + rN_1)| = \frac{m}{N_1} \left| \hat{\phi}_0 \left( \frac{mn}{N_1} + mr \right) \right| \leq \frac{mc_2}{m^\mu N_1} \left| \frac{n}{N_1} + r \right|^{-\mu}.
\]

From Lemma 5 it follows that for fixed \( u = \frac{n}{N_1} \in \left[ -\frac{1}{2\sigma}, \frac{1}{2\sigma} \right] \),

\[
\sum_{r \in \mathbb{Z}\setminus\{0, \pm 1\}} |u + r|^{-\mu} \leq \frac{2}{\mu - 1} \left( 1 - \frac{1}{2\sigma} \right)^{1-\mu}.
\]

For all \( n \in I_N \), we sustain

\[
|\hat{\phi}(n \pm N_1)| = \frac{m}{N_1} \left| \hat{\phi}_0 \left( \frac{mn}{N_1} \pm m \right) \right| \leq \frac{m}{N_1} c_1,
\]

since

\[
\left| \frac{mn}{N_1} \pm m \right| \in \left[ m \left( 1 - \frac{1}{2\sigma} \right), m \left( 1 + \frac{1}{2\sigma} \right) \right].
\]

Thus we estimate for each \( n \in I_N \),

\[
\sum_{r \in \mathbb{Z}\setminus\{0\}} |\hat{\phi}(n + rN_1)| \leq \frac{m}{N_1} \left[ \left| \hat{\phi}_0 \left( \frac{mn}{N_1} - m \right) \right| + \left| \hat{\phi}_0 \left( \frac{mn}{N_1} + m \right) \right| 
\right.

\[
+ \sum_{k \in \mathbb{Z}\setminus\{0, \pm 1\}} \left| \hat{\phi}_0 \left( \frac{mn}{N_1} + mr \right) \right| \right]

\[
\leq \frac{m}{N_1} \left[ 2c_1 + \frac{c_2}{m^\mu} \sum_{r \in \mathbb{Z}\setminus\{0, \pm 1\}} \left| \frac{n}{N_1} + r \right|^{-\mu} \right]

\[
\leq \frac{m}{N_1} \left[ 2c_1 + \frac{2c_2}{(\mu - 1)m^\mu} \left( 1 - \frac{1}{2\sigma} \right)^{1-\mu} \right] .
\]

Now we determine the minimum of all positive values

\[
\hat{\phi}(n) = \frac{m}{N_1} \hat{\phi}_0 \left( \frac{mn}{N_1} \right), \quad n \in I_N.
\]

Since \( \frac{m|n|}{N_1} \leq \frac{m}{2\sigma} \) for all \( n \in I_N \), we obtain

\[
\min_{n \in I_N} \hat{\phi}(n) = \frac{m}{N_1} \min_{n \in I_N} \hat{\phi}_0 \left( \frac{mn}{N_1} \right) = \frac{m}{N_1} \hat{\phi}_0 \left( \frac{m}{2\sigma} \right) = \hat{\phi} \left( \frac{N}{2} \right) > 0.
\]
Thus we see that the constant $e_{\sigma,N}(\varphi)$ can be estimated by an upper bound which depends on $m$ and $\sigma$, but does not depend on $N$. We obtain
\[
e_{\sigma,N}(\varphi) \leq \frac{1}{\hat{\varphi}(N/2)} \max_{n \in I_N} \sum_{r \in \mathbb{Z}\setminus\{0\}} |\hat{\varphi}(n + rN)| \leq \frac{1}{\hat{\varphi}_0(\frac{m}{2\sigma})} \left[ 2c_1 + \frac{2c_2}{(\mu - 1) m^\mu} \left(1 - \frac{1}{2\sigma}\right)^{1-\mu}\right].
\]
Consequently, the $C(\mathbb{T})$-error constant $e_{\sigma}(\varphi)$ has the upper bound (27). \qed

In the following, we show that for our study, Theorem 2 is more convenient than Theorem 1 (cf. Example 1).

**Example 2** For $m = 2$ and $\sigma > 1$, we consider the triangular window function (26) with
\[
\varphi_0(x) := \begin{cases} 1 - |x| & x \in [-1, 1], \\ 0 & x \in \mathbb{R}\setminus[-1, 1]. \end{cases}
\]
Then the Fourier transform of $\varphi_0$ reads as follows
\[
\hat{\varphi}_0(v) = \int_{-1}^{1} (1 - |t|) e^{-2\pi i vt} \, dt = 2 \int_{0}^{1} (1 - t) \cos(2\pi vt) \, dt = \left(\text{sinc}(\pi v)\right)^2.
\]
Obviously, $\varphi_0$ is an even, continuous function with $\text{supp} \varphi_0 = [-1, 1]$, where $\varphi_0(0) = 1$ and $\varphi_0|_{[0, 1]}$ is decreasing. The restricted Fourier transform $\hat{\varphi}_0|_{[0, 1/\sigma]}$ is positive and decreasing. Further $\hat{\varphi}_0$ fulfills the decay condition
\[
|\hat{\varphi}_0(v)| \leq \begin{cases} 1 & |v| \in [2 - 1/\sigma, 2 + 1/\sigma], \\ \frac{1}{\pi^2} |v|^{-2} & |v| \geq 2 + 1/\sigma. \end{cases}
\]
Using Theorem 2, we obtain the following upper bound of the $C(\mathbb{T})$-error constant
\[
e_{\sigma}(\varphi) \leq \left(\text{sinc}\frac{\pi}{\sigma}\right)^2 \left[2 + \frac{1}{2\pi^2} \left(1 - \frac{1}{2\sigma}\right)^{-1}\right].
\]
Note that a better result will be presented in Theorem 3 (for $m = 1$).

### 5.1 B-spline window function

We start with the popular B-spline window function (see [6,24]). Assume that $N \in 2\mathbb{N}$ and $\sigma > 1$ with $N_1 = \sigma N \in 2\mathbb{N}$ are given. We consider the B-spline window function
\[
\varphi_B(x) := \frac{1}{M_{2m}(0)} M_{2m}(N_1 x), \quad (28)
\]
where $M_{2m}$ denotes the centered cardinal B-spline of even order $2m$ with $m \in \mathbb{N}$. For $m = 1$, we obtain the triangular window function. Using the three-term recursion

$$M_m(x) = \frac{x + \frac{m}{2}}{m-1} M_{m-1}(x + \frac{1}{2}) + \frac{\frac{m}{2} - x}{m-1} M_{m-1}(x - \frac{1}{2}), \quad m = 2, 3, \ldots, \ (29)$$

with

$$M_1(x) := \begin{cases} 
1 & x \in (-\frac{1}{2}, \frac{1}{2}), \\
\frac{1}{2} & x \in \{-\frac{1}{2}, \frac{1}{2}\}, \\
0 & x \in \mathbb{R}\setminus[-\frac{1}{2}, \frac{1}{2}]. 
\end{cases}$$

we find

$$M_2(0) = 1, \quad M_4(0) = \frac{2}{3}, \quad M_6(0) = \frac{11}{20}, \quad M_8(0) = \frac{151}{315}.$$ 

Note that $M_{2m}(0) > 0$ for all $m \in \mathbb{N}$, since it holds $M_{2m}(x) > 0$ for each $x \in (-m, m)$. As known, the Fourier transform of (28) (see [18, p. 452]) has the form

$$\hat{\varphi}_B(v) = \frac{1}{N_1 M_{2m}(0)} \left( \frac{\pi v}{N_1} \right)^{2m}, \quad v \in \mathbb{R}.$$ 

If $\tilde{\varphi}_B$ is the 1-periodization (1) of $\varphi_B$, then the Fourier coefficients of $\tilde{\varphi}_B$ read as follows

$$c_k(\tilde{\varphi}_B) = \int_0^1 \tilde{\varphi}_B(t) e^{-2\pi ikx} \, dt = \hat{\varphi}_B(k) = \frac{1}{N_1 M_{2m}(0)} \left( \frac{\pi k}{N_1} \right)^{2m} \geq 0.$$ 

Note that $c_k(\tilde{\varphi}_B) > 0$ for all $k \in I_N$.

By (5) we see that

$$\|s - f\|_{C(\mathbb{T})} \leq \sum_{n \in I_N} |c_n(f)| \sum_{r \in \mathbb{Z} \setminus \{0\}} \frac{c_{n+rN_1}(\tilde{\varphi}_B)}{c_n(\tilde{\varphi}_B)}.$$ 

Now we estimate the $C(\mathbb{T})$-error constants for NFFT. Applying the special structure of the Fourier coefficients $c_k(\tilde{\varphi}_B)$ and Lemma 5, we obtain a good upper bound (25) of the $C(\mathbb{T})$-error constant by this method. For a proof of the following result see [24].

**Theorem 3** Let $\sigma > 1$, $N \in 2 \mathbb{N}$, and $N_1 = \sigma N \in 2 \mathbb{N}$. Further $m \in \mathbb{N}$ with $2m \ll N_1$ is given. Then the $C(\mathbb{T})$-error constant (6) of the B-spline window function (28) can be estimated by

$$e_{\sigma}(\varphi_B) \leq \frac{4m}{2m-1} (2\sigma - 1)^{-2m},$$

i.e., the B-spline window function (28) is convenient for NFFT.
5.2 Modified B-spline window function

Let $\sigma \geq 1$, $m \in \mathbb{N}\{1\}$, $N \in 2\mathbb{N}$, and $N_1 = \sigma N$ be given. The approach to the B-spline window function (28) can be generalized to the modified B-spline window function (see [14])

$$\varphi_{mb}(x) := \frac{1}{M_{2b}(0)} M_{2b}\left(\frac{N_1 b}{m} x\right),$$  \(30\)

where $M_{2b}$ denotes the centered cardinal B-spline of order $2b \in \mathbb{N}\{1, 2\}$, i.e., $b \in \left\{\frac{3}{2}, 2, \frac{5}{2}, \ldots\right\}$. Assume that $N_1 b \in 2\mathbb{N}$ and that $m \in \mathbb{N}$ fulfills the conditions $m < 2\sigma b$ and $b \neq m$. Using the three-term recursion (29), we find $M_3(0) = \frac{3}{4}$, $M_5(0) = \frac{115}{192}$. Obviously, it holds $\varphi_{mb} \in \Phi_{m,N_1}$, where the Fourier transform of (30) (see [18, p. 452]) reads as follows

$$\hat{\varphi}_{mb}(v) = \frac{m}{N_1 b} \left(\frac{\text{sinc} \frac{m\pi v}{N_1 b}}{2b}\right)^2, \quad v \in \mathbb{R}.$$

If $\tilde{\varphi}_{mb}$ denotes the 1-periodization of (30), then the Fourier coefficients of $\tilde{\varphi}_{mb}$ have the following form

$$c_k(\tilde{\varphi}_{mb}) = \int_0^1 \tilde{\varphi}_{mb}(t) e^{-2\pi i k x} dt = \hat{\varphi}_{mb}(k) = \frac{m}{N_1 b} \left(\frac{\text{sinc} \frac{m\pi k}{N_1 b}}{2b}\right)^2.$$

Note that $c_k(\tilde{\varphi}_{mb}) > 0$ for all $k \in I_N$. Let $f$ be an arbitrary 1-periodic trigonometric polynomial (3) which we approximate by the 1-periodic function $s(x) := \sum_{\ell \in I_{N_1 b}} g_{\ell} \tilde{\varphi}_{mb}(x - \frac{\ell}{N_1 b})$

with conveniently chosen coefficients $g_{\ell} \in \mathbb{C}$. Then $s$ possesses the Fourier expansion

$$s(x) = \sum_{k \in \mathbb{Z}} c_k(s) e^{2\pi i k x}$$

with the Fourier coefficients

$$c_k(s) = \int_0^1 s(t) e^{-2\pi i k x} dt = \hat{g}_k c_k(\tilde{\varphi}_{mb}),$$

where

$$\hat{g}_k = \sum_{\ell \in I_{N_1 b}} g_{\ell} e^{-2\pi i k \ell/(N_1 b)}.$$
Thus the vector \((\hat{g}_k)_{k \in I_{N_1 b}}\) is equal to the DFT of length \(N_1 b\) of the vector \((g_\ell)_{\ell \in I_{N_1 b}}\) and we have \(\hat{g}_k + rN_1 b = \hat{g}_k\) for all \(k \in I_{N_1 b}\) and \(r \in \mathbb{Z}\). In order to approximate \(f\) by \(s\), we choose

\[
\hat{g}_k = \begin{cases} 
\frac{c_k(f)}{c_k(\tilde{\phi}_{mB})} & k \in I_N, \\
0 & k \in I_{N_1 b} \setminus I_N.
\end{cases}
\]

Thus we see that \(c_k(s) = c_k(f)\) for all \(k \in I_N\) and \(c_k(s) = 0\) for all \(k \in I_{N_1 b} \setminus I_N\). Substituting \(k = n + rN_1 b\) with \(n \in I_{N_1 b}\) and \(r \in \mathbb{Z}\), we obtain

\[
s(x) - f(x) = \sum_{k \in \mathbb{Z} \setminus I_{N_1 b}} c_k(s) e^{2\pi i k x} = \sum_{n \in I_{N_1 b}} \sum_{r \in \mathbb{Z} \setminus \{0\}} c_{n+rN_1 b}(s) e^{2\pi i (n+rN_1 b) x} = \sum_{n \in I_N} \sum_{r \in \mathbb{Z} \setminus \{0\}} c_n(f) \frac{1}{c_n(\tilde{\phi}_{mB})} c_{n+rN_1 b}(\tilde{\phi}_{mB}) e^{2\pi i (n+rN_1 b) x}
\]

such that

\[
|s(x) - f(x)| \leq \sum_{n \in I_N} |c_n(f)| \sum_{r \in \mathbb{Z} \setminus \{0\}} \left| \frac{|c_{n+rN_1 b}(\tilde{\phi}_{mB})|}{c_n(\tilde{\phi}_{mB})} \right|.
\]

Then it follows by Hölder’s inequality that

\[
\|s - f\|_{C(T)} \leq \left( \sum_{n \in I_N} |c_n(f)| \right)^{\frac{1}{p}} \max_{n \in I_N} \sum_{r \in \mathbb{Z} \setminus \{0\}} \left| \frac{|c_{n+rN_1 b}(\tilde{\phi}_{mB})|}{c_n(\tilde{\phi}_{mB})} \right|^{\frac{1}{q}} = \|f\|_{A(T)} \max_{n \in I_N} \sum_{r \in \mathbb{Z} \setminus \{0\}} \left| \frac{|c_{n+rN_1 b}(\tilde{\phi}_{mB})|}{c_n(\tilde{\phi}_{mB})} \right|.
\]

**Theorem 4** Let \(\sigma \geq 1\), \(N \in 2\mathbb{N}\), \(2b \in \mathbb{N} \setminus \{1, 2\}\), and \(N_1 b \in 2\mathbb{N}\) with \(N_1 = \sigma N\). Further let \(m \in \mathbb{N}\) with \(2b > m\) and \(b \neq m\) be given.

Then the \(C(T)\)-error constant of NFFT with the modified B-spline window function (30) can be estimated by

\[
e_{\sigma b}(\phi_{mB}) \leq \frac{4b}{2b - 1} (2\sigma b - 1)^{-2b},
\]

i.e., the modified B-spline window function (30) is convenient for NFFT.

**Proof** Now we estimate

\[
\max_{n \in I_N} \sum_{r \in \mathbb{Z} \setminus \{0\}} \left| \frac{|c_{n+rN_1 b}(\tilde{\phi}_{mB})|}{c_n(\tilde{\phi}_{mB})} \right|.
\]
For $n = 0$ and $r \in \mathbb{Z} \setminus \{0\}$ we have

$$\left| c_{rN_1b}(\tilde{\varphi}_{mb}) \right| = 0.$$ 

For $n \in I_N \setminus \{0\}$ and $r \in \mathbb{Z} \setminus \{0\}$ we obtain

$$\frac{|c_{n+rN_1b}(\tilde{\varphi}_{mb})|}{c_n(\tilde{\varphi}_{mb})} = \frac{|n|^{2b}}{|n + rN_1b|^{2b}} = \left( \frac{|n|}{N_1b} \right)^{2b} \left| \frac{n}{N_1b} + r \right|^{-2b} \leq \left( \frac{1}{2\sigma b} \right)^{2b} \left| \frac{n}{N_1b} + r \right|^{-2b},$$

since for $n \in I_N$ it holds

$$\frac{|n|}{N_1b} \leq \frac{1}{2\sigma b} \leq \frac{1}{3}.$$ 

Using Lemma 5, we conclude that

$$\sum_{r \in \mathbb{Z} \setminus \{0\}} \frac{|c_{n+rN_1b}(\tilde{\varphi}_{mb})|}{c_n(\tilde{\varphi}_{mb})} \leq \frac{1}{(2\sigma b)^{2b}} \sum_{r \in \mathbb{Z} \setminus \{0\}} \left| \frac{n}{N_1b} + r \right|^{-2b} \leq \frac{1}{(2\sigma b)^{2b}} \left[ 2 \left( 1 - \frac{|n|}{N_1b} \right)^{-2b} + \sum_{r \in \mathbb{Z} \setminus \{0, \pm 1\}} \left| \frac{n}{N_1b} + r \right|^{-2b} \right] \leq \frac{4b}{(2b - 1)(2\sigma b)^{2b}} \left( 1 - \frac{1}{2\sigma b} \right)^{-2b} = \frac{4b}{2b - 1} (2\sigma b - 1)^{-2b}$$

with $2\sigma b \geq 3$. 

\[\square\]

### 5.3 Algebraic window function

For fixed shape parameter $\beta = 3m$ with $m \in \mathbb{N} \setminus \{1\}$ and for an oversampling factor $\sigma > \frac{\pi}{3}$, we consider the algebraic window function

$$\varphi_{alg}(x) := \begin{cases} (1 - \frac{(N_1x)^2}{m^2})^{\beta - 1/2} & x \in [-\frac{m}{N_1}, \frac{m}{N_1}], \\ 0 & x \in \mathbb{R} \setminus [-\frac{m}{N_1}, \frac{m}{N_1}] \end{cases} \quad \text{(31)}$$

**Theorem 5** Let $N \in 2\mathbb{N}$ and $\sigma > \frac{\pi}{3}$, where $N_1 = \sigma N \in 2\mathbb{N}$. Further let $m \in \mathbb{N} \setminus \{1\}$ and $\beta = 3m$ be given.
Then the $C(\mathbb{T})$-error constant of the algebraic window function (31) can be estimated by

\[ e_\sigma(\varphi_{\text{alg}}) \leq \frac{3\sqrt{\sigma}}{\sqrt{\pi m} J_{3m}\left(\frac{\pi m}{\sigma}\right)} \left[ 1 + \frac{2\sigma - 1}{(6m - 1)\sigma} \right] (2\sigma - 1)^{-3m - 1/2}, \] (32)

i.e., the algebraic window function (31) is convenient for NFFT.

**Proof** We apply Theorem 2 and introduce the unscaled algebraic window function

\[ \varphi_{0,\text{alg}}(x) := \begin{cases} 
(1 - x^2)^{\beta - 1/2} & x \in [-1, 1], \\
0 & x \in \mathbb{R} \setminus [-1, 1].
\end{cases} \]

Using [16, p. 8], we determine the corresponding Fourier transform

\[ \hat{\varphi}_{0,\text{alg}}(v) = \int_{-1}^{1} (1 - x^2)^{\beta - 1/2} e^{-2\pi i v x} \, dx = 2 \int_{0}^{1} (1 - x^2)^{\beta - 1/2} \cos(2\pi v x) \, dx \]

\[ = \frac{\pi (2\beta)!}{4^\beta \beta!} \begin{cases} 
(\pi v)^{-\beta} J_\beta(2\pi v) & v \in \mathbb{R} \setminus \{0\}, \\
1 & v = 0.
\end{cases} \] (33)

Thus \( \hat{\varphi}_{0,\text{alg}}(v) \) for \( v > 0 \) is a multiple of the function \( (\pi v)^{-\beta} J_\beta(2\pi v) \) which can be represented as infinite product

\[ \frac{1}{\beta!} \prod_{s=1}^{\infty} \left( 1 - \frac{(2\pi v)^2}{j_{\beta,s}^2} \right), \] (34)

where \( j_{\beta,s} \) denotes the \( s \)-th positive zero of \( J_\beta \) (see [1, p. 370]). Note that

\[ j_{6,1} = 9.936109 \ldots, \quad j_{9,1} = 13.354300 \ldots, \quad j_{12,1} = 16.698249 \ldots, \]
\[ j_{15,1} = 19.994430 \ldots, \quad j_{18,1} = 23.256776 \ldots, \quad j_{21,1} = 26.493647 \ldots. \]

For \( \beta = 3m \) it holds \( j_{\beta,1} > 3m + \pi - \frac{1}{2} \) (see [10]). Hence by \( \sigma > \frac{\pi}{3} \) we get

\[ \frac{2\pi m}{2\sigma j_{\beta,1}} < \frac{\pi}{3m + \pi - \frac{1}{2}} < \frac{3m}{3m + \pi - \frac{1}{2}} < 1. \]

Thus each factor of the infinite product (34) is positive and decreasing for \( v \in \left[ 0, \frac{m}{2\sigma} \right] \). Hence by (33) and (34), the Fourier transform \( \hat{\varphi}_{0,\text{alg}}(v) \) is positive and decreasing for \( v \in \left[ 0, \frac{m}{2\sigma} \right] \) and it holds

\[ \hat{\varphi}_{0,\text{alg}}\left( \frac{m}{2\sigma} \right) = \frac{(2\beta)! \pi}{4^\beta \beta!} \left( \frac{2\sigma}{\pi m} \right)^{\beta} J_\beta\left( \frac{\pi m}{\sigma} \right). \] (35)
By (17) we know that for $|v| \geq \frac{m}{2}$ it holds
\[ |J_\beta(2\pi v)| \leq \frac{3}{2\sqrt{2\pi}|v|}. \] (36)

For $|v| \geq m \left(1 - \frac{1}{2\sigma}\right)$ and $\sigma > \frac{\pi}{3}$ it holds
\[ |v| \geq m \left(1 - \frac{1}{2\sigma}\right) > \frac{m}{2}. \]

Using (33) and (36), we obtain for $|v| \geq m \left(1 - \frac{1}{2\sigma}\right)$ the estimate
\[ |\hat{\phi}_{0,\text{alg}}(v)| \leq \frac{3}{2^{3/2}4^{\beta}} \beta! \pi^{\beta-1/2} |v|^{-\beta-1/2}. \] (37)

Applying Theorem 2, we obtain
\[ e_\sigma (\varphi) \leq \frac{1}{\hat{\varphi}_0 \left(\frac{m}{2\sigma}\right)} \left[2c_1 + \frac{2c_2}{(\mu - 1) m^\mu \left(1 - \frac{1}{2\sigma}\right)^{1-\mu}}\right], \]

where by (37) we have $\mu = \beta + 1 = 3m + \frac{1}{2}$ and
\[ c_1 = \frac{3}{2^{3/2}4^{\beta}} \beta! \pi^{\beta-1/2} m^{-\beta-1/2} \left(1 - \frac{1}{2\sigma}\right)^{1-\mu}, \]
\[ c_2 = \frac{3}{2^{3/2}4^{\beta}} \beta! \pi^{\beta-1/2}. \]

Using (35), we get the inequality (32). \qed

### 5.4 Bessel window function

Let $N \in 2\mathbb{N}$, $m \in \mathbb{N}\setminus\{1\}$, and $\sigma \in \left[\frac{5}{4}, 2\right]$ be given. For fixed shape parameter
\[ \beta := 2\pi m \left(1 - \frac{1}{2\sigma}\right), \] (38)

we consider the new Bessel window function
\[ \varphi_{\text{Bessel}}(x) := \begin{cases} \frac{1}{I_2(\beta)} \left(1 - \frac{(N_1 x)^2}{m^2}\right) I_2 \left(\beta \sqrt{1 - \frac{(N_1 x)^2}{m^2}}\right) & x \in \left[-\frac{m}{N_1}, \frac{m}{N_1}\right], \\ 0 & x \in \mathbb{R} \setminus \left[-\frac{m}{N_1}, \frac{m}{N_1}\right]. \end{cases} \] (39)

with $N_1 = \sigma N \in 2\mathbb{N}$. Obviously, the Bessel window function is continuously differentiable and compactly supported.
Theorem 6  Let \( N \in 2\mathbb{N}, m \in \mathbb{N} \setminus \{1\}, \) and \( \sigma \in [\frac{5}{4}, 2] \) be given, where \( N_1 = \sigma N \in 2\mathbb{N} \) and \( 2m \ll N_1 \).

Then the \( C(T) \)-error constant of the Bessel window function (39) with the shape parameter (38) can be estimated by

\[
e_\sigma (\varphi_{\text{Bessel}}) \leq (50m^3 + 7)e^{-2\pi m \sqrt{1 - 1/\sigma}},
\]
i.e., the Bessel window function (39) is convenient for NFFT.

Proof  We apply Theorem 2 and introduce the unscaled Bessel window function

\[
\varphi_{0, \text{Bessel}}(x) := \begin{cases} 
\frac{1}{I_2(\beta)} (1 - x^2) I_2(\beta \sqrt{1 - x^2}) & x \in [-1, 1], \\
0 & x \in \mathbb{R} \setminus [-1, 1].
\end{cases}
\]

We determine the even Fourier transform

\[
\hat{\varphi}_{0, \text{Bessel}}(v) = \int_{\mathbb{R}} \varphi_{0, \text{Bessel}}(x) e^{-2\pi i vx} \, dx = \frac{2}{I_2(\beta)} \int_{0}^{1} (1 - x^2) I_2(\beta \sqrt{1 - x^2}) \cos(2\pi vx) \, dx.
\]

By [16, p. 96], this Fourier transform reads as follows

\[
\hat{\varphi}_{0, \text{Bessel}}(v) = \frac{2\beta^2}{I_2(\beta)} \left\{ \begin{array}{ll}
\sqrt{\frac{\pi}{2}} (\beta^2 - 4\pi^2v^2)^{-5/4} I_{5/2}(\sqrt{\beta^2 - 4\pi^2v^2}) & |v| < m \left(1 - \frac{1}{2\sigma}\right), \\
\frac{1}{15} & v = \pm m \left(1 - \frac{1}{2\sigma}\right), \\
\sqrt{\frac{\pi}{2}} (4\pi^2v^2 - \beta^2)^{-5/4} J_{5/2}(\sqrt{4\pi^2v^2 - \beta^2}) & |v| > m \left(1 - \frac{1}{2\sigma}\right).
\end{array} \right.
\]

Introducing the spherical Bessel function (see [1, pp. 437–438])

\[
j_2(x) := \sqrt{\frac{\pi}{2x}} J_{5/2}(x) = \left(\frac{3}{x^3} - \frac{1}{x}\right) \sin x - \frac{3}{x^2} \cos x, \quad x > 0; \quad j_2(0) := 0,
\]

and the modified spherical Bessel function (see [1, p. 443])

\[
i_2(x) := \sqrt{\frac{\pi}{2x}} I_{5/2}(x) = \left(\frac{3}{x^3} + \frac{1}{x}\right) \sinh x - \frac{3}{x^2} \cosh x, \quad x > 0; \quad i_2(0) := 0,
\]

we obtain

\[
\hat{\varphi}_{0, \text{Bessel}}(v) = \frac{2\beta^2}{I_2(\beta)} \left\{ \begin{array}{ll}
(\beta^2 - 4\pi^2v^2)^{-1} i_2(\sqrt{\beta^2 - 4\pi^2v^2}) & |v| < m \left(1 - \frac{1}{2\sigma}\right), \\
\frac{1}{15} & v = \pm m \left(1 - \frac{1}{2\sigma}\right), \\
(4\pi^2v^2 - \beta^2)^{-1} j_2(\sqrt{4\pi^2v^2 - \beta^2}) & |v| > m \left(1 - \frac{1}{2\sigma}\right).
\end{array} \right.
\]
Using the power series expansion of the modified spherical Bessel function $i_2$ (see [1, p. 443]), for $|v| < m \left(1 - \frac{1}{2\sigma}\right)$ we receive

$$(\beta^2 - 4\pi^2 v^2)^{-1} i_2(\sqrt{\beta^2 - 4\pi^2 v^2}) = \sum_{k=0}^{\infty} \frac{1}{2^k k! (2k + 5)!!} (\beta^2 - 4\pi^2 v^2)^k.$$ 

Hence $\hat{\phi}_{0,\text{Bessel}}(v)$ is positive and decreasing for $v \in \left[0, m \left(1 - \frac{1}{2\sigma}\right)\right)$. Since $\frac{m}{2\sigma} < m \left(1 - \frac{1}{2\sigma}\right)$ for $\sigma \geq \frac{5}{4}$, we conclude

$$\hat{\phi}_{0,\text{Bessel}} \left( \frac{m}{2\sigma} \right) = \frac{2}{I_2(\beta)} (1 - \frac{1}{2\sigma})^2 (1 - \frac{1}{\sigma})^{-1} i_2(2\pi m \sqrt{1 - \frac{1}{\sigma}}).$$

For $m \geq 2$ and $\sigma \geq \frac{5}{4}$, we maintain

$$2\pi m \sqrt{1 - \frac{1}{\sigma}} \geq 4\pi \sqrt{1 - \frac{1}{\sigma}} \geq x_0 := \frac{4\pi}{\sqrt{5}}.$$ 

Applying the inequality (19) with $\mu = \frac{5}{2}$, for $x \geq x_0$ we obtain

$$i_2(x) \geq x_0 e^{-x_0} i_2(x_0) x^{-1} e^x > 0.280573 x^{-1} e^x > \frac{1}{4} x^{-1} e^x.$$ 

Hence for $x = 2\pi m \sqrt{1 - \frac{1}{\sigma}}$ it follows that

$$i_2(2\pi m \sqrt{1 - \frac{1}{\sigma}}) > \frac{1}{8\pi m} (1 - \frac{1}{\sigma})^{-1/2} e^{2\pi m \sqrt{1 - 1/\sigma}}.$$ 

Thus we see that

$$\hat{\phi}_{0,\text{Bessel}} \left( \frac{m}{2\sigma} \right) \geq \frac{1}{4\pi m I_2(\beta)} (1 - \frac{1}{2\sigma})^2 (1 - \frac{1}{\sigma})^{-3/2} e^{2\pi m \sqrt{1 - 1/\sigma}}. \quad (42)$$

Now we estimate the Fourier transform $\hat{\phi}_{0,\text{Bessel}}(v)$ for $|v| \geq m \left(1 + \frac{1}{2\sigma}\right)$. Using the assumptions $m \geq 2$ and $\sigma \in \left[\frac{5}{4}, 2\right]$, for $|v| \geq m \left(1 + \frac{1}{2\sigma}\right)$ we get

$$\sqrt{4\pi^2 v^2 - \beta^2} = \sqrt{4\pi^2 v^2 - 4\pi^2 m^2 \left(1 - \frac{1}{2\sigma}\right)^2} \geq 2\pi m \sqrt{\left(1 + \frac{1}{2\sigma}\right)^2 - \left(1 - \frac{1}{2\sigma}\right)^2} = 2\pi m \frac{1}{\sigma} \geq 4\pi \sqrt{\frac{2}{\sigma}} \geq 4\pi > 6.$$ 

By (16), for all $x \geq 6$ it holds

$$|J_{5/2}(x)| < \frac{1}{\sqrt{x}}.$$
Thus for $|v| \geq m \left(1 + \frac{1}{2\sigma}\right)$, we obtain by (40) that

$$|\hat{\varphi}_{0,\text{Bessel}}(v)| \leq \frac{\sqrt{2\pi} \beta^2}{8\pi^{3/2} I_2(\beta)} (v^2 - m^2 (1 - \frac{1}{2\sigma})^2)^{-3/2}.$$  

Since the function $g : \left(m \left(1 + \frac{1}{2\sigma}\right), \infty\right) \to \mathbb{R}$ defined by

$$g(v) := v^3 (v^2 - m^2 (1 - \frac{1}{2\sigma})^2)^{-3/2} = (1 - \frac{m^2}{v^2} (1 - \frac{1}{2\sigma})^2)^{-3/2},$$

is decreasing and bounded from above by

$$g\left(m \left(1 + \frac{1}{2\sigma}\right)\right) = \frac{(2\sigma + 1)^3}{(8\sigma)^{3/2}},$$

we receive for $|v| \geq m \left(1 + \frac{1}{2\sigma}\right)$ the estimate

$$|\hat{\varphi}_{0,\text{Bessel}}(v)| \leq \frac{m^2 (2\sigma + 1)^3}{32\sigma \sqrt{\pi} \sigma I_2(\beta)} \left(1 - \frac{1}{2\sigma}\right)^2 |v|^{-3}.$$  

(43)

Finally we show that for $|v| \geq m \left(1 - \frac{1}{2\sigma}\right)$ it holds

$$|\hat{\varphi}_{0,\text{Bessel}}(v)| \leq \frac{2\beta^2}{15 I_2(\beta)}.$$  

(44)

By (41) we have

$$\hat{\varphi}_{0,\text{Bessel}}\left(\pm m \left(1 - \frac{1}{2\sigma}\right)\right) = \frac{2\beta^2}{15 I_2(\beta)}.$$  

For $|v| > m \left(1 - \frac{1}{2\sigma}\right)$, it holds by (41) that

$$\hat{\varphi}_{0,\text{Bessel}}(v) = \frac{2\beta^2}{I_2(\beta)} \left(4\pi^2 v^2 - \beta^2\right)^{-1} j_2\left(\sqrt{4\pi^2 v^2 - \beta^2}\right).$$

By the definition of the spherical Bessel function $j_2$ it holds for $x > 0$ that

$$|j_2(x)| = \sqrt{\frac{\pi}{2x}} |J_{5/2}(x)|.$$  

Then from [25, p. 49] it follows that for $x > 0$,

$$|J_{5/2}(x)| \leq \frac{1}{\Gamma(7/2)} \left(\frac{x}{2}\right)^{5/2}.$$
with \( \Gamma(7/2) = \frac{15}{8} \sqrt{\pi} \) such that by \( j_2(0) = 0 \) we obtain the inequality

\[
|j_2(x)| \leq \frac{1}{15} x^2, \quad x \geq 0,
\]

and hence (44).

Applying (27) together with (42), (43), and (44), we conclude that

\[
e_{\sigma}(\varphi_{\text{Bessel}}) \leq \left[ \frac{(4\pi)^3}{15} (1 - \frac{1}{\sigma})^{3/2} m^3 + c(\sigma) \right] e^{-2\pi m \sqrt{1 - 1/\sigma}}.
\]

with

\[
c(\sigma) := \sqrt{\pi} (2\sigma + 1)^3 \frac{8}{8\sigma^{3/2}} (1 - \frac{1}{2\sigma})^{-2} (1 - \frac{1}{\sigma})^{3/2}.
\]

For \( \sigma \in \left[ \frac{5}{4}, 2 \right] \), it holds

\[
\frac{(4\pi)^3}{15} (1 - \frac{1}{\sigma})^{3/2} < 50, \quad c(\sigma) < 7.
\]

This completes the proof. \( \Box \)

### 5.5 sinh-type and related window functions

Let \( N \in 2\mathbb{N}, m \in \mathbb{N}\setminus\{1\} \), and \( \sigma \in \left[ \frac{5}{4}, 2 \right] \) be given. For fixed shape parameter \( \beta \) as stated in (38), we consider the new sinh-type window function

\[
\varphi_{\text{sinh}}(x) := \begin{cases} \frac{1}{\sinh \beta} \sinh \left( \beta \sqrt{1 - \frac{(N_1 x)^2}{m^2}} \right) & x \in \left[ -\frac{m}{N_1}, \frac{m}{N_1} \right], \\ 0 & x \in \mathbb{R}\setminus\left[ -\frac{m}{N_1}, \frac{m}{N_1} \right] \end{cases}
\]

with \( N_1 = \sigma N \in 2\mathbb{N} \). This sinh-type window function belongs to \( \Phi_{m,N_1} \). Note that (45) is not piecewise continuously differentiable, since \( \varphi'_{\text{sinh}}\left( -\frac{m}{N_1} + 0 \right) = \infty \) and \( \varphi'_{\text{sinh}}\left( \frac{m}{N_1} - 0 \right) = -\infty \). Note that the sinh-type window function (45) can be computed much faster than the Bessel window function (39).

**Theorem 7** Let \( N \in 2\mathbb{N}, N \geq 8, m \in \mathbb{N}\setminus\{1\} \), and \( \sigma \in \left[ \frac{5}{4}, 2 \right] \) be given, where \( N_1 = \sigma N \in 2\mathbb{N} \) and \( 2m \ll N_1 \). The shape parameter \( \beta \) is given by (38).

Then the \( C(\mathbb{T}) \)-error constant of the sinh-type window function (45) with the shape parameter (38) can be estimated by

\[
e_{\sigma}(\varphi_{\text{sinh}}) \leq (24 m^{3/2} + 3) e^{-2\pi m \sqrt{1 - 1/\sigma}},
\]

i.e., the sinh-type window function (45) is convenient for NFFT.
A proof of Theorem 7 can be found in [21]. The proof based mainly on the knowledge of the analytical Fourier transform. In [21] we consider in addition two related window functions, namely the continuous exp-type window function

$$\varphi_{\text{exp}}(x) := \begin{cases} \frac{1}{e^\beta - 1} \left( e^\beta \sqrt{1 - (N_1 x/m)^2} - 1 \right) & x \in I, \\ 0 & x \in \mathbb{R}\setminus I. \end{cases}$$

as well as the continuous cosh-type window function

$$\varphi_{\text{cosh}}(x) := \begin{cases} \frac{1}{\cosh \beta - 1} \left( \cosh \left( \beta \sqrt{1 - \left( \frac{N_1 x}{m} \right)^2} \right) - 1 \right) & x \in I, \\ 0 & x \in \mathbb{R}\setminus I. \end{cases}$$

The main drawback for the numerical analysis of the exp-type/cosh-type window function is the fact that an explicit Fourier transform of this window function is unknown. Therefore we split the continuous exp-type/cosh-type window function into a sum $\psi + \rho$, where the Fourier transform of the compactly supported function $\psi$ is explicitly known and where the compactly supported function $\rho$ has small magnitude. For details see [21]. Note that $\varphi_{\text{exp}}$ was first suggested in [2,4] and a discontinuous version of $\varphi_{\text{cosh}}$ was suggested in [4, Remark 13].

### 5.6 Modified cosh-type and related window functions

For $\sigma \in \left[ \frac{5}{4}, 2 \right]$ and $m \in \mathbb{N}\setminus\{1\}$, we consider the modified cosh-type window function

$$\varphi_{\text{m}_{\text{cosh}}}(x) := \varphi_{\text{m}_{\text{cosh}}} \left( \frac{N_1 x}{m} \right), \quad x \in \mathbb{R},$$

where it holds

$$\varphi_{\text{m}_{\text{cosh}}}(x) := \begin{cases} \frac{1}{\cosh \beta - 1} \left( \cosh \left( \frac{\beta \sqrt{1 - x^2}}{\sqrt{1 - x^2}} \right) - 1 \right) & x \in (-1, 1), \\ 0 & x \in \mathbb{R}\setminus(-1, 1) \end{cases}$$

with the shape parameter $\beta$ as stated in (38). By [16, p. 6 and p. 38], its Fourier transform reads as follows

$$\begin{align*}
\hat{\varphi}_{\text{m}_{\text{cosh}}}(v) &= \frac{2}{\cosh \beta - 1} \int_0^1 \frac{\cosh \left( \frac{\beta \sqrt{1 - x^2}}{\sqrt{1 - x^2}} - 1 \right)}{\sqrt{1 - x^2}} \cos(2\pi vx) \, dx \\
&= \frac{\pi}{\cosh \beta - 1} \cdot \begin{cases} [I_0(\sqrt{\beta^2 - 4\pi^2 v^2}) - J_0(2\pi v)] & |v| < \frac{\beta}{2\pi}, \\
[1 - J_0(\beta)] & v = \pm \frac{\beta}{2\pi}, \\
[J_0(\sqrt{4\pi^2 v^2 - \beta^2}) - J_0(2\pi v)] & |v| > \frac{\beta}{2\pi}. \end{cases}
\end{align*}$$

© Birkhäuser
Note that the Fourier integral in [16, p. 38, formula 7.57] reads as follows
\[
\int_0^1 \cosh \left( \beta \sqrt{1-x^2} \right) \frac{\cos(2\pi vx)}{\sqrt{1-x^2}} \, dx = \int_0^{\pi/2} \cosh(\beta \cos t) \cos(2\pi v \sin t) \, dt
\]
\[
= \frac{\pi}{2} \cdot \begin{cases} I_0(\sqrt{\beta^2 - 4\pi^2v^2}) & |v| < \frac{\beta}{2\pi}, \\ 1 & v = \pm \frac{\beta}{2\pi}, \\ J_0(\sqrt{4\pi^2v^2 - \beta^2}) & |v| > \frac{\beta}{2\pi}. \end{cases}
\]
Obviously, the unscaled modified cosh-type window function \( \varphi_{0,mcosh} : \mathbb{R} \rightarrow [0, 1] \) with the support \([-1, 1]\) is even and continuous on \(\mathbb{R}\). Further the restricted function \( \varphi_{0,mcosh}|[0, 1] \) is decreasing. Now we prove that the Fourier transform (47) is positive and decreasing in \([0, \frac{\beta}{2\pi}]\). First we remark that by (47) it holds
\[
\hat{\varphi}_{0,mcosh}(0) = \frac{\pi}{\cosh \beta - 1} I_0(\beta) > 0,
\]
\[
\hat{\varphi}_{0,mcosh}(\frac{\beta}{2\pi}) = \frac{2}{\cosh \beta - 1} \left[ 1 - J_0(\beta) \right] > \frac{1}{\cosh \beta - 1} > 0,
\]
since \( J_0(0) = 1 \) and \( |J_0(\beta)| < \frac{1}{2} \) for \( \beta = 2\pi m \left( 1 - \frac{1}{2\pi} \right) \geq \frac{12\pi}{5} \). Using \( J_0'(x) = I_1(x) \) and \( J_0'(x) = -J_1(x) \), from (47) it follows for all \( v \in (0, \frac{\beta}{2\pi}) \) that
\[
\frac{d}{dv} \hat{\varphi}_{0,mcosh}(v) = \frac{\pi}{\cosh \beta - 1} \left[ - \frac{4\pi^2v}{\sqrt{\beta^2 - 4\pi^2v^2}} I_1(\sqrt{\beta^2 - 4\pi^2v^2}) + 2\pi J_1(2\pi v) \right].
\]
Since by Lemma 8 it holds the inequality
\[
\sqrt{\beta^2 - 4\pi^2v^2} J_1(2\pi v) \leq 2\pi v I_1(\sqrt{\beta^2 - 4\pi^2v^2}), \quad v \in \left[0, \frac{\beta}{2\pi}\right],
\]
the Fourier transform (47) is decreasing in \([0, \frac{\beta}{2\pi}]\).

**Lemma 8** Let \( \beta \) be given by (38) with \( m \in \mathbb{N} \setminus \{1\} \) and \( \sigma \in \left[\frac{5}{4}, 2\right] \) such that \( \beta > 2 \). Then for \( x \in [0, \beta] \) it holds
\[
\sqrt{\beta^2 - x^2} J_1(x) \leq x I_1(\sqrt{\beta^2 - x^2}). \tag{48}
\]

**Proof** Obviously, the inequality (48) holds for \( x = 0 \) and \( x = \beta \), since \( J_1(0) = I_1(0) = 0 \). First we prove (48) for \( x \in \left(0, \frac{\beta}{\sqrt{2}}\right)\). By the known power expansions
\[
J_1(x) = \frac{x}{2} \sum_{k=0}^{\infty} \frac{(-1)^k}{4^k k! (k + 1)!} x^{2k},
\]
\[
I_1(x) = \frac{x}{2} \sum_{k=0}^{\infty} \frac{1}{4^k k! (k+1)!} x^{2k},
\]
we obtain for \( x \in \left(0, \frac{\beta}{\sqrt{2}}\right) \) that
\[
\frac{J_1(x)}{x} = \frac{1}{2} \sum_{k=0}^{\infty} \frac{(-1)^k}{4^k k! (k+1)!} x^{2k},
\]
(49)
\[
\frac{I_1(\sqrt{\beta^2 - x^2})}{\sqrt{\beta^2 - x^2}} = \frac{1}{2} \sum_{k=0}^{\infty} \frac{1}{4^k k! (k+1)!} (\beta^2 - x^2)^k.
\]
(50)

Then from \( x^2 \leq \beta^2 - x^2 \) for \( x \in \left(0, \frac{\beta}{\sqrt{2}}\right) \) it follows by (49) and (50) that
\[
\frac{J_1(x)}{x} \leq \frac{I_1(\sqrt{\beta^2 - x^2})}{\sqrt{\beta^2 - x^2}},
\]
i.e., this implies the inequality (48) for \( x \in \left(0, \frac{\beta}{\sqrt{2}}\right) \).

In the case \( x \in \left[\frac{\beta}{\sqrt{2}}, \beta\right) \), we substitute \( y := \sqrt{\beta^2 - x^2} \in \left(0, \frac{\beta}{\sqrt{2}}\right) \). Then we show that
\[
\frac{y}{\sqrt{\beta^2 - y^2}} J_1(\sqrt{\beta^2 - y^2}) \leq I_1(y), \quad y \in \left(0, \frac{\beta}{\sqrt{2}}\right].
\]
This inequality is fulfilled, since by [25, p. 31],
\[
|J_1(\sqrt{\beta^2 - y^2})| \leq \frac{1}{\sqrt{2}}
\]
and hence
\[
\frac{y}{\sqrt{\beta^2 - y^2}} J_1(\sqrt{\beta^2 - y^2}) \leq \frac{y}{\sqrt{2} \sqrt{\beta^2 - y^2}} \leq \frac{y}{\beta} \leq \frac{1}{2} \leq I_1(y),
\]
since it holds \( \beta > 2 \) as well as \( \frac{y}{\beta} \leq I_1(y) \) for \( y \geq 0 \) by \( I_1(0) = 0, I'_1(0) = \frac{1}{2} \) and \( I''_1(y) > 0 \). This completes the proof.

Thus we obtain
\[
\hat{\varphi}_{0,m\text{cosh}} \left( \frac{m}{2\sigma} \right) = \frac{\pi}{\cosh \beta - 1} \left[ I_0(2\pi m \sqrt{1 - \frac{1}{\sigma}}) - J_0(\frac{\pi m}{\sigma}) \right].
\]
From \( m \geq 2 \) and \( \sigma \in \left[ \frac{5}{4}, 2 \right] \) it follows that
\[
2\pi m \sqrt{1 - \frac{1}{\sigma}} \geq 4\pi \sqrt{1 - \frac{1}{\sigma}} \geq \frac{4\pi}{\sqrt{5}}, \quad \frac{\pi m}{\sigma} \geq \pi.
\]
Hence by (18) it holds
\[
\left| J_0 \left( \frac{\pi m}{\sigma} \right) \right| < \frac{1}{2}.
\]
This implies that
\[
\hat{\varphi}_{0,mcosh} \left( \frac{m}{2\sigma} \right) \geq \frac{\pi}{\cosh \beta - 1} \left[ J_0 \left( 2\pi m \sqrt{1 - \frac{1}{\sigma}} \right) - \frac{1}{2} \right].
\]
Further for \( v \in [m(1 - \frac{1}{2\sigma}), m(1 + \frac{1}{2\sigma})] \) we obtain
\[
|\hat{\varphi}_{0,mcosh}(v)| = \frac{\pi}{\cosh \beta - 1} \left| J_0 \left( \sqrt{4\pi^2 v^2 - \beta^2} \right) - J_0(2\pi v) \right| \leq c_1 = \frac{3\pi}{2(\cosh \beta - 1)},
\]
since by [25, p. 31] and (18) it holds
\[
|J_0 \left( \sqrt{4\pi^2 v^2 - \beta^2} \right)| \leq 1, \quad |J_0(2\pi v)| < \frac{1}{2}.
\]
Thus we can use \( c_1 = \frac{3\pi}{2(\cosh \beta - 1)} \) as constant in Theorem 2.

Finally we determine the decay of (47) for \( |v| \geq m \left( 1 + \frac{1}{2\sigma} \right) \). We show that
\[
|\hat{\varphi}_{0,mcosh}(v)| \leq \frac{3\pi m^2}{2(\cosh \beta - 1)} \left( 1 - \frac{1}{2\sigma} \right)^2 v^{-2}.
\]
(51)

By (47) we know that
\[
|\hat{\varphi}_{0,mcosh}(v)| = \frac{\pi}{\cosh \beta - 1} \left| J_0 \left( 2\pi v \sqrt{1 - \frac{\beta^2}{4\pi^2 v^2}} \right) - J_0(2\pi v) \right|.
\]
Using the power expansion of the Bessel function \( J_0 \), we obtain
\[
J_0 \left( 2\pi v \sqrt{1 - \frac{\beta^2}{4\pi^2 v^2}} \right) - J_0(2\pi v) = \sum_{k=1}^{\infty} \frac{(-1)^k (\pi v)^{2k}}{(k!)^2} \left[ \left( 1 - \frac{\beta^2}{4\pi^2 v^2} \right)^k - 1 \right].
\]
Since for \( k \in \mathbb{N} \) it holds
\[
0 \leq 1 - \left( 1 - \frac{\beta^2}{4\pi^2 v^2} \right)^k \leq 1 - \left( 1 - \frac{\beta^2}{4\pi^2 v^2} \right) = \frac{\beta^2}{4\pi^2 v^2},
\]

\( \copyright \) Birkhäuser
we estimate

\[ |J_0(2\pi v \sqrt{1 - \frac{\beta^2}{4\pi^2 v^2}}) - J_0(2\pi v)| \leq |J_0(2\pi v) - 1| \frac{\beta^2}{4\pi^2 v^2}. \]

Since by (18) it holds \(|J_0(2\pi v)| < \frac{1}{2}\) for \(|v| \geq m \left(1 + \frac{1}{2\sigma}\right)\), we receive the inequality (51). Thus

\[ c_2 = \frac{3\pi m^2}{2 (\cosh \beta - 1)} \left(1 - \frac{1}{2\sigma}\right)^2, \quad \mu = 2 \]

are the corresponding constants of Theorem 2.

For the modified cosh-type window function (46), we estimate the \(C(\mathbb{T})\)-error constant \(e_\sigma(\varphi_{m\cosh})\).

**Theorem 8** Let \(\sigma \in \left[\frac{5}{4}, 2\right]\), \(m \in \mathbb{N} \setminus \{1\}\), and \(N_1 = \sigma_1 N \in 2\mathbb{N} \) with \(2m \ll N_1\).

Then the \(C(\mathbb{T})\)-error constant \(e_\sigma(\varphi_{m\cosh})\) has the upper bound

\[ e_\sigma(\varphi_{m\cosh}) \leq \frac{21}{4} \left[ I_0(2\pi m \sqrt{1 - \frac{1}{\sigma}}) - \frac{1}{2} \right]^{-1}. \] (52)

**Proof** From Theorem 2 with \(\mu = 2\) it follows that

\[ e_\sigma(\varphi_{m\cosh}) \leq \frac{1}{\hat{\varphi}_{0, m\cosh}(\frac{m}{2\sigma})} \left[ 2c_1 + \frac{2c_2}{m^2} \left(1 - \frac{1}{2\sigma}\right)^{-1} \right]. \]

Since

\[ \hat{\varphi}_{0, m\cosh}(\frac{m}{2\sigma}) \geq \frac{\pi}{\cosh \beta - 1} \left[ I_0(2\pi m \sqrt{1 - \frac{1}{\sigma}}) - \frac{1}{2} \right] \]

and

\[ c_1 = \frac{3\pi}{2 (\cosh \beta - 1)}, \quad c_2 = \frac{3\pi m^2}{2 (\cosh \beta - 1)} \left(1 - \frac{1}{2\sigma}\right)^2, \]

we obtain the estimate (52), since by \(\sigma \in \left[\frac{5}{4}, 2\right]\) it holds

\[ 3 + 3 \left(1 - \frac{1}{2\sigma}\right) \leq \frac{21}{4}. \]

By [26] the modified Bessel function \(I_0(x)\) fulfills the inequalities

\[ \frac{e^x}{1 + 2x} < I_0(x) < \frac{e^x}{\sqrt{1 + 2x}}, \quad x > 0. \]
If we apply this result, then we obtain

\[ e_\sigma(\varphi_{\text{mcosh}}) \leq \frac{21}{4} \left( 1 + 4\pi m \sqrt{1 - \frac{1}{\sigma}} \right) \left[ e^{2\pi m \sqrt{1 - 1/\sigma}} - \frac{1}{2} - 2\pi m \sqrt{1 - \frac{1}{\sigma}} \right]^{-1}. \]

This completes the proof. \( \square \)

Finally in our numerical examples, we consider also the modified exp-type window function

\[ \varphi_{\text{mexp}}(x) := \varphi_{0,\text{mexp}} \left( \frac{N_1 x}{m} \right), \quad x \in \mathbb{R}, \]

where it holds

\[ \varphi_{0,\text{mexp}}(x) := \begin{cases} \frac{1}{\exp \beta - 1} \frac{\exp \left( \beta \sqrt{1 - x^2} \right) - 1}{\sqrt{1 - x^2}} & x \in (-1, 1), \\ 0 & x \in \mathbb{R} \setminus (-1, 1) \end{cases} \]

and the modified sinh-type window function

\[ \varphi_{\text{msinh}}(x) := \varphi_{0,\text{msinh}} \left( \frac{N_1 x}{m} \right), \quad x \in \mathbb{R}, \]

where it holds

\[ \varphi_{0,\text{msinh}}(x) := \begin{cases} \frac{1}{\sinh \beta} \frac{\sinh \left( \beta \sqrt{1 - x^2} \right)}{\sqrt{1 - x^2}} & x \in (-1, 1), \\ 0 & x \in \mathbb{R} \setminus (-1, 1). \end{cases} \]

Note that the main idea to consider these modified window functions, comes from the Fourier transform of the Kaiser–Bessel window function, see [19, Remark 1]. The modified sinh-type window function \( \varphi_{\text{msinh}} \) is used in the NFFT package [11], and gives very good error bounds.

**Conclusion**

In this paper, we present explicit error estimates for the NFFT with continuous, compactly supported window function \( \varphi \in \Phi_{m,N_1} \). Such window functions simplify the algorithm for NFFT, since the truncation error of the NFFT vanishes. Using the \( C(\mathbb{T}) \)-error constant of \( \varphi \), we propose a unified approach to error estimates of the NFFT with nonequispaced spatial data and equispaced frequencies as well as of the NFFT with nonequispaced frequencies and equispaced spatial data. Further we discuss the connection with a modified Paley–Wiener theorem.

We present two techniques to find upper bounds of the \( C(\mathbb{T}) \)-error constant. The second method which uses the scaling structure of the window function \( \varphi \), shows that the constant \( e_{\sigma,N}(\varphi) \) is bounded for all \( N \in 2\mathbb{N} \). We see that \( e_{\sigma}(\varphi) \) depends...
The constants $e_{\sigma, 1024}(\varphi)$ of the different window functions with shape parameter $\beta = \pi m(2 - 1/\sigma)$ for $\sigma \in \{1.25, 1.5, 2\}$ and $m \in \{2, 3, 4, 5, 6\}$

Fig. 1 The constants $e_{\sigma, 1024}(\varphi)$ of the different window functions with shape parameter $\beta = \pi m(2 - 1/\sigma)$ for $\sigma \in \{1.25, 1.5, 2\}$ and $m \in \{2, 3, 4, 5, 6\}$ as well as the upper bounds of the $C(\mathbb{T})$-error constants $e_\sigma(\varphi)$ essentially on the decay of the Fourier transform $\hat{\varphi}(v)$ for $|v| \to \infty$ and the positive size of $\hat{\varphi}(v)$ for small frequencies. For the (modified) B-spline, algebraic, Bessel, sinh-type, and modified cosh-type window functions, we present new explicit upper bounds of the corresponding $C(\mathbb{T})$-error constants. Here we use the fact that the Fourier transforms of these window functions are explicitly known. It is remarkable that the $C(\mathbb{T})$-error constants of Bessel, sinh-type, and modified cosh-type window function decay exponentially with respect to $m$. Numerical experiments verify the different behavior of the $C(\mathbb{T})$-error constants for these window functions, see Fig. 1. We point out that the modified cosh-type, exp-type, and sinh-type window functions give the best error constants, see Fig. 2. Note that in Fig. 2, the constants $e_{\sigma, 1024}(\varphi)$ for $\varphi \in \{\varphi_{\text{sinh}}, \varphi_{\text{cosh}}, \varphi_{\text{exp}}\}$ are numerically not distinguishable, but not identical. The same is true for $\varphi \in \{\varphi_{\text{msinh}}, \varphi_{\text{mcosh}}, \varphi_{\text{mexp}}\}$. The modified sinh-type window function, see Sect. 5.6, is used in the NFFT package [11].
