ABSTRACT: In the search for QFT’s that admit boundstates, we reinvestigate the two dimensional Gross-Neveu model, but with massive fermions. By computing the self-energy for the auxiliary boundstate field and the effective potential, we show that there are no bound states around the lowest minimum, but there is a meta-stable bound state around the other minimum, a local one. The latter decays by tunneling. We determine the dependence of its lifetime on the fermion mass and coupling constant.

KEYWORDS: spectrum of bound states.
1. Introduction

Bound states are a very important ingredient of physical systems. From hadrons via atoms and molecules and all the way to solar systems and galaxies we encounter in nature systems where a bunch of “elementary objects” are bound together. Whereas, for most of such systems the binding mechanism is well understood, for hadrons the process of confining together quarks and gluons is still quite far from being fully understood. Moreover, QFT in general has been developed to handle mainly amplitudes of scattering and much less tools have been constructed to analyze the phenomena of bound states.

A landmark development en route to deciphering confinement in four dimensional QCD has been ’t Hooft’s solution of two dimensional QCD in the large number of colors $N$ limit [1]. A Bethe-Salpeter equation for the wavefunction of the quark anti-quark bound state was solved and the corresponding spectrum was determined. It is easy to realize that the same “magic” cannot be achieved for QCD in higher, even not three, dimensions. A simpler toy model in three dimensions is the Chern-Simons (CS) theory coupled to fundamental matter. Tremendous progress has been made in recent years in understanding various aspects of these systems. In particular we have shown [2], [3] that unlike the two dimensional QCD case, the three dimensional Chern-Simons theory coupled to fundamental fermions in the large $N$, large level $K$ limits where $\lambda = \frac{N}{K}$ is kept fixed, does not admit a bound state spectrum. This was done by proving that the ’t Hooft like bound state equations do not have solutions. On the other hand in [4] it was shown that the CS theory coupled to scalars in the fundamental representation with quartic self interaction does
admit poles in the scattering amplitude which correspond to particle anti-particle bound states in the singlet channel. Furthermore, it was shown [5] that this theory in the so called “Wilson-Fisher” limit is equivalent to the theory of fundamental fermions coupled to a CS gauge theory. This equivalence holds for a range of parameters that does not include the region where the S matrix has poles so there is no contradiction between the no bound states of [3] and the poles of [4]. These findings raise a natural question of whether the theories of fundamental matter with quartic interaction both for bosons and fermions but with no coupling to the CS gauge fields admit bound states. This question, in various dimensions, is the subject of the current paper and a following one [7].

Unlike the method we have used in [2] and [3], in this paper we use a much simpler method. Following the gross Neveu model [GN] [8], we formulate the quartic interactions by invoking a singlet auxiliary field which trivially upon integrating it out yields the ordinary formulation. We compute (exactly in large N) the self-energy of the auxiliary field, but this time with non-zero fermion mass, and check for what domain of the parameters of the theory it admits poles. It turns out that the effective potential has two minima. There are no bound states around the lower one, while there is one bound state around the other one. This state is unstable. It decays by tunneling to the lower minimum, which is the ground state. Its life time dependence on the mass and the coupling constant is determined. In the limit of infinite coupling this state becomes massless and the binding energy is twice the fermion physical mass. It is worth mentioning that the binding at threshold for the massless case is the leading result in large N, but at finite N it was found out in [9] that

\[
\frac{M_s}{2M_F} = \cos \left( \frac{\pi}{N-2} \right)
\]

so that there is a binding energy at order \(O\left(\frac{1}{N}\right)\) (See also [11] eq 4.27).

The GN model and its generalizations have been thoroughly investigated from various different points of view. For review papers and references therein see [10] in 2+1 dimensions and [11]. The massive GN model has attracted less attention than the massless one, however certain properties of the massive were also examined for instance in [9] [12], where the binding energies for all the antisymmetric tensor multiplets were computed.

The paper is organized as follows. In section §2 we describe three methods of handling bound states in QFT, and in particular we elaborate on the auxiliary field method. In the next section we review the self energy of the auxiliary field. In section §4 we calculate the effective potential, for the case of a massive fermion. We show that for a certain range of the coupling constant the system admits one quasi-stable bound state. In the last section we summarize the results of the various different cases and present some open questions.

2. Probing bound states

Quantum field theories are equipped with efficient tools to study scattering processes, but the toolkit for analyzing bound states is much more limited. Among the methods to address the issue of bound states are:

1. The identification of poles of the S matrix,
2. Solving the bound state wave-function, like ’t Hooft in two dimensions, and

\footnote{The possibility of having a massless bound state was discussed in [6]}
3. Studying the propagator of an auxiliary field, that upon the use of the equations of motion equals to a bound state of two underlying fields.

Let us now elaborate on the latter. Four Fermi interactions like that of the Gross-Neveu model is known to be renormalizable in two space-time dimensions. However in the large $N$ limit such an interaction is renormalizable also in higher dimensions [10]. For the class of models with quartic interactions of fields, either fermionic or bosonic, one can examine the question of whether the model admits a bound state by examining the propagator of an auxiliary field. The latter is introduced in the following form

$$ L(\Phi, \partial \mu \Phi, \bar{\sigma}) = L_0(\Phi, \partial \mu \Phi) + \frac{1}{2} \mu^2 \bar{\sigma}^2 - g\bar{\sigma} \Phi^\dagger \Phi $$

(2.1)

where $\Phi$ is a field, either bosonic or fermionic, in the fundamental representation of $SU(N)$. The equation of motion of $\bar{\sigma}$ reads

$$ \bar{\sigma} = \frac{g}{\mu^2} \Phi^\dagger \Phi $$

(2.2)

We take now the following limit

$$ g^2 \to \infty \quad \mu^2 \to \infty \quad \frac{g^2}{\mu^2} \equiv \tilde{g}^2 \quad fixed $$

(2.3)

In fact taking the limit of $\mu^2 \to \infty$ is needed if one adds a kinetic term for $\bar{\sigma}$. Using the equation of motion of $\bar{\sigma}$ we obviously get a quartic interaction in the action

$$ L(\Phi, \partial \mu \Phi) = L_0(\Phi, \partial \mu \Phi) - \frac{1}{2} \tilde{g}^2 (\Phi^\dagger \Phi)^2 $$

(2.4)

Note that this emerged from a field $\bar{\sigma}$ that is actually a proper limit of an infinite mass tachyon field. This is important for the scalar case, to ensure positivity of the energy.

The tree level and full propagators of the auxiliary field $\bar{\sigma}$ are

$$ D^{0\Phi}_\bar{\sigma}(k) = i \quad D_\bar{\sigma}(k) = \frac{i}{1 - i\Pi(k)} $$

(2.5)

where $\Pi(k)$ is the self energy of the auxiliary field. From the outcome of the equation of motion (2.2) it follows that $\bar{\sigma}$ is the field that describes a boundstate of $\Phi^\dagger \Phi$. Thus, a boundstate exists if

$D_\bar{\sigma}(k)$ has a pole in the domain of $4M_\Phi^2 > k^2 > 0$.

where $M_\Phi$ is the physical mass of the particle created by the field $\Phi$. If on the other hand

There is a pole in the domain ($-k^2 > 0$), then the theory suffers from a Landau pole.

3. The self energy of $\sigma$

We start with the Lagrangian density

$$ \mathcal{L} = \bar{\psi}(i \gamma^\mu \partial_\mu - m)\psi - \frac{1}{2} \sigma^2 - g\sigma \bar{\psi} \psi $$

(3.1)
where $\psi$ is 2d Dirac fermion in the fundamental representation of $U(N)$ and $\sigma$ is a scalar which is a $U(N)$ singlet. The $\gamma$ matrices in 2d can be expressed in terms Pauli matrices $\gamma_0 = \sigma_1, \gamma_1 = i\sigma_2$. Note that this model differs from the original GN model by the fact that here the fermions are massive. Since $\sigma$ does not have a dynamical term its free propagator is a constant

$$D_\sigma^0(k) = -i$$

(3.2)

The fermion free propagator is given by

$$S_\psi^0(k) = \frac{i}{k - m}$$

(3.3)

Next we proceed to compute the scalar self energy. We do it in the large $N$ limit for which

$$N \to \infty \quad g^2 N \equiv \lambda \text{ fixed}$$

(3.4)

where $\lambda$ is dimensionless. The full propagator of $\sigma$ is given by

$$D_\sigma(k) = \frac{-i}{1 + i\Pi(k)}$$

(3.5)

where

$$\Pi(k) = \lambda \int \frac{d^2 q}{(2\pi)^2} \text{Tr} \left[ \frac{i}{[\gamma^\mu q_\mu - m]} \frac{i}{[\gamma^\nu (q-k)_\nu - m]} \right]$$

$$= -\lambda \int \frac{d^2 q}{(2\pi)^2} \frac{2(q^2 - k \cdot q + m^2)}{(q^2 - m^2)(k-q)^2 - m^2}$$

(3.6)

Note that in the large $N$ limit, the full result is given by the one loop contribution.

The full propagator in 3.5 is different than in 2.5, since in the latter we had a tachyonic $\sigma$.

As is common we introduce a Feynmann variable $\alpha$ so that

$$\Pi(k) = -2\lambda \int_0^1 d\alpha \int \frac{d^2 q}{(2\pi)^2} \frac{q^2 - k \cdot q + m^2}{[q^2 + \alpha k^2 - m^2 - 2ak \cdot q]^2}$$

$$= -2\lambda \int_0^1 d\alpha \int \frac{d^2 q}{(2\pi)^2} \frac{(q + ak)^2 - (\alpha k + q) \cdot k + m^2}{[q^2 + \alpha(1-\alpha)k^2 - m^2]^2}$$

$$= -2\lambda \int_0^1 d\alpha \int \frac{d^2 q}{(2\pi)^2} \frac{q^2 + m^2 - \alpha(1-\alpha)k^2}{[q^2 + \alpha(1-\alpha)k^2 - m^2]^2}$$

$$= 2i\lambda \int_0^1 d\alpha \int \frac{d^2 q_E}{(2\pi)^2} \frac{q^2_E - m^2 - \alpha(1-\alpha)k^2}{[q^2_E + m^2 - \alpha(1-\alpha)k^2]^2}$$

(3.7)
Incorporating now a dimensional regularization with $D = 2 - 2\epsilon$ we get

\[
\Pi(k^2) = \frac{i\lambda}{2\pi} \int_0^1 d\alpha \left[ \frac{1}{m^2} [m^2 - \alpha(1 - \alpha)k^2] \right]^{-\epsilon} \int_0^\infty \xi^{1-2\epsilon} d\xi \frac{\xi^2 - 1}{(\xi^2 + 1)^2} \\
= \frac{i\lambda}{2\pi} \int_0^1 d\alpha \left[ \frac{1}{m^2} [m^2 - \alpha(1 - \alpha)k^2] \right]^{-\epsilon} \left[ \frac{1}{\epsilon} - 1 + O(\epsilon) \right] \\
= \frac{i\lambda}{2\pi} \left[ \frac{1}{\epsilon} - 1 \right] - \frac{i\lambda}{2\pi} \int_0^1 d\alpha \ln \left[ \frac{1}{m^2} [m^2 - \alpha(1 - \alpha)k^2] \right] 
\]

(3.8)

Define now the renormalized coupling

\[
G^2_R = \frac{\lambda}{1 - \frac{\lambda}{2\pi} \left( \frac{1}{\epsilon} - 1 \right)} 
\]

(3.9)

A pole in the propagator appears when

\[
1 + \frac{G^2_R}{2\pi} \int_0^1 d\alpha \ln \left[ \frac{1}{m^2} [m^2 - \alpha(1 - \alpha)k^2] \right] = 0 
\]

(3.10)

In fact as will be shown below the condition for the pole is determined by this equation when we replace

\[
m \to M_F = m + g\sigma_m
\]

where $\sigma_m$ is the minimum of the effective potential.

The requirement of no Landau pole is obeyed for

\[
\frac{G^2_R}{\pi} \geq 1
\]

(3.11)

The system admits one bound state. Note that in this case the self-energy vanishes at $k^2 = 0$, so no subtraction needed.

Of course to get the full effects, we need to compute the $\sigma$ potential, as was done by Gross-Neveu [8], but with a finite mass $m$ this time.

We have used dimensional regularization here, as will be more convenient in higher dimensions. However in the next section we will use the subtraction method, like in the GN paper.

4. The effective potential

Due to translational invariance the vacuum expectation value of the field $\sigma(x)$ has to be $x^\mu$ independent, namely a constant. We denote it by $\sigma_c = \langle 0 | \sigma | 0 \rangle$. The generating functional is given by

\[
\Gamma(\sigma_c) = \int d^Dx V(\sigma_c) 
\]

(4.1)
$V(\sigma_c)$ is the effective potential. Since $\Gamma$ is the generating functional of the one particle irreducible (1PI) $n$ point function the effective potential is thus

$$V(\sigma_c) = \sum_n \frac{1}{n!} (\sigma_c)^n \Gamma_n(0,0,\ldots,0) \quad (4.2)$$

where $\Gamma_n(0,0,\ldots,0)$ is the sum of all the 1PI Green’s function with $n$ external lines of $\sigma$ at zero momentum. At tree level it is obvious that $V(\sigma_c) = \frac{1}{2}(\sigma_c)^2$. To leading order in $\frac{1}{N}$ we have to sum all the one loop graphs with a UV cutoff $\Lambda$. Therefore the effective potential is

$$V(\sigma_c) = \frac{1}{2}(\sigma_c)^2 - iN \int \frac{d^Dk}{(2\pi)^D} Tr \left( \frac{1}{k-m} \right)^n \quad (4.3)$$

Performing the infinite sum we get

$$V(\sigma_c) = \frac{1}{2}(\sigma_c)^2 + iN \int \frac{d^Dk}{(2\pi)^D} Tr \left( \frac{1}{2} \ln(1 - \frac{(g\sigma_c + m)^2 - m^2}{k^2 - m^2}) - \frac{2mg\sigma_c}{k^2 - m^2} \right) \quad (4.4)$$

We can now make a change of variables $k^\mu \to -k^\mu$. We then take a half the sum of the original and modified integrals to get

$$V(\sigma_c) = \frac{1}{2}(\sigma_c)^2 + iN \int \frac{d^Dk}{(2\pi)^D} Tr \left( \frac{1}{2} \ln(1 - \frac{(g\sigma_c + m)^2 - m^2}{k^2 - m^2}) - \frac{2mg\sigma_c}{k^2 - m^2} \right) \quad (4.5)$$

The Tr would give a factor of $2 \lfloor \frac{D-1}{2} \rfloor$, where $\lfloor \frac{D}{2} \rfloor$ is the integer part of $\frac{D}{2}$. Going to Euclidean space, and integrating over the angles of the D dimensional sphere we get

$$V(\sigma_c) = \frac{1}{2}(\sigma_c)^2 - K(D) \int_0^\infty x^{D-1} dx \ln(1 + \frac{(g\sigma_c + m)^2 - m^2}{x^2 + m^2}) - \frac{2mg\sigma_c}{x^2 + m^2} \quad (4.6)$$

where $K(D) = \frac{N}{(2\pi)^{\frac{D}{2}}} \Gamma(\frac{D}{2})$, with $C = 1$ for even $D$ and $C = \sqrt{2}$ for odd $D$. The area of the unit sphere in D dimensions, namely $\frac{2\pi^{\frac{D}{2}}}{\Gamma(\frac{D}{2})}$, was used.

We can evaluate the integral in general $D$ dimensions. The explicit expression is lengthy, and will be given elsewhere.

For $D=2$ and after introducing a cutoff $\Lambda$ the effective potential reads

$$V(\sigma_c) = \frac{1}{2}(\sigma_c)^2 - \frac{N}{4\pi} \left[ (g\sigma_c)^2 \ln \frac{\Lambda^2}{m^2} - (g\sigma_c + m)^2 \ln \frac{(g\sigma_c + m)^2}{m^2} + (g\sigma_c + m)^2 - m^2 \right] \quad (4.7)$$

Due to the divergence, renormalize by subtracting

$$V(\sigma_c) \to V(\sigma_c) - \frac{1}{2} C_R(\sigma_c)^2$$

Following [8] we now that

$$\frac{\partial^2 V}{\partial \sigma_c^2} |_{\sigma_c = \sigma_0} = 1 \quad (4.8)$$

This leads to the relation

$$C_R = -\frac{\lambda}{2\pi} \left[ \ln \frac{\Lambda^2}{m^2} - \ln \frac{(\sigma_0 + m)^2}{m^2} - 2 \right]$$
From which one gets, for the subtracted potential
\[ V(\sigma_c) = \frac{1}{2} \frac{\sigma_c^2}{4\pi} + \frac{N}{4\pi} \left[ (g\sigma_c + m)^2 \ln \left( \frac{(g\sigma_c + m)^2}{m^2} \right) + (m^2 + 2mg\sigma_c) \ln \left( \frac{(g\sigma_c + m)^2}{m^2} \right) - 3(g\sigma_c)^2 - 2mg\sigma_c \right] \] (4.9)

The derivative of the potential is
\[ V'(\sigma_c) = \sigma_c + \frac{Ng}{2\pi} \left[ g\sigma_c \ln \left( \frac{(g\sigma_c + m)^2}{m^2} \right) + m \ln \left( \frac{(g\sigma_c + m)^2}{m^2} \right) - 2g\sigma_c \right] \] (4.10)

We want to find the minimum of the potential. For the case of \( m = 0 \) the result agrees with [8], of course. For that case the minimum of the potential is at
\[ \sigma_m = \sigma_0 e^{(1 - \frac{\rho}{\pi})} \] (4.11)

and the mass of the fermion is \( m_F = g\sigma_m \). For \( m \neq 0 \) there is no analytic solution for the minimum \( \sigma_m \). However one can find its approximated value numerically. For instance for the case that \( \epsilon = \frac{m}{g\sigma_0} << 1 \) we get that \( \sigma_m \) will have, besides \( e^{(1 - \frac{\rho}{\pi})} \), extra terms of \( \epsilon \ln \epsilon \) and \( \epsilon \), which can be computed directly from \( V'(\sigma_m) = 0 \).

We can rewrite (4.9) as
\[ V(\sigma_c) = \frac{1}{2} \frac{\sigma_c^2}{4\pi} + \frac{N}{4\pi} \left[ (g\sigma_c + m)^2 \ln \left( \frac{(g\sigma_c + m)^2}{m^2} \right) + 2(g\sigma_c)^2 \ln \rho - 3(g\sigma_c)^2 - 2mg\sigma_c \right] \] (4.12)

where \( \rho = \frac{m}{g\sigma_0 + m} \). We now choose the scheme where \( V'(\sigma_0) = 0 \), in which case the coupling can be eliminated as
\[ \frac{\lambda}{\pi} = \frac{(1 - \rho)}{[(1 - \rho) + \rho \ln \rho]} \]

Defining \( x \equiv \frac{g\sigma_c}{m} \) and \( y \equiv \frac{V g^2}{m^2} \) the potential now takes the form
\[ y = \frac{1}{2} x^2 + \frac{(1 - \rho)}{4[(1 - \rho) + \rho \ln \rho]} \left[ (x + 1)^2 \ln ((x + 1)^2) + 2x^2 \ln \rho - 3x^2 - 2x \right] \] (4.13)

In figure 1 we draw \( y \) as a function of \( x \). The first and second derivatives now read
\[ y' = x + \frac{(1 - \rho)}{[(1 - \rho) + \rho \ln \rho]} \left[ (x + 1) \ln ((x + 1)) + x \ln \rho - x \right] \] (4.14)
\[ y'' = 1 + \frac{(1 - \rho)}{[(1 - \rho) + \rho \ln \rho]} \left[ \ln ((x + 1)) + \ln \rho \right] \] (4.15)

We can now check that the point \( \sigma_0 \) where the renormalization condition (4.8) \( y'' = 1 \) is obeyed occurs at \( x = \frac{1}{\rho} - 1 \). At this point \( y' = 0 \), as chosen. This is one of the two local minima of the potential (see figure 1). It fact this is the “false” vacuum point that occurs for a positive value of \( x \). At \( x = 0 \) there is another extremum point since \( y'(x = 0) = 0 \) but that is a maximum point. Since \( y \to \infty \) when \( x \to -\infty \) it implies that there is another minimum for negative value of \( x \). As can be seen in figure 1 this is the “true minimum”. This minimum obviously determines the fermion mass
\[ M_F = g\sigma_m + m = m(x_m + 1) \] (4.16)
It is easy to see that $M_F < 0$ since for $x = -1$ $y' > 0$. At the true minimum the second derivative of the potential is

$$V''(\sigma_m) = 1 + \frac{\lambda}{2\pi} \ln \left( \frac{(g\sigma_m + m)^2}{(g\sigma_0 + m)^2} \right)$$

$$= \frac{\lambda}{\pi} \left[ 1 - \frac{m}{M_F - m} \ln(\frac{M_F}{m}) \right]$$

(4.17)

Where we also used the fact that the first derivative vanishes at $x_m$.

![Figure 1: $Vg^2_{\text{eff}}$ as a function of $\frac{\sigma}{m}$ for $\rho = 0.1$](image)

**5. Bound states**

To examine the question of whether the system admits bound-states we now go back to (3.6) the equation for $\Pi(k^2)$. First we renomialze the logarithmic divergent expression by by subtraction at $k^2 = 0$, namely we get $\hat{\Pi}(k^2) \equiv \Pi(k^2) - \Pi(k^2 = 0)$

$$\hat{\Pi}(k^2) = -\frac{i\lambda}{2\pi} \int_0^1 d\alpha \ln \left[ 1 - \alpha(1 - \alpha) \frac{k^2}{m^2} \right]$$

(5.1)

A bound state exists if there is a pole in the $\sigma$ propagator. The condition for the latter is

$$\left. \frac{\partial^2 V}{\partial \sigma_i^2} \right|_{\sigma_i = \sigma_m} + \frac{\lambda}{2\pi} \int_0^1 d\alpha \ln \left[ 1 - \alpha(1 - \alpha) \frac{k^2}{M_F^2} \right] = 0$$

(5.2)

Following the structure of the minima of the effective potential we now discuss separately the false vacuum denoted by $\sigma_{fm}$ and the true vacuum $\sigma_{tm}$.
5.1 Meta-stable bound state

For the false vacuum we showed that \( \frac{\partial^2 V}{\partial \sigma^2} \big|_{\sigma = \sigma_{fm}} = 1 \) and hence the condition for having a “meta stable bound state” is

\[
1 + \frac{\lambda}{2\pi} \int_0^1 d\alpha \ln \left[ 1 - \alpha(1 - \alpha) \frac{k^2}{M_F^2} \right] = 0 \quad (5.3)
\]

Performing the integral the condition takes the form

\[
\sqrt{\frac{4M_F^2}{k^2} - 1} \arctan \left[ \frac{1}{\sqrt{\frac{4M_F^2}{k^2} - 1}} \right] = 1 - \frac{\pi}{\lambda} \quad (5.4)
\]

We use now the physical mass \( M_F \), as obtained from the effective potential calculated above. We also show there, that \( \lambda \) is determined by the ratio \( \rho = \frac{m}{M_F} \), and that for \( 1 > \rho > 0 \) we have \( \frac{\lambda}{\pi} > 1 \). Thus in this region there is one bound state. It is close to the threshold for small \( \rho \), and gets closer to zero mass when \( \rho \) gets close to one from below.

We can also define the following dimensionless measure of the binding energy

\[
\eta \equiv \frac{4M_F^2 - k^2}{4M_F^2} \quad (5.5)
\]

From the condition (5.4) we find that binding at threshold \( \eta = 0 \) occurs for \( \frac{\lambda}{\pi} = 1 \) and the maximal binding \( \eta = 1 \) for \( \frac{\lambda}{\pi} \to \infty \).

In figure 2 we plot the binding energy parameter \( \eta \) as a function of \( \frac{\lambda}{\pi} \).

![Binding energy parameter graph](image)

**Figure 2**: The binding energy parameter \( \eta \) as a function of the coupling \( \lambda \)

Next we would like to determine the decay width of the meta-stable state, We follow here the approach of [15], [16] about the decay of the false vacuum (see also discussion below).

\footnote{The fact that this paper was withdrawn by the author is not relevant for our purposes since the problem was with the assumption that the bounce of minimum action is spherically symmetric, and we deal with a two dimensional case}
The decay width per unit length for this two dimensional field theory takes the form

$$\Gamma_L = \frac{B e^{-\frac{2\pi}{\hbar} \left[ \frac{\text{det}'[\partial^2 + V''(\sigma)]}{\text{det}[\partial^2 + V''(\sigma_m)]]} \right]^{-1/2} \times [1 + O(h)]}{\hbar}$$

(5.6)

where \(\text{det}'\) is the determinant without the zero modes, and the constant \(B\) which is in fact the Euclidean action associated with the bounce, is to be computed.

This formula is based on Eq.(3.6) in ref [16], adopted to the two dimensional case. This means that the space volume element is now \(L\), and the factor that appears in front is \(\frac{B}{\hbar}\), as it is the square root of the factor in the four dimensional case.

To compute the decay, we need some approximations.

Following [15], we treat the perturbative case of \(\frac{m g}{\sigma_0} << 1\). So we replace \(V\) by \(\tilde{V}(\sigma)\), the “unperturbed potential”, namely the potential (4.9) for the massless case \(m = 0\) shifted to be zero at the minimum.

We now follow Eq.(4.9) in Ref [15], adopted to the two dimensional case.

The suppression factor \(B\) which for the 4d case was found to be [15] \(B = \frac{27\pi^2 S_1^2}{2\epsilon^3}\) is now given by

$$B = \frac{1}{4} \frac{S_1^2}{\epsilon}$$

(5.7)

\(S_1\) is

$$S_1 = \frac{1}{\sigma_0} \int_{-\sigma_m}^{\sigma_m} d\sigma \sqrt{2\tilde{V}(\sigma)}$$

$$= \frac{1}{\sqrt{2}} \sigma_0 \int_{1}^{1} dz \sqrt{z \ln(z) + 1 - z} \approx 0.30 \sigma_0$$

(5.8)

where we chose the minimum to occur at \(\sigma_0\), and the parameter \(\epsilon\), that “measures” the deviation due to the introduction of the fermionic mass, is defined by approximating the potential as

$$V(\sigma, m) \approx V(\sigma, m = 0) + \frac{\epsilon}{2\sigma_m}(\sigma - \sigma_m)$$

(5.9)

Using the expression of the potential (4.9) we find that

$$\epsilon = 2m \frac{\sigma_0}{g} \ln \left( \frac{g\sigma_0}{m} \right)$$

(5.10)

Substitute this and (5.8) into (5.6) to get

$$B \approx 0.011 \frac{\left( \frac{g\sigma_0}{m} \right)}{\ln \left( \frac{g\sigma_0}{m} \right)}$$

(5.11)

So as \(m \to 0\), \(B\) tends to \(\infty\), thus making the meta-stable state more and more long lived. The other minimum, to leading order in \(m \ln \left( \frac{g\sigma_0}{m} \right)\), is at

$$g\sigma_{tm} = - \left[ g\sigma_0 + 2m \ln \left( \frac{g\sigma_0}{m} \right) \right]$$

(5.12)
Now, as in our case the field $\sigma$ has no kinetic term, the expression for the determinant in (5.6) should be modified. We will not elaborate on that here, as in any case this will modify the overall coefficient, but not change the fact that $B$ tends to $\infty$ as $m \to 0$.

Now to the case of very large $m$ compared to $g\sigma_0$. In this case the potential at false vacuum tends to a finite depth,

$$g^2V(\sigma_0) \approx -\frac{1}{6}(g\sigma_0)^2$$

(5.13)

The true vacuum moves to more negative values,

$$g\sigma_{tm} \approx -4.6m$$

and the potential there gets more deep,

$$g^2V(\sigma_{tm}) \approx -10.53m^2\left(\frac{m}{g\sigma_0}\right)$$

(5.14)

The decay of the meta-stable bound state will be slow also in this case, as the depth of the false vacuum tends to a constant, while the width of the barrier grows. Alas, we do not compute it here.

5.2 No stable bound states

Next we discuss the condition of having a bound state for the system at the true vacuum $\sigma_{tm} < 0$. For this case we use the expression found in (4.17) for the second derivative of the potential and get that the condition for having a pole reads

$$\frac{\lambda}{\pi} \left[ 1 - \frac{m}{M_F - m} \ln\left(\frac{M_F}{m}\right) \right] + \frac{\lambda}{2\pi} \int_0^1 d\alpha \ln\left[ 1 - \alpha(1 - \alpha) \frac{k^2}{M_F^2} \right] = 0$$

(5.15)

Thus we see that the dependence on $\lambda$ cancels out and the condition is

$$\left[ 1 - \frac{m}{M_F - m} \ln\left(\frac{M_F}{m}\right) \right] = \sqrt{\frac{4M_F^2}{k^2} - 1} \arctan\left[ \frac{1}{\sqrt{\frac{4M_F^2}{k^2} - 1}} \right]$$

(5.16)

One can show that the first derivative is positive also for $x=-2$, thus getting that

$$|M_F| > m$$

Now, cancelling the factor $\frac{\lambda}{\pi}$ in (5.15), the second term is negative and between 0 and -1, while the first is positive and larger than 1. Since this condition cannot be fulfilled, there is no stable bound state to the mass deformed GN model.

6. Summary

In this note we address the issue of bound states in the two dimensional Gross Neveu model with massive fermions. In the original paper it was shown that in the large N limit for the massless case there is no binding energy, namely, it is a binding at threshold. For the
massive case the situation is different, as there is, besides the lowest minimum, another 
one, from which states may tunnel, their life time depending of course on the parameters of 
the system.

It is shown that there are no bound states above the lowest minimum, while above the 
other there is one bound state. When the coupling constant is $\lambda = \pi$ the binding energy 
vanishes and when the coupling goes to infinity the binding energy is maximal, namely 
$2M_F$, twice the fermion physical mass, and the bound state is massless.

We would like to mention that in [13] [14], based on the use of a light-cone Tamm- 
Dankoff approximation, it was found that there is no bound state in the massive G.N. 
model$^3$.

This result is part of a larger investigation of quantum field theories in various dimen-
sions [7]. Naturally one would like to investigate in a similar manner the Gross Neveu 
model in three and four dimensions and also the theories with a scalar in the fundamental 
representation of the $SU(N)$ at large $N$.

**Acknowledgements** We would also like to thank Joshua Feinberg, M. Thies and 
especially Moshe Moshe for a very useful correspondence. We would also like to thank Ofer 
Aharony for comments on the manuscript. The work of J.S was partially supported by a 
center of excellence supported by the Israel Science Foundation (grant number 1989/14), by 
the US-Israel bi-national fund (BSF) grant number 2012383, the Germany Israel bi-national 
fund GIF grant number I-244-303.7-2013 and by the “Einstein Center of Theoretical Physics 
” at the Weizmann Institute.
