Abstract
This study aimed to explore the role of miR-146b-3p in acute respiratory distress syndrome in septic mice. Ten mice were randomly selected as normal group (n = 10, without any treatment) and 60 septic mice with acute respiratory distress syndrome were divided into model group (n = 10, without any treatment), negative control (NC) mimic group (n = 10, injected with NC mimic), miR-146b-3p mimic group (n = 10, injected with miR-146b-3p mimic), si-NC group (n = 10, injected with PI3K γ siRNA NC), si-PI3K γ group (n = 10, injected with PI3K γ silencing plasmid), and miR-146b-3p mimic + oe-PI3K γ group (n = 10, injected with miR-146b-3p mimic + PI3K γ overexpression plasmid). We found that miR-146b-3p negatively regulated PI3K γ. Compared with normal group, model mice had decreased expression of miR-146b-3p, increased expressions of PI3K γ, p-AKT, ASC, NLRP3 and Caspase-1 proteins, higher W/D ratio, and more serum IL-1β and IL-18 content (all \( P < 0.05 \)). All indicators in miR-146b-3p mimic group and si-PI3K γ group were significantly improved as compared to model group (all \( P < 0.05 \)). Over-expression of PI3K γ could weaken the treatment effect of miR-146b-3p mimic in model mice. Therefore, up-regulation of miR-146b-3p can inhibit PI3K/AKT signaling pathway to improve acute respiratory distress syndrome in septic mice.

Introduction
Acute respiratory distress syndrome (ARDS) is a non-cardiogenic pulmonary edema caused by the accumulation of extravascular lung water, and it is a major complication of severe sepsis and septic shock (Nystrom 2008). ARDS is characterized by hypoxemia, pulmonary edema, and significant respiratory failure over time, which leads to multiple organ failure and high mortality (up to 60%) (Wang et al. 2017; Annane et al. 2006; Chawla et al. 2016; Park et al. 2017). Lipopolysaccharide (LPS) is the main agent to construct sepsis-induced ARDS model as LPS can activate inflammatory cells to release inflammatory factors, such as interleukin-1β (IL-1β) and interleukin-18 (IL-18) (Qi et al. 2016). NLRP3 inflammasome as a protein complex contains pro-caspase-1 and apoptosis-associated speck-like protein caspase recruitment domain (ASC); active caspase-1 stimulates IL-1β and IL-18, causing the release of these active cytokines (Li et al. 2018a). NLRP3 inflamasome plays a vital role in the pathological process of ARDS.

AKT1 gene, known as protein kinase Bα, is a key member in AKT family. Moreover, AKT is generally recognized as a key factor in PI3K (phosphatidylinositol 3-kinase) /AKT pathway and acts as a crucial role in cell differentiation, proliferation, metabolism, apoptosis, protein synthesis and transcription (Li et al. 2015). Previous studies have indicated that ARDS can be treated by the inhibition of PI3K/AKT signaling pathway (Ji and Wang 2019; Li et al. 2018b; Yanagi et al. 2015; Zheng et al. 2018). ARDS is a complex pathological process, which is regulated by transcription factors as well as microRNA (miRNA). miRNA is a small endogenous non-coding RNA molecule that has approximately 18–24 nucleotides. It usually binds to the target messenger RNA in the 3’ untranslated region to inhibit its post-transcriptional expression (Wang et al. 2015). Several studies have found that multiple miRNAs affect the occurrence of ARDS. For example, miRNA-122 has relations
with the mortality of ARDS and acute liver injury (Rahmel et al. 2018). miRNA-211 inhibits the function of macrophages releasing IL-10 in LPS-induced ARDS rats (Wang et al. 2018). Down-regulation of miRNA-494 alleviates lung injuries in sepsis-related ARDS by regulating NQO1-Nrf2 signaling pathway (Li et al. 2015). miRNA-23a-5p can be used as a potential biomarker for early sepsis induced ARDS (Liu et al. 2016). Among various miRNA, in previous study, miR-146b was identified as a potential biomarker for early sepsis induced ARDS (Yao et al. 2018). Down-regulation of miRNA-494 alleviates lung injuries in sepsis-related ARDS by regulating NQO1-Nrf2 signaling pathway (Li et al. 2015). miRNA-23a-5p can be used as a potential biomarker for early sepsis induced ARDS (Liu et al. 2016). Few studies have suggested its effect on cancer (Huang et al. 2019), but its role in ARDS is still unknown.

In our study, a target relationship between miR-146b-3p and PI3Kγ was found by bioinformatics prediction. Hence, we speculated that miR-146b-3p might repress PI3K/AKT signaling pathway targeted down-regulation of PI3Kγ expression, thus improving ARDS in septic mice.

**Methods**

**Grouping and treating**

Ten of seventy 10-week-old healthy male C57BL/6 mice of clean grade (purchased from the Laboratory Animal Center of Wenzhou Medical University), weighing 25 ± 5 g, were randomly selected as normal group (n = 10). The rest were used to construct septic mice models with ARDS (Sahtetya et al. 2017). Briefly, mice were anesthetized by intraperitoneal administration of 40 mg/kg pentobarbital sodium. Their trachea and right internal jugular vein were then exposed and 50 mL of sterile LPS (Escherichia coli LPS serotype 0111:B4) or phosphate buffered saline (PBS) were dripped into. A total of 3 × 10^7 PFU Ad-omentin or Ad-β-gal was injected into the internal jugular vein of mice 3 days before LPS or PBS administration. All mice in normal group were received PBS and they were survived. 18 mice received LPS died 24 h after administration. Forty two successfully modelled mice were divided into 6 groups: model group (n = 07, without any treatment), negative control (NC) mimic group (n = 07, injected with NC mimic), miR-146b-3p mimic group (n = 07, injected with miR-146b-3p mimic), si-NC group (n = 07, injected with PI3K γ siRNA NC), si-PI3K γ group (n = 07, injected with PI3K γ silencing plasmid), and miR-146b-3p mimic + oe-PI3K γ group (n = 07, injected with miR-146b-3p mimic + PI3K γ overexpression plasmid). We extracted total RNA in the lung tissues from four mice in each group. By using Trizol (Item number 16096020, Thermo Fisher Scientific, New York, USA; Item number B1802, Harbin HaiGene Co. Ltd., China). Taq Man MicroRNA Assays Reverse Transcription Primer (Thermo Scientific, USA) was used to obtain cDNA. SYBR® Premix Ex Taq™II kit (Xingzhi Biotechnology Co. Ltd., China) was used to perform fluorescent quantitative PCR detection. The working solution included 25 µL SYBR® Premix Ex Taq™II (2×), 2 µL PCR forward primer, 2 µL PCR reverse primer, 1 µL ROX Reference Dye (50×), 4 µL DNA templates and 16 µL ddH2O. Primers were shown in Table 1. Fluorescent quantitative PCR was carried out by using ABI Prism®7300 system (Prism®7300, Shanghai Kunke Instrument Equipment Co. Ltd., China). The reaction condition was that 32 cycles of pre-denaturation at 95 °C for 10 min, denaturation at 95 °C for 15 s and annealing at 60 °C for 30 s followed by extending at 72 °C for 1 min. miR-146b-3p took U6 as the internal reference and PI3K γ used GAPDH as the internal reference. 2^−ΔΔCt showed the relative expression level of a target gene.

**Western blot**

We extracted total protein in the lung tissues from four mice in each group by using RIPA lysis buffer containing PMSF (R0010, Solarbio). Protein concentration was determined using BCA kit (Thermo Fisher, USA), and the samples were mixed with loading buffer and heated on the boiling water bath for 10 min. Then, 30 µg of protein samples were added into sample well and electrophoresis was conducted at a constant voltage of 80 V for 2 h. Proteins were transferred to PVDF membrane (ISEQ00010, Millipore, Billerica, MA, USA) at 110 V for 2 h. The membrane was sealed with 5% skimmed milk powder at 4 °C for 2 h and washed once. The membrane was incubated with primary antibodies, rabbit anti-mouse PI3Kγ (ab140307, 1:1,000, Abcam, UK), AKT (ab179463, 1:10,000, Abcam, UK), AKT (phospho S473)
NLRP3 (ab232401, 1:1,000, Abcam, UK), ASC (ab155970, 1:1,000, Abcam, UK), Caspase-1 (ab238979, 1:1,000, Abcam, UK) and GAPDH (ab8226, 1:2,000, Abcam, UK) at 4 °C overnight and washed three times. The membrane was then incubated with horseradish peroxidase-labeled goat anti-rabbit IgG antibody (1:5,000, Beijing Zhongshan Biotechnology Co. Ltd., China) and washed three times. The membrane was developed by ECL fluorescence detection kit (Item Number BB-3501, Ameshame, UK) and exposed by a gel imager. Images were taken using Bio-Rad image analysis system (BIO-RAD, USA) and analyzed using ImageJ software. Relative protein expression = gray value of the corresponding protein band / gray value of GAPDH protein band.

Wet weight/dry weight ratio

The left lungs of three mice in per group were taken out by thoracotomy, and the blood on the lung surface was sucked dry by filter papers. Then wet weight was weighed out. After the left lung was baked in the oven at 80 °C for 48 h to achieve constant weight, the dry weight was weighed out. Wet weight / dry weight (W/D) ratio and lung water content were calculated to reflect the severity of pulmonary edema. W/D ratio of the lung = wet weight of the lung / dry weight of the lung × 100%.

Hematoxylin and eosin (HE) staining

The lung tissue from three mice in each group was routinely fixed, dehydrated, transparentized, embedded and sliced. Slices were transparentized with xylene, dehydrated in gradient alcohol and washed with distilled water for 1 min. Slices were dewaxed routinely and differentiated in 0.5% hydrochloric acid alcohol differentiation solution for 10 s, blued by rinsing with running water for 10 min and stained in eosin solution for 5 min. Slices were dehydrated routinely, transparentized and sealed with neutral gum. Slices were observed under an optical microscope (XP-330, Shanghai Bingyu Optical Instrument Co. Ltd., Shanghai, China).

Table 1 qRT-PCR primer sequence

| Gene      | Forward: 5'-TGAGAACTGAATTCCATAGGCT-3' | Reverse: 5'-GCACTGTGACCCCGAGACAGG-3' |
|-----------|--------------------------------------|--------------------------------------|
| miR-146b-3p |                                      |                                      |
| U6        |                                      |                                      |
| PI3Kγ     | Forward: 5'-GACGAATTCAATTTAACAATTCTGGAAATGGAG-3' | Reverse: 5'-GCAAAGCTCTTTTATGCTGACATTTCTT-3' |
| GAPDH     | Forward: 5'-CCAATGTTGTCGCCGTGGGATCTCT-3' | Reverse: 5'-GTGGAAGTTCGAGGAGACAACC-3' |

ELISA

Blood extracted from the eyeballs of all mice in per group was placed at room temperature first and at 4 °C overnight and centrifuged at 3,500 xg. The supernatant was collected and cryopreserved at -80 °C. Levels of serum IL-1β and IL-18 were detected by referring to the instructions of ELISA detection kits (IL-1β and IL-18 detection kits number: 69-59812, 69-21183, Wuhan MSKBio, China).

Statistical analysis

All data were analyzed by SPSS21.0 statistical software. The measurement data were expressed as mean ± standard deviation. Comparison among groups was performed by one-way analysis of variance, and pairwise comparison of the mean among groups was carried out by Tukey post-hoc test. P < 0.05 indicated a statistically significant difference.

Results

miR-146b-3p targeted the negative regulation of PI3Kγ gene

The bioinformatics prediction website www.targetscan.org (http://www.targetscan.org/vert_72/) predicted that there was a specific binding site of miR-146b-3p and PI3Kγ (Fig. 1a), which was verified by dual-luciferase reporter system assay. The results showed that miR-146b-3p mimic group had lower luciferase activity for co-transfecting with PGL3-PI3Kγ wt compared with NC mimic group (P < 0.05), and there was no significant difference in luciferase activity in cells transfected with PGL3-PI3Kγ mut (P > 0.05). Therefore, miR-146b-3p could target and negatively regulate the expression of PI3K gene (Fig. 1b).
miR-146b-3p, PI3Kγ, AKT, p-AKT expressions in the lung tissue

We detected the expressions of PI3K/AKT signaling pathway in lung tissues in each group to further confirm the regulation relationship between miR-146b-3p and PI3K/AKT signaling pathway (Fig. 2). Compared with normal group, model mice had significantly lower miR-146b-3p expression and higher PI3Kγ expression (both \( P < 0.05 \)). Compared with model mice, mice in miR-146b-3p mimic group and si-PI3Kγ group had significantly lower PI3Kγ and p-AKT protein expressions (both \( P < 0.05 \)). PI3K overexpression could weaken the effects of miR-146b-3p mimic.

Pathological change of mouse lung

Pathological change of mouse lung was detected by HE staining (Fig. 3). Mice in normal group had regular lung structure and no significant pathological injury. Mice in other groups had various degrees of inflammatory cell infiltration in the pulmonary alveoli and mesenchyme, effusion in the cavity, obvious thickening alveolar septum, partial collapsed alveoli, atelectasis, hyaline membrane, and damaged alveoli. Lung injuries in miR-146b-3p mimic group and si-PI3Kγ group were significantly improved than model group, NC mimic group, si-NC group, and miR-146b-3p mimic + oe-PI3Kγ group. PI3K overexpression could weaken the effects of miR-146b-3p mimic.

Wet weight / dry weight ratio of the lung

W/D ratio of the lung was detected to evaluate lung edema (Fig. 4). Compared with normal group, model mice had significantly higher W/D ratio (\( P < 0.05 \)). Compared with model mice, mice in miR-146b-3p mimic group and si-PI3Kγ group had significantly lower W/D ratio (\( P < 0.05 \)). PI3K overexpression could weaken the effects of miR-146b-3p mimic.

Levels of IL-1β and IL-18 in serum

Levels of IL-1β and IL-18 in serum were detected by ELISA (Fig. 5). Levels of IL-1β and IL-18 were significantly higher in other groups than in normal group (both \( P < 0.05 \)). Compared with normal group, model mice had significantly higher levels of IL-1β and IL-18 (both \( P < 0.05 \)). Compared with model mice, mice in miR-146b-3p mimic group and si-PI3Kγ group had significantly lower levels of IL-1β and IL-18 (both \( P < 0.05 \)). PI3K overexpression could weaken the effects of miR-146b-3p mimic.

NLRP3, ASC and Caspase-1 protein expressions of the lung

Compared with normal group, model mice had significantly higher NLRP3, ASC and Caspase-1 protein expressions (all
Compared with model mice, mice in miR-146b-3p mimic group and si-PI3Kγ group had significantly lower NLRP3, ASC and Caspase-1 protein expressions (all $P < 0.05$). PI3K overexpression could weaken the effects of miR-146b-3p mimic.

**Discussion**

Previous studies have reported that miR-146b-3p may be a blood potential biomarker for lung adenocarcinoma (Rani et al. 2013). For example, Sha et al. found that compared with patients with benign pulmonary nodules and healthy people, miR-146b-3p was significantly overexpressed in peripheral blood of patients with non-small cell lung cancer (Sha and Fan 2018). Thus, we speculated that miR-146b-3p may be involved in other lung diseases, such as sepsis-induced ARDS. But no related animal model or clinical researches have been published. In our study, down-regulated miR-146b-3p was found in lung tissues of mice with sepsis-induced ARDS, indicating that miR-146b-3p may participates in the development of ARDS in sepsis mice.
In order to further explore the mechanism of miR-146b-3p affecting ARDS, we used bioinformatic website to predict the possible target of miR-146b-3p and the result was verified by dual-luciferase reporter system assay. Finally, we found that miR-146b-3p could target and negatively regulate PI3K gene expression. Literature revealed the activated PI3K/AKT signaling pathway in ARDS (Li et al. 2018b; Laffey and Matthay 2017). In this study, we also found that inhibition of PI3K/AKT signaling pathway could improve lung injuries caused by ARDS in septic mice. Therefore, we further speculated that miR-146b-3p may play a positive role in sepsis induced ARDS by inhibiting PI3K/AKT signaling pathway.

Mice with ARDS induce lung injury often had severe lung edema and abnormally elevated inflammatory response, increased lung cell apoptosis. Lung edema is a common induction of ARDS, the degree of which can indicate the treatment efficiency (Saitoh et al. 2002). NLR3 inflammasome is a multi-protein complex composed of NLRR3, ASC and the inactive pro-caspase-1, which is an important part of the inflammatory immune response. NLR3 amino terminal pyrin domain binds to ASC and then recruits pro-caspase-1 to form the inflammasome and then activate caspase-1 to promote maturation and secretion of downstream IL-1β and IL-18 (Jiang et al. 2016; Madouri et al. 2015). Li et al. discovered that pirfenidone could inhibit the activation of NLRP3 inflammasome, which may be promising therapeutic strategy for ARDS (Li et al. 2018a, b, c). To further explore the
upstream regulatory mechanism of miR-146b-3p and PI3K/AKT signaling pathway, sepsis model mice were treated with miR-146b-3p mimic, miR-146b-3p inhibitor or PI3Kγ overexpression virus vectors. The results indicated miR-146b-3p inhibited PI3K/AKT signaling pathway by targeting and inhibiting PI3Kγ gene expression, thereby down-regulating the expressions of inflammasome ASC, NLRP3 and Caspase-1 and reducing IL-1β and IL-18 levels in serum, so as to alleviate lung injuries caused by ARDS in septic mice. Moreover, overexpression of PI3K reversed the protection of miR-146b-3p overexpression on lung injury. Our results were also consistent with previous reports on ARDS in septic mice (Afshari et al. 2010; Mittal and Sanyal 2012; Ding et al. 2017; Xie et al. 2019; Pham and Rubenfeld 2017).

However, the association between miR-146b-3p and ARDS in septic mice has not been fully explained to date; the molecular mechanism by which PI3K/AKT signaling pathway regulates inflammasome NLRP3, ASC and Caspase-1 has not been fully explored; the targeted regulatory network of miR-146b-3p in sepsis-induced ARDS mice is still unclear.

In conclusion, miR-146b-3p, by targeting PI3Kγ gene, mediates PI3K signaling pathway to inhibit the recovery of lung injury in model mice. We further clarify the development mechanism of ARDS in septic mice, which lays a theoretical foundation for the clinical treatment of ARDS.
