Key words: polyps, colorectal cancer, aldehyde dehydrogenase 1
Ключові слова: поліпи, колоректальний рак, альдегіддегідрогеназа 1

Abstract. Comparative analysis of aldehyde dehydrogenase 1 expression in polyps and adenocarcinoma of the distal colon. Shyshkin M.A., Khrystenko T.O. Aldehyde dehydrogenase 1 (ALDH1) is one of the most widely used cancer stem cells markers, even though the question of its significance for certain stages of colorectal carcinogenesis is still unclear. The aim of this study was to compare ALDH1 immunohistochemical expression levels in polyps and adenocarcinoma of the distal colon. Histopathological and immunohistochemical studies of biopsies from 40 patients (biopsies of polyps and histologically non-changed mucosa of the distal colon), as well as surgical material of colorectal adenocarcinoma from 30 patients were carried out. It was established that distal colonic polyps are characterized by cytoplasmic expression of ALDH1 with the median of relative area that is equal to 25.63 (18.26; 30.42)% stromal cells and 32.12 (22.13; 30.05)% cancer cells. The area of ALDH1+ cells varies depending on the pTNM stage of the carcinoma, expression of ALDH1 with the medians of the area that are equal to 40.22 (22.54; 47.77)% stromal cells and 32.12 (23.64; 40.28)% cancer cells. Colorectal adenocarcinoma is characterized by cytoplasmic activation. The median of ALDH1+ cancer cells is significantly increasing during the tumor progression from the I to the IV stages that shows increasing in number of stromal cells which are involved in oncogenic signaling pathways. The median of ALDH1+ stromal cells is significantly increasing during the tumor progression from the I to the IV stages that displays increasing number of stromal cells which are involved in oncogenic signaling pathways activation. The median of ALDH1+ stromal cells area in carcinoma, and the median of ALDH1+ epitheliocytes area in polyps is 1.5 times smaller than the median of ALDH1+ cancer cells area.

Reферат. Порівняльний аналіз експресії альдегіддегідрогенази 1 в поліпах і адекарциномі дистальної товстої кишки. Шишкін М.А., Христенко Т.О. Альдегіддегідрогеназа 1 (ALDH1) є одним з найчастіше використовуваних маркерів ракових стовбурових клітин, проте питання щодо його значущості відносно окремих етапів колоректального канцерогенезу лишається до сьогодення невизначеним. Метою цього дослідження стало порівняння рівнів імуногістохімічної експресії ALDH1 в поліпах і адекарциномі дистальної товстої кишки. Проведено патоморфологічне та імуногістохімічне дослідження біопсійного матеріалу 40 пацієнтів (біопсії поліпів і гістологічно незміненої слизової оболонки дистальної товстої кишки), а також операційного матеріалу колоректальної адекарциноми 30 пацієнтів. Установлено, що поліпи дистальної товстої кишки характеризуються цитоплазматичною експресією ALDH1 з медіаною відносною площі 25.63 (18.26; 30.42)% клітин строми, а також, що експресія маркерів епітеліоцитами виявляється виключно в дисплазійно змінених поліпах з медіаною площі 22.13 (17.22; 30.05)%. Колоректальна адекарцинома
ALDH1 is well known as a “metabolic marker” of stem cells, that is based on the main function of the enzyme – protection of cells from oxidative damage and, as a consequence, providing their high survival rate [4]. ALDH1 is expressed by normal stem cells, progenitor cells, and CSCs [11]. A lot of research were devoted to studying the significance of ALDH1 expression in various types of cancer has been accumulated in the current literature [3, 4, 10]. A lot of research were devoted to studying of ALDH1 expression significance in CRA, however, the data obtained are contradictory. In some studies, it was shown that ALDH1 is an independent prognostic marker, high expression of which directly correlates with worsening of prognosis, as well as with clinical and pathomorphological characteristics of the tumor [9]. At the same time, it was shown that the expression of ALDH1 does not correlate with the CRA stage [2]. Furthermore, in the modern literature, there are only single data regarding the features of ALDH1 expression in colorectal polyps, which do not provide a comprehensive picture of the marker significance in the context of colorectal cancerogenesis [9].

The aim of the study was to compare ALDH1 immunohistochemical expression levels in polyps and adenocarcinoma of the distal colon.

**MATERIALS AND METHODS OF RESEARCH**

Histopathological and immunohistochemical (IHC) studies of biopsies from 40 patients (biopsies of polyps and histologically non-changed mucosa of the distal colon), as well as surgical material of colorectal adenocarcinoma from 30 patients, were carried out.

The biopsies and the surgical material were fixed in 10% neutral buffered formalin and were paraffin-embedded. The features of the studied samples histological structure were studied in sections stained by hematoxylin and eosin, and in sections stained by PAS-reaction as well.

IHC study was conducted according to the protocol provided by the manufacturer of used antibodies. Monoclonal antibodies against ALDH1 (ALDH1A1, Clone 5A11, Thermo Scientific, USA), as well as visualization system EnVision FLEX with diaminobenzidine (DAKO, USA), were used. The results of IHC reactions were studied using Axioplan-2 microscope (Carl Zeiss, Germany). In each case, the area of ALDH1-positive cells was estimated in 5 standardized microscope fields of view at ×200 magnification. The area was estimated by the method of photo digital morphometry: calculation of immunopositive pixels number in a digital image with further comparing to total pixels number in the image was carried out. As a result, the number of immunopositive pixels was expressed in % [1].

The obtained data were statistically processed using the STATISTICA® for Windows 13.0 package (StatSoft Inc., license no. JPZ804J382130ARCN10-J). The median (Me), the lower and upper quartiles (Q1; Q3) were calculated. Comparison between two study groups was carried out using the Mann-Whitney test. The results were considered statistically significant at the 95% level (p<0.05) [8].

**RESULTS AND DISCUSSION**

It was found that distal colonic polyps are characterized by cytoplasmic ALDH1 expression in stromal cells, with the median of relative area of ALDH1+ cells equal to 25.63 (18.26; 30.42)% stromal cells (fig. 1). ALDH1+ epitheliocytes are revealed exclusively in dysplastic polyps with the median of the area that is equal to 22.13 (17.22; 30.05)% epitheliocytes.
Colorectal adenocarcinoma is characterized by cytoplasmic ALDH1 expression in both stromal and cancer cells. The median of relative area of ALDH1+ stromal cells is equal to 40.22 (22.54; 47.77)%, while the median of relative area of ALDH1+ cancer cells is equal to 32.12 (23.64; 40.28)% (fig. 2).

Based on the results of histopathological examination, the CRA study group was divided into subgroups according to the pTNM stages. Comparative analysis for the data obtained for the sequent stages was carried out. The median of relative area of ALDH1+ stromal cells in CRA I stage is equal to 20.66 (18.51; 21.47)% vs. the median of relative area of ALDH1+ stromal cells in CRA II stage is equal to 25.75 (20.56; 32.86)%, p<0.05; the median of relative area of ALDH1+ stromal cells in CRA II stage vs. the median of relative area of ALDH1+ stromal cells in CRA III stage is equal to 44.93 (41.17; 50.01)%, p<0.05; the median of relative area of ALDH1+ stromal cells in CRA III stage...
vs. the median of relative area of ALDH1+ stromal cells in CRA IV stage is equal to 48.36 (42.15; 55.17)%, p<0.05.

The median of relative area of ALDH1+ cancer cells in CRA I stage is equal to 26.04 (21.65; 31.94) vs. the median of relative area of ALDH1+ cancer cells in CRA II stage is equal to 30.31 (21.17; 35.68)% , p>0.05; the median of relative area of ALDH1+ cancer cells in CRA II stage vs. the median of relative area of ALDH1+ cancer cells in CRA III stage is equal to 30.28 (21.19; 35.47)% , p>0.05; the median of relative area of ALDH1+ cancer cells in CRA III stage vs. the median of relative area of ALDH1+ cancer cells in CRA IV stage is equal to 48.71 (38.72; 51.16)% , p<0.05.

Thereby, statistically significant increase of the area of ALDH1+ stromal cells in CRA during its progression from I to III stages was revealed. Statistically significant increase of the area of ALDH1+ cancer cells in CRA during its progression from III to IV stages was revealed as well. According to the literature, ALDH1+ cells of CRA stroma are involved in activation of several signaling pathways, including MEK/ERK- and Wnt/β-catenin cascades. It is well known that activation of those cascades forms the basis of invasiveness in different carcinomas, including CRA [3]. ALDH1+ cancer cells are known as cancer cells undergoing epithelial-mesenchymal transition. Based on the literature, the expression of ALDH1 by cancer cells is associated with loss of E-cadherin expression and appearance of vimentin expression [6]. In addition, ALDH1 expression by cancer cells displays their acquisition of stemness. The enzyme performs its main detoxifying function in these cells that leads to their high survival rate [11].

Comparative analysis for the data obtained for both distal colonic polyps and colorectal adenocarcinoma was performed as well. It was revealed that the median of area of ALDH1+ stromal cells in polyps is 2 times smaller than that in CRA: 25.63 (18.26; 30.42)% vs. 40.22 (22.54; 47.77)% , p<0.05. The median of area of ALDH1+ epitheliocytes in polyps is 1.5 times smaller than that for cancer cells in CRA: 22.13 (17.22; 30.05)% vs. 32.12 (23.64; 40.28)% , p<0.05.

It has already been said that in the modern literature there are only single data regarding the features of ALDH1 expression in colorectal polyps [9]. In this study it was shown that the medians of ALDH1+ cells areas are significantly higher in CRA, when compared with those in polyps, that indicates an increasing role of ALDH1 in progression of advanced stages of colorectal carcinogenesis.

**CONCLUSIONS**

1. Distal colonic polyps are characterized by cytoplasmic expression of ALDH1, the median of ALDH1+ stromal cells area in polyps is 2 times smaller than the median of ALDH1+ stromal cells area in carcinoma, and the median of ALDH1+ epitheliocytes area in polyps is 1.5 times smaller than the median of ALDH1+ cancer cells area.

2. Colorectal adenocarcinoma is characterized by cytoplasmic expression of ALDH1, the median of ALDH1+ stromal cells area significantly increases during the tumor progression from stage I to stage III.

3. The median of ALDH1+ cancer cells area significantly increases during the tumor progression from stage III to stage IV that displays increasing in number of cancer cells that acquire stemness on advanced stages of colorectal adenocarcinoma.
