We consider single-particle properties in the one-dimensional repulsive Hubbard model at commensurate fillings in the metallic phase. We determine the real-time evolution of the retarded Green’s function by matrix-product state methods. We find that at sufficiently late times the numerical results are in good agreement with predictions of nonlinear Luttinger liquid theory. We argue that combining the two methods provides a way of determining the single-particle spectral function with very high frequency resolution.

I. INTRODUCTION

The spectral and dynamical properties of one-dimensional fermionic systems have attracted a significant amount of interest in recent years due to advances in both low-dimensional materials and cold atom experiments. The repulsive Hubbard model constitutes a key paradigm for studying strong correlation effects in these systems. Its Hamiltonian is

\[ H = -t \sum_{j,\sigma} \left( c_{j,\sigma}^\dagger c_{j+1,\sigma} + c_{j+1,\sigma}^\dagger c_{j,\sigma} \right) + U \sum_{j} n_{j,\uparrow} n_{j,\downarrow} - \mu \sum_{j} n_{j,\uparrow} - n_{j,\downarrow} \]

where \( n_{j,\sigma} = c_{j,\sigma}^\dagger c_{j,\sigma} \) and \( n_{j} = n_{j,\uparrow} + n_{j,\downarrow} \). In one dimension, it is exactly solvable via the Bethe Ansatz, with many results about the model available in the literature. However, the computation of dynamical correlation functions analytically and directly from the Bethe Ansatz remains a difficult task. An example of particular interest is the single-particle spectral function

\[
A(\omega, k) = -\frac{1}{\pi} \text{Im} \, G_{\text{ret}}(\omega, k), \\
G_{\text{ret}}(\omega, k) = -i \int_{0}^{\infty} dt \, e^{i\omega t} \sum_{l} e^{-ilna_{0}} \\
\times \langle \psi_{0}|c_{j+1,\sigma}(t), c_{j,\sigma}^\dagger|\psi_{0}\rangle,
\]

where \( |\psi_{0}\rangle \) is the ground state. The spectral function is accessible through angle-resolved photoemission experiments. Such measurements on the quasi-1D organic conductor TTF-TCNQ have been interpreted in terms of \( A(\omega, k) \) of the 1D Hubbard model.

One approach to calculating properties of the spectral function is via Luttinger liquid theory. Certain low-energy aspects of the Hubbard model in zero magnetic field are described by the bosonized Hamiltonian \( H = H_c + H_s \)

\[
H = \sum_{\alpha=c,s} \frac{v_{\alpha}}{2\pi} \int dx \left[ \frac{1}{K_{\alpha}} \left( \frac{\partial \Phi_{\alpha}}{\partial x} \right)^2 + K_{\alpha} \left( \frac{\partial \Theta_{\alpha}}{\partial x} \right)^2 \right] + \ldots
\]

where the dots indicate the presence of irrelevant operators, which means that their respective coupling constants approach zero under the renormalization group flow. Neglecting the effects of the irrelevant operators in (3) makes it possible to calculate \( A(\omega, k) \) at low energies. The spectral function is found to exhibit singularities following the dispersions of the collective spin (“spinon”) and charge (“holon”) excitations. A problem with this Luttinger liquid approach to dynamical correlation functions is that the latter inherently involve a finite energy scale (e.g. the frequency \( \omega \) in (2)), and the coupling constants of irrelevant perturbations (3) will, at best, be small but finite at the scale \( \omega \).

In a number of works, it was demonstrated, for the case of spinless fermions, that taking the irrelevant operators perturbing the Luttinger liquid Hamiltonian into account generally leads to significant changes in the singularities characterizing the dominant features seen in response functions. Exact expressions for these singular features in response functions were obtained using a mapping to a Luttinger liquid coupled to a mobile impurity. Crucially, unlike in unperturbed Luttinger liquid theory, the exponents characterizing these singularities are generally momentum dependent. The generalization to spinful fermions, and the Hubbard model in particular, was considered in several recent works.

The case of the Mott-insulating phase beyond the field theory regime, was treated in Ref. , and a rather complete understanding of the dynamical structure factor was obtained.

In the metallic case of the Hubbard model (less than one electron per site), a mobile impurity model for the singular features in the single-particle spectral function was formulated. Combined with the Bethe Ansatz solution this allowed the calculation of exact expressions for the power-law singularities occurring at the “absolute
threshold\textsuperscript{33}. These results were found to be in accord with previous analytic work based on completely different methods and assumptions\textsuperscript{33}. On the other hand, a comparison of the analytic predictions\textsuperscript{30} to available dynamical density matrix renormalization group (dDMRG)\textsuperscript{34,35} results on the quarter-filled Hubbard model\textsuperscript{5} was found to be rather unconvincing. A serious complication is that the dDMRG method used in Ref. \textsuperscript{5} requires a finite imaginary part of the frequency, while the window in frequency space over which the calculated power law applies in general will be narrow. This makes extracting power-law singularities from dDMRG results in the momentum/frequency domain inherently difficult.

In this work, we employ a numerical approach to check the validity of the results for threshold singularities in response functions obtained by mobile impurity models. Using the time-evolving block decimation method (TEBD), formally equivalent to time-dependent density matrix renormalization group (tDMRG), cf.Refs. \textsuperscript{28,36-38}, we compute the retarded Green’s function in the momentum/time domain for a variety of fillings and interaction strength. As we will see, these results are well described by a fit to a power-law decay expression whose frequencies and exponents are fixed by combining Bethe Ansatz results with an appropriate mobile impurity model.

The paper is organized as follows. In section II we present the single-particle spectrum through the spectral function $A(\omega, k)$ calculated using TEBD. In section III we identify its main features in terms of the exact excitation spectrum known from Bethe Ansatz\textsuperscript{3} and present results for edge exponents obtained from appropriate mobile impurity models. Implications of these findings for real-time dynamics are summarized in section IV. Section V is devoted to a comparison of these results to the numerically calculated Green’s function in the momentum/time domain. We summarize our results in section VI.

II. NUMERICAL STUDY OF THE SPECTRAL FUNCTION

We first use the DMRG algorithm to find the ground state $|\psi_0\rangle$ of the Hamiltonian (1) in an MPS representation, and then the TEBD algorithm to obtain its dynamical properties (details of the numerical method used can be found in Refs \textsuperscript{55,56,72-74}). In particular, we
calculate the retarded single-particle Green’s function
\[ G^h(t, j) = -i \langle \psi_0 | c^d_j(t) c_j(0) | \psi_0 \rangle, \] (4)
\[ G^p(t, j) = -i \langle \psi_0 | c_j(t) c^d_j(0) | \psi_0 \rangle. \] (5)

For this, a fermionic operator \( c_{\alpha j} \) or \( c^d_{\alpha j} \) (the spin index is suppressed for clarity) is applied to the ground state MPS, at the central site of a finite chain \( j_0 = L/2 \), and then the resulting state is evolved in time. We use open chains of length \( L = 300 \), and let the bond dimensions grow with time such that the truncation error is at most \( 10^{-5} \) per step. A fourth-order Suzuki-Trotter decomposition with time steps of \( \sim 0.05 \) is employed. The maximum time is chosen such that the wave-front of the “light-cone” of correlations does not reach the edges of the system, which introduces a cutoff at small frequencies. Before performing a Fourier transform of the data, the sampled time is extended using linear prediction, improving the energy resolution. In order to set the Fermi level at \( \epsilon_F = 0 \), the chemical potential \( \mu \) is adjusted so that \( E_0(N-1) = E_0(N) \) where \( E_0(N) \) is the ground state energy with \( N \) electrons.

Throughout this paper we concentrate on the hole part of the Green’s function \( G^h \), and consequently the presented spectral function only has support for negative frequencies \( \omega < 0 \). This spectral function is the quantity experimentally relevant to photoemission spectra. The spectral function for filling factors \( \rho = 1/4 \) and \( \rho = 1/6 \) with interaction strengths \( U = 5 \) and \( U = 10 \) is shown in Fig. 1. The main characteristics of the spectral function for \( |k| < k_F \) can be clearly observed, as previously reported in e.g. Ref. [5]. The sharp line at the top corresponds to the spinon branch and the lines below correspond to the holon branch. These excitations of the Hubbard model are thoroughly described in the next section from the point of view of Bethe Ansatz (dashed lines in Fig. 1). The main focus of the remainder of the paper will consist in analysing the threshold singularities at the edge of these transition lines for \( |k| < k_F \). For \( |k| > k_F \) there is a strong decay in the spectral weight and further features in the spectral function are difficult to observe for these parameters.

III. EXCITATIONS IN THE HUBBARD MODEL AND DOMINANT FEATURES IN THE SPECTRAL FUNCTION

A detailed discussion of the excitation spectrum of the Hubbard model is given in Ref. [3] (see also Refs. [29]). The particular excitations relevant to the description of the single-particle Green’s function have been constructed in detail in Ref. [30], and we now summarize the relevant results given there. We consider the case of zero magnetic field and \( N \) electrons on an \( L \)-site periodic chain. The Fermi momentum is then
\[ k_F = \frac{\pi N}{2L}. \] (6)

The dominant features in the (hole) spectral function at momentum \( |q| < k_F \) arise from the holon-spinon excitation carrying charge +e and spin 1/2. Its energy and momentum are
\[ E_{hs}(k^h, \Lambda^h) = -\varepsilon_c(k^h) - \varepsilon_s(\Lambda^h), \]
\[ P_{hs}(k^h, \Lambda^h) = -p_c(k^h) - p_s(\Lambda^h) \pm 2k_F, \] (7)
where \( |k^h| < Q \) and \( -\infty < \Lambda^h < \infty \) parametrize the excitation. The functions \( \varepsilon_{c,s} \) and \( p_{c,s} \) are obtained from the solutions of coupled linear integral equations and are given in (19) and (28) of Ref. [30] respectively. Because of parity invariance the Green’s function is symmetric in momentum and we therefore restrict ourselves to the momentum range
\[ 0 \leq P_{hs} \leq k_F. \] (8)

A. Absolute Threshold: spinon edge

The absolute threshold for \( 0 < P_{hs} < k_F \) was analyzed in detail in Ref. [30]. It is obtained by choosing the plus sign in (7), fixing \( k_h = Q \), and then varying \( \Lambda^h \) in the range
\[ -\infty < \Lambda^h \leq 0. \] (9)

At energies just above this threshold, the spectral function exhibits a power-law singularity (as a function of frequency for fixed momentum)
\[ A(\omega, P_{hs}(Q, \Lambda^h)) \propto (\omega - E_{hs}(Q, \Lambda^h))^{-\mu_{0,-}}, \] (10)
where the exponent \( \mu_{0,-} \) is given in (130) of Ref. [30].

B. Holon edge

The other dominant features in the spectral function arise in the vicinity of the holon edge, obtained by choosing the minus sign in (7), setting \( \Lambda^h = -\infty \) and varying \( k^h \) in the range
\[ -Q \leq k^h < 0. \] (11)

The range of the corresponding momentum is \( -k_F \leq P_{hs} < k_F \). We note that by virtue of parity invariance this particular branch is sufficient for describing both high-energy features in the spectral function \( A(\omega, 0 < q < k_F) \). We now assume that, as a consequence of the integrability of the Hubbard model, a threshold singularity occurs just above the holon edge (as a function of frequency for fixed momentum)
\[ A(\omega, P_{hs}(k^h, -\infty)) \propto (\omega - E_{hs}(k^h, -\infty))^{-\mu_{0,-}}. \] (12)
The assumption that in integrable models threshold singularities occur even at thresholds of excitations that sit on top of continua, into which they are kinematically allowed to decay, appears reasonable: for massive integrable quantum field theories this has been seen to be the case [30]. In non-integrable models one does not expect singular behaviour [25]. The exponent $\mu_{0,-}^c$ can then be calculated in the framework of a mobile impurity model using input from the Bethe Ansatz solution. Some details of this calculation are given in Appendix [A]. The result for the threshold exponent is

$$\mu_{0,-}^c = \frac{1}{2} - K_e \left( \frac{1}{2} - 2D_e^{\text{imp}} \right)^2 - \left( \frac{N_c^{\text{imp}}}{4K_e} \right)^2,$$

(13)

where $K_e$ is the Luttinger liquid parameter (cf (119) and (103) of [30]),

$$N_e^{\text{imp}} = \int_{-Q}^{Q} dk \rho_{c,1}(k),$$

$$2D_e^{\text{imp}} = \Phi(k^h) + \int_{-Q}^{Q} dk \left( \rho_{c,1}(-k) - \rho_{c,1}(k) \right) - \int_{-Q}^{Q} dk \rho_{c,1}(k) \Phi(k),$$

$$\Phi(k) = \frac{i}{\pi} \ln \left[ \frac{\Gamma \left( \frac{1}{2} + \frac{i \sin k}{4\omega} \right) \Gamma \left( 1 - \frac{i \sin k}{4\omega} \right)}{\Gamma \left( \frac{1}{2} - \frac{i \sin k}{4\omega} \right) \Gamma \left( 1 + \frac{i \sin k}{4\omega} \right)} \right],$$

(14)

and the function $\rho_{c,1}$ is the solution of the integral equation

$$\rho_{c,1}(k) = - \cos k \left( \frac{\sin k - \sin k^h}{4\omega} \right) + \cos k \int_{-Q}^{Q} dk' \rho_{c,1}(k') \rho_{c,1}(k'),$$

(15)

Here $u = U/4$ and

$$R(x) = \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \frac{e^{i\omega x}}{1 + \exp(2u|\omega|)}.$$

(16)

In Figs. 2 and 3 we plot the value of the exponent $\mu_{0,-}^c$ as a function of momentum for several values of interaction strength $U$ and band fillings $1/4$ and $1/6$ respectively. We note that our results are again in accord with those of Refs. [33].

![Figure 3](image_url)

**FIG. 3.** (Color online) Exponent $\mu_{0,-}^c$ for $\rho = 1/6$ as a function of momentum as derived from the mobile impurity model approach for various fillings and values of $U$.

### IV. MOBILE IMPURITY MODEL AND REAL-TIME DYNAMICS

We have seen above that for a given momentum $0 < k < k_F$ the single-particle spectral function exhibits threshold singularities at frequencies

$$\omega_1 = E_{hs}(Q, \Lambda^h), \quad P_{hs}(Q, \Lambda^h) = k,$$

$$\omega_2 = E_{hs}(k^h, -\infty), \quad P_{hs}(k^h, -\infty) = k,$$

$$\omega_3 = E_{hs}(k^h, -\infty), \quad P_{hs}(k^h, -\infty) = -k.$$

(17)

Assuming that the singular features in the spectral function give the dominant behaviour of the retarded Green’s function at late times, we conclude that the latter should be (approximately) of the form

$$G(t, k) \sim \sum_{\alpha} A_{\alpha} e^{i\omega_{\alpha} t + \phi_{\alpha} t - \gamma_{\alpha}},$$

(18)

where the threshold exponents $\gamma_{\alpha}$ are related $\gamma_{\alpha} = \mu_{0,-}^c + 1$ to the exponents calculated with the mobile impurity method. All parameters are a function of momentum $k$. Here $A_{\alpha}$ are complex amplitudes and $\phi_{\alpha}$ are real phases and it is currently not known how to determine them a priori, see however Refs. [11]. Table I gives explicit values for the frequencies $\omega_{\alpha}$ and exponents $\mu_{\alpha}$, to be compared with TEBD results.
TABLE I. Values for the parameters of the power-law decay function (18), calculated from the Bethe Ansatz and mobility impurity model.

| $\rho$ | $U$ | $k$ | $\omega_1$ | $\omega_2$ | $\omega_3$ | $\mu_{0,-}$ | $\mu_{3,-}$ |
|-------|-----|-----|------------|------------|------------|-------------|-------------|
| $1/4$ | 5   | 0   | 1.15       | 0.387      | 0.387      | 0.373       | 0.855       |
| $1/4$ | 5   | $\pi/8$ | 0.661      | 0.277      | 1.46       | 0.392       | 0.782       |

| $1/6$ | 10  | $\pi/8$ | 0.195      | 0.0384     | 0.856      | 0.354       | 0.545       |

V. COMPARISON WITH NUMERICAL RESULTS

The formula (18) for $G(t,k)$ has too many free parameters to reliably fit the numerical data from TEBD simulations, obtained through a Fourier transform of the (hole) Green’s function (4). Therefore, we fix the threshold frequencies $\omega_\alpha(k)$ and the exponents $\gamma_\alpha(k)$ to the values $G(t,k)$ calculated with the mobile impurity approach, leaving the momentum-dependent amplitudes and phases as the only free parameters. We fit the imaginary part of $G(t,k)$ to the ansatz but the procedure holds equally well with the real part. The data used for the fitting procedure are not extended in time with linear prediction. The time evolution of the Green’s function is illustrated for $\rho = 1/4$ in Fig. 4 for $U = 5$ and $U = 10$, both at $k = 0$ and $k = \pi/8$. The initial time of the fit is adjusted in each case in order to avoid non-universal behaviour at short times. For later times, the decay of $G(t,k)$ is very well reproduced by the fitting ansatz (18). The good quality of the fits to the numerical data is the main result of our paper, which validates the mobile impurity approach. As the momenta approaches $k_F$, the quality of the fit worsens slightly. One can understand this, since the frequency at which the first singularity develops approaches $\omega \to 0$, which is more difficult to capture with a TEBD approach, inherently limited to a given finite time.

The same behaviour is essentially observed for $\rho = 1/6$ in Fig. 5. The relaxation to a universal behavior is slower for $\rho = 1/6$, which agrees with the poorer resolution in frequency space observed in Fig. 1.

As the fitting approach nicely reproduces the long-
time behavior, we can use it instead of linear prediction to extend the raw TEBD data to longer times. In the combined TEBD+BA approach we extrapolate the real-time data by orders of magnitude using the ansatz (18) with parameters taken from the analytical approach and the fitting procedure outlined above. Such a combined method dramatically increases the frequency resolution of the resulting spectral function with clearly defined singularity peaks, as shown in Fig. 6 for the case of \( \rho = 1/4 \) and \( U = 10 \). The spectral functions from both approaches have been normalized to obey the momentum-distribution function sum rule \( \int_{-\infty}^{0} A(\omega, k) = n(k) \).

**VI. CONCLUSIONS**

In this work we have studied the single particle Green’s function \( G(t, k) \) of the one-dimensional repulsive Hubbard model in the metallic regime. Using matrix product state techniques we computed \( G(t, k) \) for a variety of band fillings and interaction strengths for large systems (\( L = 300 \)) and times \( 0 < t \lesssim 60 \) (in units of the hopping). We then employed mobile impurity models in tandem with the Bethe Ansatz solution to obtain an expression for the late time asymptotic behaviour of the Green’s function. Using the unknown coefficients in the resulting expression as fit parameters, we obtained an excellent agreement with the numerical results at late times. This strongly suggests that the mobile impurity results are not only correct, but are of practical value. Moreover it removes concerns based on the poor agreement between threshold singularity exponents (in the frequency domain) obtained by mobile impurity models\cite{30} and earlier dynamical DMRG computations\cite{5}. Finally, we have shown that combining the numerical results at short and intermediate times with the asymptotic form dictated by the mobile impurity model, it is possible to obtain results for the single particle spectral function with unprecedented frequency resolution. We expect this observation to be of practical use also in further cases.

**ACKNOWLEDGMENTS**

**Appendix A: Calculation of the Holon Edge Exponent**

In this appendix we summarize the technical details underlying our calculation of edge exponents in the framework of mobile impurity models.

1. **Finite-size energy levels**

A key input in determining edge exponents is the finite-size excitation spectrum in presence of a high-energy holon. The latter can be obtained in a complete analogy to the calculation of the excitation spectrum in the vicinity of the spinon edge in Ref. \cite{30}. The result of this calculation is
\[
E(\Delta N_c, \Delta N_s, D_c, D_s) = L \varepsilon_{GS} - \varepsilon_c(k) - \frac{\pi}{6L} (v_s + v_c) - \frac{1}{L} \varepsilon_c'(k)\delta k^h \\
+ \frac{2\pi v_c}{L} \left\{ \frac{(\Delta N_c - N_c^{imp})^2}{4\xi^2} + \xi^2 \left( D_c - D_c^{imp} + \frac{D_s - D_s^{imp}}{2} \right)^2 \right\} \\
+ \frac{2\pi v_s}{L} \left\{ \frac{1}{2} \left( \Delta N_s - \Delta N_s^{imp} + \frac{N_c^{imp}}{2} \right)^2 + \frac{(D_s - D_s^{imp})^2}{2} \right\}.
\]  

The various quantities entering (A1) are as follows

1. The dressed energy for holons \( \varepsilon_c(k) \) is a solution to the integral equation

\[
\varepsilon_c(k) = -2 \cos(k) - \mu - 2u \\
+ \int_{-Q}^{Q} dk' \cos(k') R(\sin(k) - \sin(k')) \varepsilon_c(k'), \\
\varepsilon_c(\pm Q) = 0,
\]

where the function \( R(x) \) is given in (10);

2. \( \varepsilon_c'(k) \) is the derivative of \( \varepsilon_c(k) \) with respect to \( k \);

3. \( \varepsilon_{GS} \) is the ground state energy per site

\[
\varepsilon_{GS} = \int_{-Q}^{Q} \frac{dk}{2\pi} \varepsilon_c(k) + u;
\]

4. The spin and charge velocities \( v_{s,c} \) are obtained as

\[
v_s = \frac{\varepsilon_s'(\infty)}{2\pi \rho_s(\infty)}, \quad v_c = \frac{\varepsilon_c'(Q)}{2\pi \rho_c(Q)},
\]

\[
\varepsilon_s(\Lambda) = \int_{-Q}^{Q} dk \cos(k) s(\Lambda - \sin(k)) \varepsilon_c(k),
\]

\[
\rho_c(k) = \frac{1}{2\pi} + \cos(k) \int_{-Q}^{Q} dq R(\sin(k) - \sin(q)) \rho_c(q),
\]

\[
\rho_s(\Lambda) = \int_{-Q}^{Q} dk s(\Lambda - \sin(k)) \rho_c(k);
\]

where

\[
s(x) = \frac{1}{4u \cosh \left( \frac{\pi x}{4u} \right)};
\]

5. The dressed charge \( \xi = \xi(Q) \) is obtained from the solution of the integral equation

\[
\xi(k) = 1 + \int_{-Q}^{Q} dk' \cos(k') R(\sin(k) - \sin(k')) \xi(k');
\]

6. The quantities \( N_{c,s}^{imp} \) and \( D_{c,s}^{imp} \) are given by

\[
N_c^{imp} = \int_{-Q}^{Q} dk \rho_{c,1}(k),
\]

\[
N_s^{imp} = \int_{-\infty}^{\infty} d\Lambda \rho_{s,1}(\Lambda) = \frac{1}{2} (N_c^{imp} - 1),
\]

\[
2D_c^{imp} = \int_{-Q}^{Q} dk [\rho_{c,1}(-k) - \rho_{c,1}(k)] + \frac{i}{\pi} \ln \left[ \frac{\Gamma \left( \frac{1}{2} + i \frac{\sin k^h}{4u} \right) \Gamma \left( 1 - i \frac{\sin k^h}{4u} \right)}{\Gamma \left( \frac{1}{2} - i \frac{\sin k^h}{4u} \right) \Gamma \left( 1 + i \frac{\sin k^h}{4u} \right)} \right],
\]

\[
D_s^{imp} = 0;
\]

7. \( \Delta N_{c,s} \) and \( D_{c,s} \) are quantum numbers describing the excitation under consideration. If we only have a high-energy holon with rapidity \( k^h \) and a low-energy spinon sitting at its Fermi point \( \Lambda^h = -\infty \),
\[ \Delta N_c = 0 \, , \, \Delta N_s = -1 \, , \, D_c = D_s = \frac{1}{2}. \quad (A8) \]

The identification \[ (A8) \] follows from the definition of \( \Delta N_{c,s} \) and \( D_{c,s} \) in terms of the (half-odd) integers characterizing a given solution of the Bethe Ansatz equation, cf Ref. \[ [30] \].

8. The “order 1” part \( k_h \) of the holon rapidity is determined by the requirement

\[ z_c(k_h) = k_h + \int_{-\infty}^{\infty} d\Lambda \rho_s(\Lambda) \theta\left(\frac{\sin k_h - \Lambda}{u}\right) = 2\pi T_h \frac{\Lambda}{L}, \quad (A9) \]

where \( T_h \) is a (half-odd) integer number characterizing the momentum of the holon;

9. The parameter \( \delta k_h \) describes the “order 1/L” part of holon rapidity in the finite volume, and for zero magnetic field is given by

\[ \rho_{c,0}(k_h) \delta k_h = -\int_{-\infty}^{\infty} \frac{d\Lambda}{2\pi} \rho_{s,1}(\Lambda) \theta\left(\frac{\sin k_h - \Lambda}{u}\right) - \int_{-\infty}^{\infty} \frac{d\Lambda}{2\pi} \sum_{\sigma = \pm} r^{(\sigma)}(\Lambda) \theta\left(\frac{\sin k_h - \Lambda}{u}\right)(Q_{\sigma} - \sigma Q) + \frac{1}{2\sqrt{2}} \quad (A10) \]

where the quantities \( r^{(\sigma)}(z) \) satisfy

\[ r^{(\sigma)}(k) = \cos k \int_{-Q}^{Q} dk' R(\sin k - \sin k') r^{(\sigma)}(k'), \]

\[ + \sigma \cos k R(\sin k - \sigma \sin Q), \quad (A11) \]

\[ r^{(\sigma)}(\Lambda) = \int_{-Q}^{Q} dk s(\Lambda - \sin k) r^{(\sigma)}(k) + \sigma s(\Lambda - \sigma \sin Q). \quad (A12) \]

2. Impurity model and field theory

The appropriate mobile impurity model for describing the holon edge is \[ H_{c} + H_{s} + H_{\text{int}} + H_{d} \], where

\[ H_{c} = \frac{v_{c}}{2\pi} \int dx \left[ \frac{1}{K_{c}} \left( \frac{\partial \Phi_{c}}{\partial x} \right)^{2} + K_{c} \left( \frac{\partial \Theta_{c}}{\partial x} \right)^{2} \right], \quad (A13) \]

\[ H_{\text{int}} = \int dx \left[ \frac{V_{R} - V_{L}}{2\pi} \partial_{x} \Theta_{c} - \frac{V_{R} + V_{L}}{2\pi} \partial_{x} \Phi_{c} \right] d^{1}, \]

\[ H_{d} = \int dx d^{1}(x) \left[ \varepsilon_{c}(P) - iu \partial_{x} \right] d(x), \quad (A14) \]

Here the Bose fields \( \Phi_{c} \) and the dual fields \( \Theta_{c} \) fulfil the commutation relations \( \left[ \Phi_{c}(x), \frac{\partial \Phi_{c}}{\partial y} \right] = i\pi \delta_{\alpha \beta} \delta(x - y) \), \( d(x) \) and \( d^{1}(x) \) are annihilation and creation operators of the mobile impurity, which carries momentum \( P \) and travels at velocity \( u \). The parameters \( V_{R,L} \) characterize the interaction of the impurity with the low energy charge degrees of freedom. The parameters of \( H_{c,s} \) and \( H_{d} \) in \[ (A14) \] are readily identified with quantities obtained from the Bethe Ansatz. The spin and charge velocities \( v_{s,c} \) are given by \[ (A4) \] and the Luttinger parameters are

\[ K_{s} = 1, \quad K_{c} = \frac{\xi^{2}}{2}, \quad (A15) \]

where \( \xi \) is given by \[ (A6) \]. The velocity of the impurity is expressed in terms of the solutions to the integral equations \[ (A2) \], \[ (A4) \] as

\[ u = \frac{\varepsilon_{c}'(k_{h})}{2\pi \rho_{c}(k_{h})}, \quad (A16) \]

The position \( k_{h} \) of the hole is fixed by the requirement

\[ P_{hs}(k_{h}) = P. \quad (A17) \]

The parameters \( V_{R,L} \) entering the expression for \( H_{\text{int}} \) are determined as follows. Following Ref. \[ [29] \] we remove the interaction term \( H_{\text{int}} \) through the unitary transformation \( U^{\dagger} H U \)

\[ U^{\dagger} = \exp \left( -i \int dx \left[ \sqrt{K_{c}} \frac{\Delta \delta_{+,-}}{2\pi} \Theta_{c}(x) \right. \right. \]

\[ - \left. \frac{\Delta \delta_{+,-}}{2\pi \sqrt{K_{c}}} \Phi_{c}(x) \right] d(x) d^{1}(x) \), \quad (A18) \]

where

\[ (V_{L} + V_{R}) K_{c}^{\dagger} = (v_{c} + u) \Delta \delta_{-,-} \pm (v_{c} - u) \Delta \delta_{+,-}. \quad (A19) \]

In the resulting Hamiltonian the impurity no longer interacts explicitly with the charge part of Luttinger liquid, which in the transformed basis takes the form

\[ U^{\dagger} H_{c} U = \frac{v_{c}}{2\pi} \int dx \left[ \frac{1}{K_{c}} \left( \frac{\partial \Phi_{c}}{\partial x} \right)^{2} + K_{c} \left( \frac{\partial \Theta_{c}}{\partial x} \right)^{2} \right]. \quad (A20) \]
The main effect of the unitary transformation is to change the boundary conditions of the charge boson. In particular one has
\[ \partial_x \tilde{\Phi}_c = U^1 \partial_x \Phi_c U = \partial_x \Phi_c + \frac{\sqrt{K_c}}{2} \left( \Delta \delta_{+,c} - \Delta \delta_{-,c} \right) dd^1, \]
\[ \partial_x \tilde{\Theta}_c = U^1 \partial_x \Theta_c U = \partial_x \Theta_c - \frac{1}{2\sqrt{K_c}} \left( \Delta \delta_{+,c} + \Delta \delta_{-,c} \right) dd^t. \]
(A21)

Equations (A21) imply that the finite-size spectrum of \( (A20) \) in presence of a high-energy holon impurity can be cast in the form
\[
\Delta E = \frac{2\pi v_c}{L} \left[ \frac{1}{8K_c} (\Delta n_c + \sqrt{2K_c} \frac{\Delta \delta_{+,c} - \Delta \delta_{-,c}}{2\pi})^2 + \frac{K_c}{4} (4d_c + 2d_s - \frac{\Delta \delta_{+,c} + \Delta \delta_{-,c}}{2\pi \sqrt{2K_c}})^2 + \sum_{n>0} n [M_{n,c}^+ + M_{n,c}^-] \right] + \frac{2\pi v_s}{L} \left[ \frac{1}{2} \left( \Delta n_s - \frac{\Delta n_c}{2} \right)^2 + \frac{d_s^2}{2} + \sum_{n>0} n [M_{n,s}^+ + M_{n,s}^-] \right],
\]

(A22)

\[ \Delta n_\alpha = -\frac{\sqrt{2}}{\pi} \int dx \langle \partial_x \Phi_\alpha \rangle, \]
\[ 4d_\alpha = \frac{\sqrt{2}}{\pi} \int dx \langle \partial_x \Theta_\alpha \rangle, \]
\[ \alpha = c, s. \]  
(A23)

For the holon edge threshold we have
\[ \Delta n_c = 0, \quad d_c = \frac{1}{2}, \quad \Delta n_s = -1, \quad d_s = \frac{1}{2}. \]  
(A24)

Comparing the resulting energies to the Bethe Ansatz form (A1) we conclude that
\[ N_c^{imp} = -\sqrt{2K_c} \frac{\Delta \delta_{+,c} - \Delta \delta_{-,c}}{2\pi}, \]
\[ 2D_c^{imp} = -\frac{1}{2} + \frac{1}{2\sqrt{2K_c}} \frac{\Delta \delta_{+,c} + \Delta \delta_{-,c}}{2\pi}. \]  
(A25)

### 3. Holon Edge Exponent

Given the phase shifts \( \Delta \delta_{c,\pm} \), the holon edge exponent can be obtained following Ref. \[29\]. The result is
\[ \mu_{0,-}^c = \frac{1}{2} - K_c \left( \frac{1}{2} - 2D_c^{imp} \right)^2 - \frac{(N_c^{imp})^2}{4K_c}. \]  
(A26)

It is useful to consider particular limiting cases:

1. **Infinite interaction limit** \( u \to \infty \)
   \[ \lim_{u \to \infty} \mu_{0,-}^c = \frac{1}{2} - \frac{K_c}{4} = \frac{3}{8}. \]  
   (A27)

As expected, this agrees with Ref. \[29\].

2. **\( k \to k_F \) limit**: here the result is
   \[ \lim_{k \to k_F} \mu_{0,-}^c = \frac{1}{2} - K_c \left( \frac{1}{2} - \frac{1}{\sqrt{2K_c}} \right)^2 - \frac{(1 - \sqrt{2K_c})^2}{4K_c}. \]  
   (A28)

This is different from the Luttinger liquid result
\[ \mu_c^\perp = \frac{1}{2} - \frac{1}{8} \left( K_c + \frac{1}{K_c} - 2 \right). \]  
(A29)
