ABSTRACT

Context. We report the detection by the AGILE (Astro-rivelatore Gamma a Immagini LEggero) satellite of an intense gamma-ray flare from the source AGL J1511-0909, associated with the powerful quasar PKS 1510-089, during ten days of observations from 23 August to 1 September 2007.

Aims. During the observation period, the source was in optical decrease following a flaring event monitored by the GLAST-AGILE Support Program (GASP) of the Whole Earth Blazar Telescope (WEBT). The simultaneous gamma-ray, optical, and radio coverage allows us to study the spectral energy distribution and the theoretical models based on the synchrotron and inverse Compton (IC) emission mechanisms.

Methods. AGILE observed the source with its two co-aligned imagers, the Gamma-Ray Imaging Detector and the hard X-ray imager Super-AGILE sensitive in the 30 MeV – 50 GeV and 18 – 60 keV bands, respectively.

Results. Between 23 and 27 August 2007, AGILE detected gamma-ray emission from PKS 1510-089 when this source was located ∼ 50” off-axis, with an average flux of (270 ± 65) × 10^{-8} photons cm^{-2} s^{-1} for photon energy above 100 MeV. In the following period, 28 August - 1 September, after a satellite re-pointing, AGILE detected the source at ∼ 35” off-axis, with an average flux (E > 100 MeV) of (195 ± 30) × 10^{-8} photons cm^{-2} s^{-1}. No emission was detected by Super-AGILE, with a 3σ upper limit of 45 mCrab in 200 ksec.

Conclusions. The spectral energy distribution is modelled with a homogeneous one-zone synchrotron self Compton (SSC) emission plus contributions by external photons: the SSC emission contributes primarily to the X-ray band, whereas the contribution of the IC from the external disc and the broad line region match the hard gamma-ray spectrum observed.

Key words. gamma-rays: observations – mechanism: non-thermal – quasars: individual (PKS 1510-089)
1. Introduction

The radio source PKS 1510-089 was first identified optically as a quasar with an ultraviolet excess, a visual magnitude of 16.5 (Bolton & Ekers 1966), and a redshift of $z = 0.361$ measured from its emission-line spectrum (Burbidge & Kinnan 1966). PKS 1510-089 is a radio-loud highly polarized quasar (HPQ) belonging to the class of the flat spectrum radio quasar (FSRQ) in terms of its spectral energy distribution. Its radiative output is dominated by the gamma-ray component, while its synchrotron emission peaks around IR frequencies below a pronounced UV bump, presumably due to the thermal emission from the accretion disc (Malkan & Moore 1986, Pian & Treves 1993).

PKS 1510-089 has been extensively observed in X-rays by EXOSAT (Singh, Rao & Vahia 1990, Sambruna et al. 1994), GINGA (Lawson & Turner 1997), ROSAT (Siebert et al. 1998), ASCA (Singh, Shrader & George 1997) and Chandra (Gambill et al. 2003). The observed X-ray spectrum was very flat in the $2 \div 10$ keV band (photon index $\Gamma \approx 1.3$), but steepened in the ROSAT bandpass below 2 keV ($\Gamma \approx 1.9$). Observations by BeppoSAX (Tavecchio et al. 2000) confirm the presence of a soft X-ray excess below 1 keV. A similar soft excess has been detected in other blazars such as 3C273, 3C279, and 3C454.3, and the origin of the soft X-ray excess is still an open issue.

PKS 1510 was recently observed by Suzaku in August 2006 over approximately three days, and the campaign continued with Swift monitoring over 18 days (Kataoka et al. 2007). Swift-XRT observations reveal significant spectral evolution of the X-ray emission on timescales of one week: the X-ray spectrum becomes harder as the source gets brighter.

Gamma-ray emission from PKS 1510-089 was detected by the EGRET instrument on board CGRO with a integrated flux above 100 MeV between (13 ± 5) and $(49 \pm 18) \times 10^{-8}$ photons cm$^{-2}$ s$^{-1}$ and an energy spectrum modelled with a power law with a photon index $\Gamma = 2.47 \pm 0.21$. In this Letter we present the analysis of the AGILE data obtained during the PKS 1510-089 observations from 23 August 2007 to 1 September 2007.

2. AGILE observation of PKS 1510-089

The AGILE scientific Instrument (Tavani et al. 2008) is very compact and combines four active detectors yielding broad-band coverage from hard X-rays to gamma rays.

The Gamma-Ray Imaging Detector (GRID) consists of a combination of a silicon tracker (Prest et al. 2003, Barbiellini et al. 2001), a non-imaging Cesium Iodide Mini-Calorimeter (MCAL; Labanti et al. 2006) positioned under the silicon tracker and sensitive in the 0.3 − 100 MeV energy band, and a segmented anticoincidence system (ACS) made of a plastic shield which surrounds all active detectors (Perotti et al. 2006). A co-aligned coded-mask hard X-ray imager (SuperAGILE; Costa et al. 2001, Feroci et al. 2007) ensures coverage in the 18 $\div$ 60 keV energy band.

The GRID has a field of view of $\sim 2.5$ sr, an angular resolution of 1.2$^\circ$ at 400 MeV (68% cont. radius), an effective area of $\sim 500$ cm$^2$ above 100 MeV, and an energy resolution $\Delta E/E \sim 1$ at 400 MeV. The silicon tracker and the on-board trigger logic are optimized for gamma-ray imaging in the 30 MeV $\div$ 50 GeV energy band (Argan et al. 2004).

The AGILE observations of the PKS 1510-089 were performed from 23 August 2007 12:00 UT to 1 September 2007.
Fig. 3. a) AGILE-GRID gamma-ray light curve, with a 1-day resolution, for the observation period 2007 August 28 - September 1, for photons with $E > 100$ MeV in units of $10^{-5}$ photons cm$^{-2}$ s$^{-1}$. b) R-band optical light curve as observed by the GASP of the WEBT for the observation period 2007 July 26 - September 11. c) GASP radio light curve (from UMRAO) at 14.5 GHz for the observation period 2007 July 24 - September 15.

4. Results

Figure 4 shows a Gaussian-smoothed count map in Galactic coordinates integrated over the observing period 2007 August 23 - 27 for photon energies over 100 MeV. In this period, AGILE detected gamma-ray emission from a position consistent with the quasar PKS 1510-089 at a significance level of 5.6-$\sigma$ as derived from a maximum likelihood analysis using the PKS 1510-089 radio position ($l = 351.29^\circ, b = 40.14^\circ$). During this period the source was located $\sim 50^\circ$ off the AGILE pointing direction. Thanks to the large field of view of AGILE, during this period, the satellite simultaneously also detected the gamma activity of the source Vela Pulsar ($l = 263.55^\circ, b = -2.79^\circ$), about 90 degrees from PKS 1510-089. In addition, the two sources were characterised by an almost equal angular distance from the AGILE pointing direction. This allowed us to obtain an estimate of average flux of PKS 1510-089 through a direct calibration with the flux of the Vela Pulsar. In this way, the average flux ($E > 100$ MeV) estimated for this first period was $(270 \pm 65) \times 10^{-8}$ photons cm$^{-2}$ s$^{-1}$. The reduced effective area and the consequently reduced count statistics for these large off-axis angles makes it difficult to create a light curve and an average energy spectrum.

Figure 4 shows a Gaussian-smoothed count map in Galactic coordinates integrated over the observing period 2007 August 27 - September 1 for photon energies higher than 100 MeV. In this period the satellite detected the source at a significance level of 10.6-$\sigma$. With the likelihood method, the best position for the gamma-ray emission above 100 MeV is $(l = 350.89^\circ, b = 40.34^\circ)$, with an average flux ($E > 100$ MeV) over the period of $(195 \pm 30) \times 10^{-8}$ photons cm$^{-2}$s$^{-1}$. The AGILE 95% maximum-likelihood contour level has a semi-major axis $a = 0.43^\circ$ and semi-minor axis $b = 0.09^\circ$. The overall AGILE error circle, taking both statistical and systematic effects into account, has a radius $r = 0.53^\circ$. During this period the source was observed at $35^\circ$ off-axis. In Fig. 3 the gamma-ray light curve for this period with a 1-day resolution, the R-band optical light curve as observed by the GASP of the WEBT for the observation period between 26 July and 11 September 2007, and the GASP radio light curve (from UMRAO) at 14.5 GHz for the observation period between 24 July and 15 September 2007 are reported. Figure 4 reports the average energy spectrum for this second period, when only three energy bins were taken into account for the fit: $100 \div 200$ MeV.
Fig. 5. Spectral Energy Distribution of PKS 1510-089 for the GRID observation period 28 August - 1 September 2007 (blue dots), including simultaneous GASP optical (red square) and radio (orange triangle) data and the 3-σ Super-AGILE upper limit. Non-simultaneous historical data (from 1969 to 2007) taken from NASA Extragalactic Database (NED) and Kataoka et al. (2007) over the entire electromagnetic spectrum are represented in dark grey and light grey, respectively.

MeV, 200 ÷ 400 MeV, 400 ÷ 1000 MeV. The energy bins 50 ÷ 100 MeV and 1000 ÷ 3000 MeV have not be used in the spectral analysis waiting for on-flight calibration finalization that will include these two energy channels.

A simple power-law model can fit the data. We obtain a photon index $\Gamma = 1.98 \pm 0.27$ with the weighted least squares method.

Super-AGILE observed PKS 1510-089 for a total on-source effective exposure time of 200 ks. The source was not detected above 5-σ by the Super-AGILE Iterative Removal Of Sources (IROS) applied to the image, in the 20–60 keV energy range. A 3-σ upper limit of 45 mCrab was obtained from the observed count rate by a study of the background fluctuations at the position of the source and a simulation of the source and background contributions with IROS.

Finally, in Fig. 5 the spectral energy distribution is shown for the GRID observation period 2007 August 28 - September 1, including simultaneous GASP optical and radio data and the 3-σ Super-AGILE upper limit. Also non-simultaneous historical data over the entire electromagnetic spectrum are represented.

5. Discussion

During the AGILE observation period, the PKS 1510-089 optical flux appears to be decreasing in the range $R \sim 15.5 \div 15.8$, following a bright state that reached at least $R = 15.0$ (see Fig. 4). The contemporaneous gamma-ray flux decrease of about a factor 3 suggests that the two flux variations may be correlated. In agreement with Kataoka et al. (2007), in order to model the spectral energy distribution we used a homogeneous one-zone synchrotron self-Compton (SSC) model, plus the contribution of external seed photons originating both from the accretion disc and the broad line region (BLR). We obtained a representative fit for the spectral energy distribution with input parameters similar to those chosen by Kataoka et al. (2007). We consider a relativistic moving spherical blob of radius $R = 2.5 \times 10^{16}$ cm and an electron energy distribution described by a double power law:

$$n_e(\gamma) = \frac{K \gamma_b^{-1}}{(\gamma/\gamma_b)^{\beta_1} + (\gamma/\gamma_b)^{\beta_2}}$$

for electron Lorentz factor $40 < \gamma < 4 \times 10^3$ with spectral indices pre- and post-break $p_1 = 2.0$ and $p_2 = 4.5$, a normalization factor $K = 80 \, \text{cm}^{-3}$ and the break energy Lorentz factor $\gamma_b = 400$. We assumed a magnetic field $B = 3 \, \text{Gauss}$ and a Doppler factor $\delta = 9$ for the blob.

In order to interpret our gamma-ray data, an accretion disc characterised by a blackbody spectrum with a luminosity of $10^{46}\,\text{erg s}^{-1}$ at 0.1 pc from the blob is assumed as the source of external target photons. The inverse Compton (IC) contribution from the disc is calculated up to the second order, but it is not enough to account for the high gamma-ray state observed by AGILE. The addition of the IC emission from a BLR, represented by a spherical layer extending between 0.1 pc and 0.4 pc from the central black hole, reprocessing a 10% of the irradiating continuum can explain the high state observed by AGILE compared to the historical EGRET observations (see Fig. 5), and it reflects on the different photon index obtained in the AGILE and EGRET observations. In this model, the SSC emission primarily contributes to the X-ray band, whereas the IC contribution from the BLR can explain the observed hard gamma-ray spectrum.

Acknowledgements. The AGILE Mission is funded by the Italian Space Agency (ASI) with scientific and programmatic participation by the Italian Institute of Astrophysics (INAF) and the Italian Institute of Nuclear Physics (INFN). This research has made use of the NASA/IPAC Extragalactic Database (NED) which is operated by the Jet Propulsion Laboratory, California Institute of Technology, under contract with the National Aeronautics and Space Administration.
