Algebraic and group treatments to nonlinear displaced number states and their nonclassicality features: A new approach

N Asili Firouzabadi, M K Tavassoly, and M J Faghihi

1. Introduction

Nowadays, nonclassical states of the radiation field have obtained a great deal of attention in various fields of research, such as quantum optics, quantum cryptography, and quantum communication.[11–7] These states may be generated through the conditional measurement techniques or the atom–field interactions in cavity QED.[8–10] and also may be revealed, for instance, in the Jaynes–Cummings model[11–18] and in the field of nonlinear coherent states[19–26] which naturally arise from the canonical (standard) coherent states.

The standard coherent state defined by

$$|\alpha\rangle = e^{-|\alpha|^2/2} \sum_{n=0}^{\infty} \frac{\alpha^n}{\sqrt{n!}} |n\rangle$$

is a quantum state which describes the radiation field, i.e., known as displaced vacuum states, |\alpha\rangle = \hat{D}(\alpha)|0\rangle, where \hat{D}(\alpha) = \exp(\alpha \hat{a} - \alpha^* \hat{a}^\dagger) is the well-known displacement operator in which \hat{a} and \hat{a}^\dagger are the bosonic annihilation and creation operators, respectively. Considering this idea, regarding the construction of coherent state, the displaced number states (DNSs) have been introduced by the displacement operator acting on the number state |n\rangle which are defined by |n, \alpha\rangle = \hat{D}(\alpha)|n\rangle.[27]

$$|\alpha, n\rangle = \exp\left(-\frac{|\alpha|^2}{2}\right) \times \left\{ \begin{array}{ll} N_1 \sum_{m=0}^{\infty} \sqrt{m!} (-\alpha^*)^m L_m^{n-m} (|\alpha|^2)^m |m\rangle, & m \leq n, \\ N_2 \sum_{m=0}^{\infty} \sqrt{m!} \alpha^m L_m^{m-n} (|\alpha|^2)^m |m\rangle, & m \geq n. \end{array} \right. \tag{1}$$

It has been shown that DNSs indicate several interesting nonclassicality features such as unusual oscillations in the photon number distribution interpreting as the interference in the phase space.[28]

On the other hand, nonlinear coherent states, which are known as a natural generalization of canonical coherent states (corresponding to simple harmonic oscillator) to f-deformed ones (associated with nonlinear oscillators),[19,20] can be considered as suitable candidates from which nonclassical light comes out.[29–33] It is worthwhile to mention that there are many generalized coherent states categorized in this special class of quantum states, which exhibit the nonclassicality features of light, i.e., ‘nonclassical’ light.[34–37]

Based on the above explanations, regarding the DNSs as well as the nonlinear coherent states, one may motivate to establishing a direct connection between DNSs and nonlinear coherent states, which leads to the concept of ‘nonlinear displaced number states’ (NDNSs). This idea has recently been introduced by de Oliveira et al.[38] In detail, in this attempt, the authors have paid attention to the forms of the standard coherent state

$$|\alpha\rangle = e^{-|\alpha|^2/2} \sum_{n=0}^{\infty} \frac{\alpha^n}{\sqrt{n!}} |n\rangle$$

and the nonlinear coherent state

$$|\alpha, f\rangle = N (|\alpha|^2)^{-1/2} \sum_{n=0}^{\infty} \frac{\alpha^n}{\sqrt{n!} |f(n)|^2} |n\rangle$$

(the latter has been defined by Man’ko et al.[20]). Then, in a simple and unsatisfactory comparison between the coefficients of coherent state, DNS and nonlinear coherent state, the
authors have manually inserted the nonlinearity function $f(n)$ into their DNSs in a special form, by which they proposed the states
\[ |\alpha, f, n \rangle = \exp \left( \frac{-|\alpha|^2}{2} \right) \times \begin{cases} 
\mathcal{N}_1 \sum_{m=0}^{\infty} \sqrt{\frac{m!}{[m]!}} (-\alpha^*)^{n-m} \hat{L}_{m}^{-m}(|\alpha|^2)|m\rangle, & m \leq n, \\
\mathcal{N}_2 \sum_{m=0}^{\infty} \sqrt{\frac{m!}{[m]!}} \alpha^{n-m} \hat{L}_{m}^{-m}(|\alpha|^2)|m\rangle, & m \geq n
\end{cases}
\] (2)
being called NDNSs by them. It seems that the above construction of NDNS in Ref. [38] is so artificial such that there may not be found any clear physical or even reliable mathematical reason for its basis. Hence, one may naturally seek a satisfactory method containing logical mathematical backgrounds and, if possible, enough physical motivations for the construction of the NDNSs. In this regard, we paper by modifying the definition of NDNSs in Ref. [38] we intend to outline a logical formalism from which NDNSs can be reasonably constructed. For this purpose, by recalling the nonlinear coherent states approach together with the displacement operator, an algebraic method through which the NDNSs are introduced, is presented. In addition, with the help of a particular class of Gilmore–Perelomov-type of SU(1,1) and a class of SU(2) coherent states, the NDNSs are defined via group-theoretical approach. Then, in each case, some of the well-known nonclassicality features are numerically evaluated.

The plan of this paper is as follows: In the next section, the NDNS is algebraically introduced. In Section 3, by considering two particular classes of coherent states, the NDNS is defined via group-theoretical approach. Section 4 deals with studying the nonclassicality signs of the obtained NDNSs through the Mandel parameter as well as the Wigner quasi-distribution function. Finally, Section 5 contains a summary and concluding remarks.

2. Nonlinear displaced number states: Algebraic approach

This section is devoted to the construction of the NDNSs via algebraic method. To reach this goal, it is necessary to introduce the generalized displacement operators $D_f(\alpha)$ by joining the nonlinear coherent state method and the standard displacement operator. So, the generalized displacement operator reads as $D_f(\alpha) = \exp(\alpha \hat{A}^\dagger - \alpha^* \hat{A})$, in which $\hat{A} = \hat{a} f(\hat{n})$ and $\hat{A}^\dagger = f(\hat{n}) \hat{a}^\dagger$ represent the nonlinear ($f$-deformed) annihilation and creation operators, respectively.\cite{[19],[20]} Now, the following communication relations are obviously satisfied
\[
[\hat{A}, \hat{A}^\dagger] = (\hat{n} + 1) f^2(\hat{n}) + \hat{a}^2(\hat{n}), \quad [\hat{A}, \hat{a}] = \hat{A}, \quad [\hat{A}^\dagger, \hat{a}] = -\hat{A}^\dagger,
\] (3)
where $f(\hat{n})$ is generally a Hermitian operator-valued function which depends on the number operator. The relation (3) clearly shows that the $f$-deformed displacement operator $D_f(\alpha)$ cannot be generally separated by the well-known Baker–Campbell–Hausdorff (BCH) formula (noticing that the BCH lemma is satisfied under specific conditions). This is due to the fact that, the commutation relation of $\hat{A}$ and $\hat{A}^\dagger$ is a complicated operator. In order to dispel this problem and to be able to use the generalized displacement operator on the number state, Roy and Roy\cite{[39]} gave a proposition and defined two new auxiliary operators as follows:
\[
\hat{B} = \frac{1}{f(\hat{n})} \hat{B} = \frac{1}{f(\hat{n})} \hat{a}, \quad [\hat{A}, \hat{B}] = [\hat{B}, \hat{A}^\dagger] = 1,
\] (4)
which has been also established in a general mathematical framework by Ali et al. in Ref. [34]. In other words, it should be declared that, incorporating the concept of nonlinear coherent states with the displacement operator is achieved only by making use of the above-mentioned auxiliary operators (since only by these new operators the necessary condition for BCH is satisfied). As a consequence of the latter relation, it may be observed that, by considering a special composition of the operators $\hat{A}$ and $\hat{B}$, the generators $[\hat{A}, \hat{B}^\dagger, \hat{B}^\dagger, \hat{A}^\dagger]$ and also $[\hat{B}, \hat{A}^\dagger, \hat{A}^\dagger, \hat{B}, \hat{I}]$ constitute the commutation relations of the Weyl–Heisenberg Lie algebra and the following relations clearly hold\cite{[35],[39]}
\[
\hat{B}^\dagger \hat{A}|n\rangle = f(n)|n\rangle, \quad [\hat{A}, \hat{B}^\dagger \hat{A}^\dagger] = \hat{A}, \quad [\hat{B}^\dagger, \hat{B}^\dagger \hat{A}] = -\hat{B}^\dagger.
\] (5)
As a result, two generalized displacement operators can be defined which are given by
\[
D_f'(\alpha) = \exp(\alpha \hat{A}^\dagger - \alpha^* \hat{B}),
\]
\[
= \exp \left( -\frac{|\alpha|^2}{2} \right) \exp(\alpha \hat{A}^\dagger) \exp(-\alpha^* \hat{B}),
\]
\[
D_f''(\alpha) = \exp(\alpha \hat{B}^\dagger - \alpha^* \hat{A}^\dagger)
\]
\[
= \exp \left( -\frac{|\alpha|^2}{2} \right) \exp(\alpha \hat{B}^\dagger) \exp(-\alpha^* \hat{A}^\dagger),
\] (7)
in which we have used the BCH formula. Now, by the action of two distinct displacement-type or generalized displacement operators defined in Eqs. (6) and (7) on the number state, the NDNSs are introduced in the following ways:
\[
|\alpha, f, n \rangle' = D_f'(\alpha)|n\rangle,
\]
\[
|\alpha, f, n \rangle'' = D_f''(\alpha)|n\rangle.
\] (9)
By substituting Eq. (6) into relations (8) and after some lengthy but straightforward manipulations, the explicit form of the NDNSs is given by
\[
|\alpha, f, n \rangle' = \exp \left( -\frac{|\alpha|^2}{2} \right) \times \begin{cases} 
\mathcal{N}_1' \sum_{m=0}^{\infty} \sqrt{\frac{[m]!}{[m]!}} (-\alpha^*)^{n-m} \hat{L}_{m}^{-m}(|\alpha|^2)|m\rangle, & m \leq n, \\
\mathcal{N}_2' \sum_{m=0}^{\infty} \sqrt{\frac{[m]!}{[m]!}} \alpha^{n-m} \hat{L}_{m}^{-m}(|\alpha|^2)|m\rangle, & m \geq n
\end{cases}
\] (10)
where $[f(n)] = f(n)f(n-1)\cdots f(1)$ with the conventional relation $[f(0)] = 1$,
\[
L_i^m(x) = \sum_{r=0}^{\infty} \frac{(k+i)!}{(l+r)!} \frac{(-x)^r}{r!}
\]
corresponds to the associated Laguerre polynomials and $\mathcal{N}_i^m, i = 1, 2,$ refers to the normalization factors which are given by
By looking deeply at the NDNSs obtained in Eqs. (10) and (12) and comparing them with the introduced NDNSs in Eq. (2), it is manifestly found that they are essentially different from each other by the term $|f(n)|!$. We would like to emphasize the fact that the nonlinear terms $|f(n)|!$ and $|f(m)|!$ are logically obtained in our introduced state while the term $|f(n)|!$ which is seen in Ref. [38] does not arise from a reasonable procedure, since the authors have manually entered this term in DNSs. It is also valuable to state that based on our formalism, many NDNSs can be easily constructed by using various nonlinearity functions associated with nonlinear oscillators as well as every solvable quantum systems (due to the simple relation $e_n = nf^2(n)$), refer to Refs. [35] and [36]. In the next section, by using the group-theoretical method, another class of NDNS with particular nonlinearity function $f(n)$ is acquired.

3. Nonlinear displaced number states: Group-theoretical approach

It is illustrated that, by considering the group algebra and paying attention to the fact that the construction of a unitary displacement operator with $\hat{A}$ and $\hat{A}^\dagger$ is possible through the particular nonlinearity functions associated with the specific physical systems, a few classes of nonlinear coherent states may be produced. Based on this fact, in the following, two types of NDNSs are introduced by using the group representation.

3.1. Gilmore–Perelomov-type of SU(1, 1) coherent states

Keeping in mind the approach of Man’ko et al. in Ref. [20], it is shown that, the (modified) trigonometric potential $V(x) = U_0 \tan^2(bx)$, in which $U_0$ is the strength of the potential and $b$ is its range, corresponds to the nonlinearity function $f_{GP}(n)$ which is given by

$$ f_{GP}(n) = \sqrt{\frac{hb^2}{2\mu\Omega}}(n + 2\lambda - 1). $$

In the latter relation, $\Omega$ is the frequency of the field, $\mu$ is the mass of the particle, $\lambda$ is related to the potential strength and is sometimes the so-called Bargmann index, which can take any positive integers or half integers, i.e., $\lambda = 1/2, 1, 3/2, \ldots$. Also, the parameter $b$ denotes the potential range and is obtained via the relation $\lambda(\lambda + 1) = 2\mu U_0/h^2b^2$. By substituting the nonlinearity function (14) into the $f$-deformed bosonic annihilation operator $\hat{A}_{GP} = \hat{a}f_{GP}(\hat{a})$, one may define the new operators

$$ \tilde{K}_- = \sqrt{\frac{2\mu\Omega}{hb^2}}\hat{A}_{GP}, \quad \tilde{K}_+ = \sqrt{\frac{2\mu\Omega}{hb^2}}\hat{A}_{GP}^\dagger, $$

and $\tilde{K}_0 = \lambda + n$ satisfying the commutation relations $[\tilde{K}_0, \tilde{K}_\pm] = \pm\tilde{K}_\pm$ and $[\tilde{K}_-\tilde{K}_+] = 2\tilde{K}_0$, which are the well-known $SU(1, 1)$ Lie algebra. Based on the group-theoretical construction for the Gilmore–Perelomov approach corresponding to discrete series representation of $SU(1, 1)$ group, the displacement operator reads as $\hat{D}_{GP}^\dagger(\alpha) = \exp(\xi\hat{K}_- - \xi^*\hat{K}_+)$. Now, by the action of $\hat{D}_{GP}^\dagger(\alpha)$ on the number state, the NDNSs associated with $SU(1, 1)$ group are given by

$$ |\xi, f, n\rangle_{\text{GP}} = \hat{D}_{GP}^\dagger(\alpha)|n\rangle = (1 - |\xi|^2)\lambda \sum_{m=0}^{\infty} \frac{(-\xi)^m \xi^n \sqrt{\sqrt{m!}} \left(1 - \frac{1}{\sqrt{m!}}\right)^n}{p!(n-p)!(m-p)!} \times \frac{|f_{GP}(n)|!|f_{GP}(m)|!}{|f_{GP}(p)|!^2} |n-p\rangle |m\rangle, $$

where we have used $\xi = \sqrt{hb^2/(2\mu\Omega)}\alpha$ and $\bar{\xi} = (\xi/|\xi|)\tan h\xi$ with $|\xi| < 1$. The condition $|\xi| < 1$ implies the fact that the phase space of the $SU(1, 1)$ coherent states is confined to the interior of the unit disk of the complex plane.
3.2. SU(2) coherent states

Another case of a physical potential, which can be equivalent to a nonlinearity function, is known as the modified Pöschl–Teller potential by relation \( V(x) = U_0 \tanh^2(ax) \) with \( U_0 \) and \( a \) as the depth and the range of well, respectively.\(^{41}\) This potential is related to a system that possesses a finite discrete spectrum. The corresponding nonlinearity function is of the form

\[
f_{SU(2)}(n) = \sqrt{\frac{\hbar a^2}{2\mu \Omega}}(2s + 1 - n),
\]

where \( \mu \) denotes the reduced mass of the molecule and \( s \) means the depth of well which is related to its range though the relation \( s(s + 1) = 2\mu U_0/\hbar^2 a^2 \). Considering the \( f \)-deformed bosonic annihilation operator \( \hat{A} = \hat{a} f_{SU(2)}(\hat{n}) \), the new operators, \( \mathcal{K}_- = \sqrt{2\mu \Omega}/(\hbar a^2)\mathcal{A}, \mathcal{K}_+ = \sqrt{2\mu \Omega}/(\hbar a^2)\mathcal{A}^\dagger \), and \( \mathcal{K}_0 = n - s \) may be defined with the commutation relations \([\mathcal{K}_0, \mathcal{K}_\pm] = \pm \mathcal{K}_\pm \) and \([\mathcal{K}_-, \mathcal{K}_+] = -2\mathcal{K}_0 \). Paying attention to the fact that the introduced operators clearly satisfy the SU(2) Lie algebra,\(^{42}\) the displacement-type operator corresponding to this group reads as \( \hat{D}_f^{SU(2)}(\alpha) = \exp(\eta \mathcal{K}_- - \eta^* \mathcal{K}_+) \) with \( \eta = \sqrt{\hbar a^2/(2\mu \Omega)} \alpha \). By the action of such a displacement operator on the number state, the new class of NDNSs associated with SU(2) group is obtained by the following relation

\[
|\gamma, f, n\rangle_{SU(2)}^{SU(2)} = \hat{D}_f^{SU(2)}(\alpha)|n\rangle
\]

\[
= \left( \frac{1}{1 + |\gamma|^2} \right)^s \sum_{m=0}^{\min[n,m]} \sum_{p=0}^{m} \frac{(-\gamma')^m \gamma^p m! [\frac{|\gamma|^2}{1 + |\gamma|^2}]^p}{p!(m - p)!} |n - p\rangle |m\rangle.
\]

where \( \gamma = (\eta^*/|\eta|) \tanh \eta \). It may be noted that the parameter \( s \) can get values 1/2, 1, 3/2, 2, …. Adding our obtained results in the two latter sections, it is seen that we have produced four different classes of NDNSs, all of which have been introduced by some reasonable procedures. Anyway, we are now in a position to examine the nonclassicality features of the obtained NDNSs in the continuation of the paper.

4. Nonclassical criteria

Since the nonclassical light is of special attention in the field of quantum optics and quantum information processing, in this section, we are going to study some of the well-known nonclassicality features of the introduced NDNSs. For this purpose, sub-Poissonian statistics as well as the negativity of Wigner distribution function are examined, numerically. Before proceeding, it ought to be mentioned that for evaluating any quantity for the NDNSs which have been produced by algebraic method (the relations (10) and (12)), a nonlinearity function should be chosen. For this purpose, we use the nonlinearity function \( f(n) = (1 + kn)^{-1} \), which has been considered in Ref. [38].

4.1. Sub-Poissonian statistics: Mandel parameter

This subsection deals with studying the quantum statistics of the states through the Mandel \( Q \)-parameter, which characterizes the photon statistics of light. This parameter has been

\[
Q = \frac{E_{\text{vac}} - 1}{\bar{P}},
\]

where \( E_{\text{vac}} \) is the expected number of photons in the vacuum state, and \( \bar{P} \) is the probability of having a photon in the state. For sub-Poissonian statistics, \( 0 < Q < 1 \), and for super-Poissonian statistics, \( Q > 1 \).

![Fig. 1. (color online) Variation of the Mandel parameter for different classes of NDNSs: (a) |\(\alpha, f, n\rangle, f_k(n) = (1 + kn)^{-1} \), and \( k = 0.07 \); (b) |\(\alpha, f, n\rangle, f_k(n) = (1 + kn)^{-1} \), and \( k = 0.07 \); (c) |\(\zeta, f, n\rangle, and \( n = 3 \); and (d) |\(\gamma, f, n\rangle \) and \( n = 1 \).](064204-4)
the photon statistics of the field becomes sub-Poissonian. \(\alpha\) increasing the value of \(\alpha\), this behavior is strengthened. Un-

Whenever \(-1 \leq Q < 0\) \((Q > 0)\) the statistics are sub-

Figure 1 shows the Mandel parameter for some different 

4.2. Wigner distribution function 

The Wigner function, known as the earliest quasi-

\[
W\left(\alpha, \alpha^*\right) = \frac{2}{\pi} \sum_{n=0}^{m} \left(-1\right)^n \left(\alpha^2 + |\beta|^2\right) \left| f(n) \right|^2 
\]

\[
\left\{ \begin{array}{ll}
N^\prime \sum_{m=0}^{\infty} \sqrt{\frac{\pi}{m!}} (-\alpha^*) \beta m^{-k} [f(m)]! \\
& \times L_m^{-m} \left( (\alpha^2 L_k^{-k}) |\beta|^2 \right)^2, \ m \leq n, \\
N^\prime \sum_{m=0}^{\infty} \sqrt{\frac{\pi}{m!}} \alpha \beta m^{-k} [f(m)]! \\
& \times L_m^{-m} \left( (\alpha^2 L_k^{-k}) |\beta|^2 \right)^2, \ m \geq n,
\end{array} \right.
\]

\[
W\left(\alpha, \alpha^*\right) = \frac{2}{\pi} \sum_{n=0}^{m} \left(-1\right)^n \left(\alpha^2 + |\beta|^2\right) \left| f(n) \right|^2 
\]

\[
\left\{ \begin{array}{ll}
N^\prime \sum_{m=0}^{\infty} \sqrt{\frac{\pi}{m!}} (-\alpha) \beta m^{-k} [f(m)]! \\
& \times L_m^{-m} \left( (\alpha^2 L_k^{-k}) |\beta|^2 \right)^2, \ m \leq n, \\
N^\prime \sum_{m=0}^{\infty} \sqrt{\frac{\pi}{m!}} \alpha \beta m^{-k} [f(m)]! \\
& \times L_m^{-m} \left( (\alpha^2 L_k^{-k}) |\beta|^2 \right)^2, \ m \geq n,
\end{array} \right.
\]

Similarly, the Wigner function associated with NDNSs of 

\[
W_{\text{GP}}\left(\alpha, \alpha^*\right) = \frac{2}{\pi} \sum_{k=0}^{\infty} \left(-1\right)^k \left(\alpha^2 + |\beta|^2\right)^{2k} 
\]

\[
W_{\text{SU}(2)}\left(\alpha, \alpha^*\right) = \frac{2}{\pi} \sum_{k=0}^{\infty} \left(-1\right)^k \left(\alpha^2 + |\beta|^2\right)^{2k} 
\]

negative values; a fact that is called ‘nonclassicality feature’. 

The Wigner function associated with any quantum state can be 

where \(|n, \alpha\rangle = D(\alpha)|n\rangle\) is the displaced number state intro-

\[
\sum_{n=0}^{\infty} \left(-1\right)^n \left(\alpha^2 + |\beta|^2\right)^{2k} \left| f(n) \right|^2 
\]

\[
\sum_{k=0}^{\infty} \left(-1\right)^k \left(\alpha^2 + |\beta|^2\right)^{2k} \left| f(n) \right|^2 
\]

\[
\sum_{k=0}^{\infty} \left(-1\right)^k \left(\alpha^2 + |\beta|^2\right)^{2k} \left| f(n) \right|^2 
\]
In Figs. 2, we have plotted the Wigner distribution function of the NDNSs obtained in relations (10), (12), (15), and (17) for the same chosen parameters as mentioned in Fig. 1. Figures 2(a)–2(d) indicate clearly the negativity of Wigner function in some finite regions of phase space, which implies the fact that the introduced NDNSs are ‘nonclassical’. It is also valuable to state that, by comparing quantitatively Fig. 2(a) with Figs. 2(b)–2(d), it is seen that the amount of the negativity of the Wigner function (the depth of this nonclassicality feature) in Fig. 2(a) is nearly 10 times greater than the others. In other words, the strength of nonclassicality of the state in Eq. (10) is more visible than the other states in Eqs. (12), (15), and (17).

Fig. 2. (color online) Variation of the Wigner distribution function for the NDNSs similar to Fig. 1.

5. Summary and conclusion

In this paper, by modifying the formalism of NDNSs presented in Ref. [38], we have introduced four distinct classes of NDNSs through algebraic and group treatments. For this purpose, by considering the DNSs together with nonlinear coherent states approach, two distinct classes of NDNSs were reasonably obtained via an algebraic treatment. In addition, by using a special class of Gilmore–Perelomov-type of SU(1,1) and a class of SU(2) coherent states (group approach), two other NDNSs were also introduced. Then, in order to study the nonclassicality features of the introduced states, sub-Poissonian statistics by evaluating Mandel parameter and the variation of Wigner quasi-probability distribution function associated with the obtained NDNSs were numerically examined. The presented results showed that the NDNSs exhibit sub-Poissonian statistics (nonclassical behavior) in a finite region. Also, as another appearance of the nonclassicality signs of the NDNSs, it was observed that the Wigner function is also negative in some areas of phase space. This means that the NDNSs can be considered as a good candidate for nonclassical light.

Acknowledgments

The authors would like to thank the referees for their helpful comments which clarified the content of the paper.
