Impact of Microbial Application on Growth & 
Development of *Dalbergia latifolia* & *Dalbergia sissoo* 
under Nursery Condition

Abstract

In the present study, a pot culture experiment was carried out on *Dalbergia latifolia* (Roxb) and *Dalbergia sissoo* for which 30 days old seedlings were developed from freshly collected seeds and subsequently supplemented with previously screened 2 phosphate solubilizing fungi and 2 Rhizobacterial broth of 7 days old, individually as well as in combination. The experimented plants were inoculated for 120 days at 30 days interval. Data recorded for plant height, biomass, leaf area, leaf no., branch no. and other physiological growth parameters RGR, NAR, LAR, Q1 and R/S. Growth analysis revealed that, *Aspergillus niger* and co-inoculation of selected microbes may be useful for successful establishment of *D. latifolia* & *D. sissoo* in nursery condition and help in producing quality planting materials.

Keywords: *D. latifolia*; *D. sissoo*; Phosphate solubilizing fungi; *Rhizobium*; Growth parameters

Introduction

The forest tree species belonging to Dalbergia are important timber trees, valued for their decorative and often fragrant wood, rich in aromatic oils Thurlough et al. [1], Vasudeva et al. [2] *Dalbergia latifolia* (Roxb) Family- Fabaceae, a large glabrous tree a single stem with characteristic smells, grey bark, thin with irregular short cracks, exfoliating in fibrous longitudinal flakes Parrota [3], Trup [4]. It is distributed in Bihar, Bundelkhand and Central India (Figure 1). Quality of having a long cylindrical bole, high strength and high density. The high quality wood properties make this species highly valuable and great demand. Hence, facing problem of depletion in population Raghava Swami et al. [5]. Besides wood demand it has great medicinal properties due to tannin which is being used for leprosy and worm Kirtikar & Basu [6]. It is slow growing and prone to jungle fire which also promotes its depletion in the natural forest. Hence, prioritization of large scale production and plantation is required Sujatha et al. [7].

*Dalbergia sissoo* is important plantation tree species and useful for afforestation program due to excellent coppicing properties. This species is endowed with many medicinal properties Ahmad et al. [8]. Hence, its large scale propagation & plantation is needed for the point of huge demand as well as environmental concern. Soil is composite system and inherent with many microbes including bacteria and fungi. Their population depends upon all multifarious condition also. Most of the tropical soil are “P” fixing and do not make available. This mineral content to the medicinal plant. Hence an additional dosage of “P” is required to fulfill the plant demand. To save the cost of chemical fertilizers as well to get rid of its ill effect over plant health, an alternative as bio-fertilizer is required. Many fungi and bacteria are reported to have capability to solubilize the bonded form of “P” content White law [9]. It may happen due to secondary metabolites and for enzymes Holford (1997). The application of such types of organism either alone or in
combination with the other useful organism especially nitrogen fixing make a suitable and worthy combination to help plants for microbial leaching and subsequent uptake Lee & Bressan [10]; Chen et al. [11].

In the present study, both the legume tree species are (one) facing problem of slow growth (D. latifolia) and (second) high demand (D. sissoo) were taken into consideration to develop a nursery technology so that a quality planting material could obtain. Quality material of any tree species will certainly be useful for the large scale plantation program which can save fertility and produce healthy plant products and fulfill the demand.

Materials and Methods

Present experiment was carried out during April-August, 2016 in the experimental field of Regional Plant Resource Centre, Bhubaneswar, Odisha, India. The experiment was done in poly bags containing 5.5 kg red soil. Pot soil was fumigated with 1% formalin for 48 hrs prior to the experiment. Deep brown colored flat seeds were decapsulated and sown in presaturated poly bags. Seeds were germinated in the poly bags. Two *Rhizobium*

Results and Discussion

Significant Increase in growth parameters of *D. sissoo* and *D. latifolia* seedlings over uninoculated control was indicative of the potential effect of these inoculants. *Aspergillus niger* is observed to be effective inoculants for *D. latifolia* influencing the shoot height (57.33±16.3cm), dry biomass (8.69±5.3 g), no. of leaves (70.33±21.7) (Table 1), RGR (0.061d⁻¹) & LAR (0.58 m²g⁻¹) (Table 2). *Aspergillus kanagawaensis* showed significant difference in leaf area (3591.33±88.6 mm²), dry biomass of root (5.76±1.0 g) and Quality index (0.258) (Tables 1 & 2) in *D. latifolia*. *Rhizobium* sp.-2 inoculated *D. latifolia* shows highest root length (39.67±15.0cm) and root shoot ratio (0.72) (Figure 2). The combination of *Rhizobium* sp.-2 and *Aspergillus kanagawaensis* in equal proportions was the most effective inoculants for NAR (0.10 g.m⁻².d⁻¹) (Table 2) in *D. latifolia*.

Where, RGR: Relative Growth Rate; NAR: Net Assimilation Rate; LAR: Leaf Area Ratio; QI: Quality Index; R/S= Root Shoot Ratio.

Similarly, in *D. sissoo*, *Aspergillus niger* was effective for the shoot height (94.33±8.5cm), *Rhizobium sp.-1* was momentous in root length (29.67±3.1cm) (Table 3), NAR (0.05 g.m⁻².d⁻¹) and R/S (0.35) (Table 4). *Rhizobium sp.-2* supplemented plantlets showed highest no of branch (4.67±0.6), dry shoot biomass (8.58±1.2g) & RGR (0.060d⁻¹). *Aspergillus niger* co-inoculated with *Rhizobium sp.-1&2* were found to be responsible for no of leaves (4.67±0.6) and Quality index (0.129) respectively. Combination of *A. kanagawaensis* and *Rhizobium sp.-2* resulted in highest leaf area (1741.33±35.8 mm²) and LAR (0.30 m².g⁻¹) (Tables 3 & 4).

In present experiment to evaluate the effective plant growth promoting ability of phosphate solubilizing fungi on forest trees was set up on Dalbergia sissoo & *Dalbergia latifolia* in pot culture condition which was supplemented with liquid cultures of phosphate solubilising fungi namely: *Aspergillus kanagawaensis, Aspergillus niger* and two *Rhizobium* sp-1 & 2 (Figure 3). The different fungal strains used in the present study were having phosphate solubilising potential tested in plate culture method in laboratory earlier. Previously, Odee et al. [18] recommended inoculation of liquid cultures for the healthy seedlings in the nursery conditions. This also helps in increasing fungal population in the rhizosphere and finally mineral solubilisation (Figure 4). In the present experiment revealed the effect of fungal and *Rhizobium* inoculation and their usefulness as bioinoculants for plant productivity. In present study *Aspergillus niger* individually and combined with *Rhizobium* sp-2 found to be most effective for overall plant growth promotion and establishment in both the experimented plants.

**Conclusion**

This experiment illustrates that the co-inoculation of *A. niger* and *Rhizobium* has improved nutrient status of the rhizospheric region. This combination brought about significant increase in the growth parameters of *Dalbergia* plants, suggesting their application for better growth and establishment.
