GELFAND-KIRILLOV DIMENSION OF COSEMISIMPLE HOPF ALGEBRAS

ALEXANDRU CHIRVASITU, CHELSEA WALTON, AND XINGTING WANG

Abstract. In this note, we compute the Gelfand-Kirillov dimension of cosemisimple Hopf algebras that arise as deformations of a linearly reductive algebraic group. Our work lies in a purely algebraic setting and generalizes results of Goodearl-Zhang (2007), of Banica-Vergnioux (2009), and of D’Andrea-Pinzari-Rossi (2017).

1. Introduction

Let $k$ be an algebraically closed field and all algebraic structures in this note will be $k$-linear. Recall from [14] that the Gelfand-Kirillov (GK-)dimension of a finitely generated, unital algebra $A$ is the growth measure defined by

$$
\text{GKdim } A = \limsup_{n \to \infty} \frac{\log(\dim V^n)}{\log n},
$$

where $V$ is a finite-dimensional generating subspace of $A$ containing $1_A$; this definition is independent of the choice of $V$ [14, page 14].

The typical techniques for computing the GK-dimension of an algebra involve Grobner basis methods or some other type of algebraic or representation-theoretic approach. But for the case that we examine here, i.e., when the algebra admits a well-behaved coalgebra structure, we can compute its GK-dimension using corepresentation-theoretic methods instead. Namely, given a finitely generated, cosemisimple Hopf algebra $H$ we consider the invariant $(R_+(H), d_H)$ used in [3]; here, $R_+(H)$ is the Grothendieck semiring for the category of finite-dimensional $H$-comodules and $d_H$ is the dimension function on $R_+(H)$. We first establish that if $H$ is finitely generated, then its GK-dimension depends only on $(R_+(H), d_H)$ [Proposition 2.7]. Then, our main result verifies that if $H$ is a deformation of a linearly reductive group $G$ in the sense that there is an isomorphism between two pairs $(R_+(H), d_H)$ and $(R_+(G), d_G)$ [Definition 2.1, Remark 2.2], then the GK-dimension of $H$ equals the dimension of $G$ as an algebraic variety [Theorem 2.9].

Our results are related to the fact if $\phi : H \to H'$ is a morphism of cosemisimple Hopf algebras that induces a semiring isomorphism $\phi_+ : R_+(H) \xrightarrow{\sim} R_+(H')$, then $\phi$ is a Hopf algebra isomorphism; see, e.g., [3, Lemma 5.1]. But we do not require such a map $\phi$ here to get $\text{GKdim } H = \text{GKdim } H'$; instead we just require map $R_+(H) \xrightarrow{\sim} R_+(H')$ that preserves dimension.

We introduce necessary terminology and verify the results mentioned above in Section 2. Then, we discuss in Section 3 how our main theorem compares to previous results on the growth of cosemisimple Hopf algebras by Goodearl-Zhang [12], by Banica-Vergnioux [3], and by D’Andrea-Pinzari-Rossi [8]. We also compute in Section 3 the GK-dimensions of Dubois-Violette and Launer’s and Mrozinski’s universal quantum groups [11, 16] using Theorem 2.9.

Key words and phrases. cosemisimple Hopf algebra, Gelfand-Kirillov dimension, Grothendieck semiring, linearly reductive algebraic group.
2. Terminology and Main Result

Throughout this section, let $H$ be a cosemisimple Hopf algebra. We write $\tilde{H}$ for the set of isomorphism classes $\{[S_\alpha]\}_\alpha$ of simple $H$-comodules $S_\alpha$; sometimes we abuse notation and write $\tilde{H}$ for the corresponding index set $\{\alpha\}$. Note that $\{[S_\alpha]\}_\alpha$ is a basis for the Grothendieck ring $R(H)$ as a free abelian group. The trivial $H$-comodule will be denoted by $1$. We also write $\leq_\oplus$ to denote direct summand. Now we discuss the invariant $(R_+(H), d_H)$ mentioned in the Introduction.

Definition 2.1. The measured Grothendieck semiring of $H$ is the pair $(R_+(H), d_H)$ where

- $R_+(H)$ is the Grothendieck semiring of the category of finite-dimensional $H$-comodules; and
- $d_H : R_+(H) \to \mathbb{N}$ is the $k$-vector space dimension function on $R_+(H)$.

We write $(R_+, d)$ if $H$ is understood.

If $H'$ is another cosemisimple Hopf algebra, then $(R_+(H), d_H)$ is isomorphic to $(R_+(H'), d_{H'})$ if there is a semiring isomorphism $f : R_+(H) \to R_+(H')$ so that $d_H([S_\alpha]) = d_{H'}(f([S_\alpha]))$ for all $[S_\alpha] \in \tilde{H}$.

Remark 2.2. Recall that the Hopf algebra $O(G)$ of regular functions on an affine algebraic group $G$ is cosemisimple if and only if $G$ is linearly reductive [1 Section 4.6] which in turn is equivalent to $G$ being reductive in characteristic 0 (see e.g. [17 Appendix to Chapter 1] and the references therein). We write $(R_+(G), d_G)$ for the measured Grothendieck semiring of $O(G)$.

Being cosemisimple, $H$ decomposes as the direct sum of its simple subcoalgebras. Because we are working over an algebraically closed field, the latter are matrix coalgebras necessarily of the form $M_\ell(\mathbb{k})^*$ for various ranks $0 < \ell < \infty$. In short, we obtain a decomposition

$$H = \bigoplus_{\alpha \in \tilde{H}} C_\alpha, \text{ for } C_\alpha \cong (M_{\dim S_\alpha}(\mathbb{k}))^*.$$  \hspace{1cm} (2.3)

Here, there are no multiple copies of any simple subcoalgebra in $H$ in the decomposition above; see, e.g., [13 Theorem 11.2.13(v)]. If one chooses a subspace $V$ of $H$ of the form

$$V = \bigoplus_{\alpha \in F} C_\alpha, \text{ for some finite subindex set } F \subseteq \tilde{H},$$  \hspace{1cm} (2.4)

then $V^n \subseteq H$ has the following representation-theoretic characterization.

Lemma 2.5. Take $V$ to be a subspace of $H$ as in (2.4). Then,

$$V^n = \bigoplus_{\beta \in F_n} C_\beta, \text{ where } F_n := \left\{ \beta \in \tilde{H} \mid S_\beta \leq_\oplus \left( \bigoplus_{\alpha \in F} S_\alpha \right)^\otimes n \right\}.$$  

Proof. Our goal is to show that $V^n$ and $(\bigoplus_{\alpha \in F} S_\alpha)^\otimes n$ have the same simple $H$-comodule direct summands; we do so by showing that they are the same as those for the $H$-comodule $V^\otimes n$.

Towards the goal, we recall the notion of the support of an $H$-comodule. For any finite-dimensional $H$-comodule $M$ with structure map $\rho : M \to M \otimes H$, we denote by $C(M)$ the unique minimal subspace of $H$ satisfying $\rho(M) \subseteq M \otimes C(M)$; we call $C = C(M)$ the support of the $H$-comodule $M$. By [19 Theorem 3.2.11(c)], $C$ is a finite-dimensional subcoalgebra of $H$. Since $H$ is cosemisimple, so is $C$, and hence, $C^*$ is semisimple. This implies that $M$, as a module over $H^*$, is a direct sum of the simple modules appearing as direct summands of $H^*/\text{Ann}_{H^*}(M) \cong C^*$. By [19 Corollary 3.2.6], there is a one-to-one correspondence between $C^*$-submodules of $M$ and...
C-subcomodules of $M$. So, $M$ is the direct sum of the simple $C$-comodules, i.e, $M$ is the coradical $C(M)_0$ of its support $C = C(M)$. Therefore, two $H$-comodules with the same support must have the same simple $H$-comodule direct summands.

Now it suffices to show that the $H$-comodules $V$ and $\bigoplus_{\alpha \in \mathcal{F}} S_\alpha$, and the $H$-comodules $V^{\otimes n}$ and $V^n$, have the same support. The first statement holds by (2.4) as $C_\alpha \cong (S_\alpha)^{\otimes \dim S_\alpha}$ as $H$-comodules. For the second statement, note the multiplication map $\mu_n : V^{\otimes n} \rightarrow V^n$ is a surjective $H$-comodule map, which induces an injective coalgebra map $C(V^n) \hookrightarrow C(V^{\otimes n})$. Since $V^n$ is a subcoalgebra of $H$, we have $C(V^n) = V^n$. Moreover, the $H$-comodule structure on $V^{\otimes n}$ is given by

$$H^{\otimes n} \xrightarrow{\Delta_n} H^{\otimes n} \otimes H^{\otimes n} \xrightarrow{1 \otimes \mu_n} H^{\otimes n} \otimes H.$$ 

Since $\Delta(V) \subset V \otimes V$, so we get $C(V^{\otimes n}) \subseteq \mu_n(V^{\otimes n}) = V^n$. Therefore, we have

$$C(V^{\otimes n}) \subseteq \mu_n(V^{\otimes n}) = V^n = C(V^n) \subseteq C(V^{\otimes n}).$$

This implies $V^{\otimes n}$ and $V^n$ share the same support. \qed

The result below is an immediate consequence of Lemma 2.5 and (2.3).

**Corollary 2.6.** Retaining the notation of Lemma 2.5. For representatives $S_\beta$ of $[S_\beta] \in \hat{H}$, we have that

$$\dim V^n = \sum_{\beta \in F_n} (\dim S_\beta)^2.$$ \qed

Now we obtain the following result.

**Proposition 2.7.** The Gelfand-Kirillov dimension of a finitely generated, cosemisimple Hopf algebra $H$ only depends on its measured Grothendieck semiring.

**Proof.** By the “local finiteness” property of coalgebras [15, Theorem 5.1.1], we can always choose a finite-dimensional subcoalgebra of $H$ so that it contains a finite vector space $V$ that generates $H$ as an algebra and that $1 \in V$ (i.e., the trivial $H$-comodule $1$ is a direct summand of $V$). Further, we can take $V$ of the form (2.4).

Note that the simple $H$-comodule index $F_n$ of $V^n$ in Lemma 2.5 is uniquely determined by the Grothendieck semiring structure of $H$; indeed, $\beta$ belongs to $F_n$ if and only if

$$\left( \sum_{\alpha \in \mathcal{F}} [S_\alpha] \right)^n = [S_\beta] + x$$

for some $x \in R_+$. The conclusion now follows from Corollary 2.6 and the definition of GK-dimension since $\dim V^n$ can be calculated by using the measure $d_H$ on all of the $[S_\beta]$’s that belong to $F_n$. \qed

We now apply the discussion above to Hopf algebras obtained as certain deformations of the Hopf algebra $O(G)$ in Remark 2.2.

**Definition 2.8.** Let $G$ be a linearly reductive algebraic group. A cosemisimple Hopf algebra $H$ is said to be a $G$-deformation if $R_+(H) \cong R_+(G)$. If, further, $(R_+(H), d_H) \cong (R_+(G), d_G)$, then $H$ is said to be a quantum function algebra on $G$.

The main result of this note is given below.
Theorem 2.9. Let $G$ be a linearly reductive algebraic group and let $H$ be a finitely generated, quantum function algebra on $G$ in the sense of Definition 2.8. Then, we have that

$$\text{GKdim } H = \dim G,$$

where the latter is the dimension of $G$ as an algebraic variety.

Proof. By Proposition 2.7, it is enough to prove this for $H = \mathcal{O}(G)$ itself. Recall from [14, Theorem 4.5(a)] that the GK-dimension of a finitely generated, commutative algebra coincides with its classical Krull dimension. Moreover, $\mathcal{O}(G)$ is finitely generated as $G$ is affine, and the classical Krull dimension of an algebra of regular functions on an algebraic variety is simply the dimension of that variety.

3. Examples and Previous Results

In this section, we highlight special cases of Theorem 2.9. We specialize to the case when $k$ has characteristic 0 throughout the section, since the requirement that an algebraic group be linearly reductive is rather strong in positive characteristic. Indeed, in characteristic $p > 0$ the only linearly reductive affine algebraic groups are extensions of tori by finite groups of order coprime to $p$; see [18].

The next few results take place in the same general setting, which we now recall briefly. Take:

- $G$, a semisimple, connected, simply connected algebraic group;
- $\mathfrak{g}$, the Lie algebra of $G$; and
- $q$ is a nonzero scalar. If $q$ is a root of unity of order $\ell$, then we assume that $\ell$ is odd, and coprime to 3 when $\mathfrak{g}$ contains a $G_2$-component.

Recall that we can define a $q$-deformed version $U_q(\mathfrak{g})$ of the enveloping algebra $U(\mathfrak{g})$; see, e.g., [7, Chapter 9]. One can then define the Hopf subalgebra $\mathcal{O}_q(G)$ of the Hopf dual $U_q(\mathfrak{g})^\circ$ by first passing to an integral form $\Gamma(\mathfrak{g})$ of $U_q(\mathfrak{g})$, and then using matrix coefficients for integral representations (i.e., $\Gamma(\mathfrak{g})$-modules which are free $\mathbb{Q}[q^{\pm 1}]$-modules of finite rank). The category of finite-dimensional $\mathcal{O}_q(G)$-comodules is equivalent to the (monoidal) category of type 1 finite-dimensional $U_q(\mathfrak{g})$-modules whose weights lie in the lattice corresponding to a maximal torus of $G$. We refer the reader to [10] and [5, Sections I.7 and III.7] for further details.

Proposition 3.1. Retain the hypotheses above. Then, $\text{GKdim } \mathcal{O}_q(G) = \dim G$.

Proof. First, assume that $q$ is not a root of unity. Then, [7, Theorem 10.1.14] implies that $\mathcal{O}_q(G)$ is cosemisimple. Moreover, [7, Proposition 10.1.16] implies that $\mathcal{O}_q(G)$ is a quantum function algebra on $G$. Thus, Theorem 2.9 applies to obtain that $\text{GKdim } \mathcal{O}_q(G) = \dim G$.

Next suppose $q$ is a root of unity of order $\ell$ as above. The $\ell = 1$ case holds by Remark 2.2.

Remark 3.2. The case when $q \in \mathbb{C}^\times$ is transcendental over $\mathbb{Q}$ recovers a result of Goodearl-Zhang [12]. Namely, [12, Theorem 0.1] shows that $\mathcal{O}_q(G)$ is Auslander-regular and Cohen-Macaulay, and its GK-dimension is as in Theorem 2.9 (and also equal to its global dimension).

The next three remarks pertain to connected, simply connected, compact real Lie groups $G$. 

Remark 3.3. A weight-theory-based argument appears in work of Banica-Vergnioux [3] for a particular case of Theorem 2.9. Namely, [3, Theorem 2.1] computes the GK-dimension for algebras of regular functions on connected, simply connected, compact, real Lie groups. This is done in unitary language, working with the maximal compact subgroups of such linear algebraic groups.

Remark 3.4. The result in Remark 3.3 was then extended by different methods, close in spirit to what we achieve here, to representative functions on arbitrary compact groups (i.e., regular functions on classical reductive groups) in work of D’Andrea-Pinzari-Rossi [8, Corollary 3.5].

Remark 3.5. In the real, unitary setting, Proposition 3.1 also recovers the main result of [6]. This is proved under the additional assumption that \( q \) is positive and \( q < 1 \) in order to make use of an appropriate \(^*-\)structure on \( O_q(G) \).

We also emphasize that Theorem 2.9 can be applied to \( G \)-deformations more general that those arising in Proposition 3.1, such as cosemisimple multi-parameter deformations of \( O(G) \). For instance, in the cosemisimple case, Takeuchi’s two-parameter deformations of \( GL(2) \) [20] are a subclass of the quantum groups discussed in Example 3.9 below.

Now we turn our attention to the growth of the \( SL(2) \)-deformations and the \( GL(2) \)-deformations studied in [4] and [16], respectively. To begin, we need the result below.

Lemma 3.6. Let \( H \) and \( K \) be two finitely generated, cosemisimple Hopf algebras, and suppose that there exists an isomorphism \( f : R_+(H) \to R_+(K) \) between their Grothendieck semirings. If there is a class \( [X] \in R_+(H) \) such that \( \text{dim} \ X > \text{dim} \ f(X) \), then \( \text{GKdim} \ H = \infty \).

Proof. Since \( X^\otimes n \) and \( f(X)^\otimes n \) have the same number of simple factors, we get that

\[
\text{length} \ X^\otimes n = \text{length} \ f(X)^\otimes n \leq \text{dim} \ f(X)^\otimes n = (\text{dim} \ f(X))^n.
\]

On the other hand, there is a simple \( H \)-comodule \( S_n \), which is a direct summand \( X^\otimes n \), with

\[
(\text{length} \ X^\otimes n)(\text{dim} \ S_n) \geq \text{dim} \ X^\otimes n = (\text{dim} \ X)^n.
\]

Hence, \( \text{dim} \ S_n \geq (\text{dim} \ X/\text{dim} \ f(X))^n \). Now we have that

\[
\text{GKdim} \ H \geq \limsup_{n \to \infty} \frac{\log(\text{dim} \ X^n)}{\log n} \geq \text{Cor. 2.6} \geq \limsup_{n \to \infty} \frac{\log(\text{dim} \ S_n)^2}{\log n} \geq \limsup_{n \to \infty} \frac{2n}{\log n} \log \left( \frac{\text{dim} X}{\text{dim} f(X)} \right),
\]

and from the hypothesis that \( \text{dim} \ X > \text{dim} \ f(X) \) we obtain the desired result. \( \square \)

Remark 3.7. Lemma 3.6 is analogous to both [9, Proposition 2.8] and [2, Proposition 6.1]. The latter is phrased in an analytic setting for compact quantum groups satisfying an amenability condition that is, in general, weaker than polynomial or even sub-exponential growth (see e.g. [8, Theorem 4.6]). On the other hand, [9, Proposition 2.8] is phrased in terms of a monoidal functor between categories of comodules over Hopf algebras (that are not necessarily cosemisimple) rather than for morphisms of Grothendieck semirings.

Example 3.8. Let \( V \) be an \( d \)-dimensional vector space and a matrix \( E \in GL_d(\mathbb{C}) \) encoding a bilinear form on \( V \). The quantum automorphism group \( B(E) \) was introduced in [11] and its comodule theory is studied in [4].

It is shown in [1, Theorem 1.2] that each \( SL(2) \)-deformation [Definition 2.8] is isomorphic to \( B(E) \), for some \( E \in GL_d(\mathbb{C}) \) such that the solution to \( q^2 + \text{tr}(E^T E^{-1})q + 1 = 0 \) is generic, that is, \( q \) equal to \( \pm 1 \) or a non-root of unity. In fact, the quantized coordinate ring \( O_q(SL(2)) \) is
cosemisimple if and only if \( q \) is generic; see Remark 2.2 [13, Section 4.2.5], and the discussion in [41, Section 5]. According to [4, Theorem 1.1], the category of \( B(\mathbb{E}) \)-comodules is equivalent to that of \( O_q(SL(2)) \) as monoidal categories (i.e., there exists a monoidal Morita-Takeuchi equivalence) for \( q \in \mathbb{C}^\times \) satisfying \( q^2 + \text{tr}(E^T E^{-1})q + 1 = 0 \).

Restricting our attention to the case when \( B(\mathbb{E}) \) is cosemisimple (or, when it is monoidally Morita-Takeuchi equivalent to \( O_q(SL(2)) \) for \( q \) generic) the proofs of results mentioned above makes it clear that \( V \) maps to the fundamental 2-dimensional \( O_q(SL(2)) \)-comodule under a semiring isomorphism,

\[
f : R_+(B(\mathbb{E})) \xrightarrow{\sim} R_+(O_q(SL(2))).
\]

Since \( \dim V = d \) and \( \dim f(V) = 2 \), we obtain that \( \text{GKdim} B(\mathbb{E}) = \infty \) for \( d > 2 \) by Lemma 3.6. On the other hand, we get that \( \text{GKdim} B(\mathbb{E}) = \dim SL(2) = 3 \) when \( d = 2 \) by Theorem 2.9.

This extends, in the case when \( B(\mathbb{E}) \) is cosemisimple, the result that \( \text{GKdim} B(\mathbb{E}) < \infty \) if and only if \( d = 2 \), obtained as part of [21, Theorem 0.3].

**Example 3.9.** Similarly, there are \( GL(2) \)-deformations \( G(\mathbb{E}, \mathbb{F}) \) introduced and studied in [16] that are defined by \( E, F \in GL_d(\mathbb{C}) \) so that \( F^T E^T EF = \lambda I \) for \( \lambda \in \mathbb{C}^\times \). We have that \( G(\mathbb{E}, \mathbb{F}) \) and \( O_q(GL(2)) \) are monoidally Morita-Takeuchi equivalent for \( q \in \mathbb{C}^\times \) satisfying

\[
q^2 - \sqrt{\lambda - 1}\text{tr}(E^T E^{-1})q + 1 = 0.
\]

[16, Theorem 1.1]. If, further, \( q \) is generic then \( R_+(G(\mathbb{E}, \mathbb{F})) \cong R_+(O_q(GL(2))) \) [16, Theorem 1.2]. Recall that \( O_q(GL(2)) \) is cosemisimple if and only if \( q \) is generic; see Remark 2.2 [13, Section 11.5.4], and the discussion in [16, Section 4].

Now restricting our attention to the case when \( G(\mathbb{E}, \mathbb{F}) \) is cosemisimple, \( \text{GKdim} G(\mathbb{E}, \mathbb{F}) = \infty \) for \( d > 2 \) by Lemma 3.6 and \( \text{GKdim} B(\mathbb{E}) = \dim GL(2) = 4 \) when \( d = 2 \) by Theorem 2.9.
