Abstract  
A polynomial form is established for the off-shell CHY scattering equations proposed by Lam and Yao. Re-expressing this in terms of independent Mandelstam invariants provides a new expression for the polynomial scattering equations, immediately valid off-shell, which makes it evident that they yield the off-shell amplitudes given by massless $\phi^3$ Feynman graphs. A CHY expression for individual Feynman graphs, valid even off shell, is established through a recurrence relation.
1 Introduction

Cachazo, He and Yuan (CHY) [1–3] have shown that the scattering equations, originally introduced by Fairlie and Roberts [4], describe the kinematics of massless particles in an arbitrary space-time dimension, $D$, by proposing remarkable formulae for tree amplitudes, which have been proved for $\phi^3$ theory and for gauge theory [5]. In a subsequent paper [6], we showed how to re-express these in terms of a polynomial form for the scattering equations. Here we show how to write this polynomial form so that it is valid when the external particles are off shell, by expressing it in terms of the independent Mandelstam variables associated with a particular cyclic ordering of the external particles, rather than the set of Mandelstam variables for all possible channels and orderings used in [6]. A particular use for these new off-shell polynomial scattering equations is in establishing recurrence relations and we apply them to establish CHY formulae for individual off-shell Feynman diagrams. These formulae for individual diagrams may help illuminate the underlying structure of the CHY formalism.

Consider $N$ massless particles, labelled by $a \in A = \{1, 2, \ldots, N\}$, with momenta, $k_a, a \in A$, which are on-shell, $k_a^2 = 0$, and satisfy momentum conservation, $\sum_{a \in A} k_a = 0$. Introduce a variable $z_a \in \mathbb{C}$ for each $a \in A$. Then the scattering equations are the $N$ equations

$$f_a(z, k) = 0, \quad a \in A,$$

where

$$f_a(z, k) = \sum_{b \in A \setminus \{a\}} \frac{k_a \cdot k_b}{z_a - z_b}.$$  \hspace{1cm} (1.1)

This system of $N$ equations is Möbius invariant, and consequently the functions $f_a$ satisfy three identities,

$$\sum_{a \in A} f_a(z, k) = 0; \quad \sum_{a \in A} z_a f_a(z, k) = 0; \quad \sum_{a \in A} z_a^2 f_a(z, k) = 0,$$  \hspace{1cm} (1.2)

so that only $N - 3$ are linearly independent. They are equivalent [6] to the $N - 3$ polynomial scattering equations $\hat{h}_m(z, k) = 0$, where

$$\hat{h}_m(z, k) = \sum_{S \subset A, |S| = m} k_S^2 z_S, \quad 2 \leq m \leq N - 2,$$  \hspace{1cm} (1.3)

the sum is over all $N!/m!(N - m)!$ subsets $S \subset A$ with $m$ elements, and

$$k_S = \sum_{b \in S} k_b, \quad z_S = \prod_{a \in S} z_a, \quad S \subset A.$$  \hspace{1cm} (1.4)

We shall refer to the $\hat{h}_m(z, k), 2 \leq m \leq N - 2$, as the scattering polynomials. In terms of these, the CHY formula for the sum of planar tree amplitudes in $\phi^3$ is

$$A_N = \oint \frac{1}{\prod_{m=2}^{N-2} \hat{h}_m(z, k)} \prod_{a < b} (z_a - z_b) \prod_{a \in A} \frac{dz_a}{(z_a - z_{a+1})^2} \bigg/ d\omega,$$  \hspace{1cm} (1.5)
where \( dw = dz_idz_jdz_k/(z_i-z_j)(z_j-z_k)(z_k-z_i) \) is the Möbius invariant measure corresponding to fixing \( z_1, z_2, z_3 \), and the integral encircles the zeros of \( \hat{h}_m(z, k) \), \( 2 \leq m \leq N - 2 \). Taking \( z_1 \to \infty, z_2 = 1, z_N = 0 \), we have

\[
A_N = \oint_{z_{N-1}} \frac{1}{z_{N-1}} \prod_{m=1}^{N-3} \frac{1}{h_m(z, k)} \prod_{a \leq b \leq N-1} (z_a - z_b) \prod_{a=2}^{N-2} \frac{z_a dz_{a+1}}{(z_a - z_{a+1})^2}.
\]  

(1.6)

where

\[
\hat{h}_m(z, k) = \lim_{z_1 \to \infty} \hat{h}_{m+1}/z_1,
\]

(1.7)

and the integration contour now encircles the zeros of \( \hat{h}_m(z, k) \), \( 1 \leq m \leq N - 3 \), and amounts to a sum over those zeros, of which there are \((N - 3)!)\). Using the polynomial form of the equation is less singular and more stable for numerical calculations in particular. Note that the polynomials \( \hat{h}_m \) are invariant under simultaneous permutations of the momenta, \( k_a \), and the variables, \( z_a \), whereas the integral depends on the specific choice of the ordering of the momenta, \( k_1, k_2, \ldots, k_N \), and to get the complete tree amplitude one has to sum over the possible orderings.

The definition (1.3) of \( \hat{h}_m \) involves the \( 2^N - 2N - 2 \) Mandelstam invariants but, given momentum conservation and the massless condition, just \( \frac{1}{2}N(N - 3) \) of these can be taken to be independent, provided that \( N - 1 \leq D \). We can re-express \( \hat{h}_m \) in terms of an independent set of invariants but not while maintaining its manifest permutation symmetry. We can pick an independent set of momenta as follows. Given the specified order of the momenta, \( k_1, k_2, \ldots, k_N \), consider consecutive sets,

\[
[I, J] = \{a : I \leq a \leq J\}, \quad 1 \leq I \leq J < N,
\]

(1.8)

There are \( \frac{1}{4}N(N-1) \) independent invariants, \( k_a^2 \), if we do not impose the on-shell condition, \( k_a^2 = 0, 1 \leq a \leq N \). Imposing that condition leaves the \( \frac{1}{4}N(N - 3) \) invariants, \( k_a^2 \), \( 1 \leq I < J < N \). In section 2, using \( k_a^2 = 0 \), we show that \( \hat{h}_m \) can be rewritten as

\[
\tilde{h}_m = \sum_{1 \leq I < J < N \atop (I, J) \neq (1, N-1)} k_a^2 (z_I - z_{I-1})(z_J - z_{J+1})\Pi_{[I,J]^o}^{m-2} \quad 2 \leq m \leq N - 2,
\]

(1.9)

where \( I - 1 \) is identified with \( N \) when \( I = 1 \), \( [I, J]^o \) is the complement of \( \{I - 1, I, J, J + 1\} \) in \( A \), and \( \Pi_{V}^0 \) is the symmetric function,

\[
\Pi_{V}^0 = \sum_{i_1 < i_2 < \cdots < i_n} z_{i_1}z_{i_2} \cdots z_{i_n}
\]

(1.10)

where \( V \subset A \) and \( n \leq |V| \). Thus, \( \Pi_{V}^0 = 1 \) and \( \Pi_{V}^{[0]} = \Pi_{V}^{[V]} = \prod_{i \in V} z_i \).

We use (1.9) to define \( \hat{h}_m \) as the off-shell polynomial form of the scattering equations, using (1.3) only on shell. Note that \( \hat{h}_m = \hat{h}_m \) in general only if \( k_a^2 = 0, a \in A \). Both \( \hat{h}_m \), \( 2 \leq m \leq N - 2 \), and the value of the integral expression (1.5) for \( A_N \) only involve the consecutive
invariants, \( k^2_{[I,J]} \), \( 1 \leq I < J < N \). This implies that, if we replace \( \hat{h}_m \) with \( \tilde{h}_m \) in (1.5), the integral

\[
\mathcal{A}_N = \oint \frac{1}{N-2} \prod_{m=2}^{N-2} h_m(z, k) \prod_{a<b} (z_a - z_b) \prod_{a \in A} (z_a - z_{a+1})^2 \frac{dz_a}{d\omega} ,
\]

(1.11)
gives the sum of planar tree diagrams for massless \( \phi^3 \) theory, even when the external momenta are off shell.

To show this, note that if the momenta, \( k_a, 1 \leq a \leq N \), satisfy momentum conservation, but are not necessarily massless, take another set of momenta, \( \ell_a, 1 \leq a \leq N \), satisfying momentum conservation, and such that \( \ell^2_{[I,J]} = k^2_{[I,J]} \), \( 1 \leq I < J < N \), and \( \ell^2_a = 0, 1 \leq a \leq N \). Then \( \tilde{h}_m \) as defined by (1.9) is the same for \( \{ k_a \} \) and for \( \{ \ell_a \} \). For \( \{ \ell_a \} \), but not \( \{ k_a \}, \tilde{h}_m \) as defined by (1.9) is the same as \( \hat{h}_m \) as defined by (1.3). Then, for \( \hat{h}_m \) with momenta \( \{ \ell_a \} \), (1.5) gives a sum of planar tree diagrams, each of which is a product of propagators \( 1/\ell^2_U \), where \( U \) is a consecutive subset of \( A \). Hence, this equals the corresponding product of propagators \( 1/k^2_U \). It follows that (1.11) gives the sum of planar diagrams with the off-shell momenta.

In section 2, we also show that the off-shell scattering equations derived in this way, \( \tilde{h}_m = 0 \), with \( \tilde{h}_m \) as in (1.9), are the polynomial form of the off-shell scattering equations proposed by Lam and Yao [7].

In section 3, as an application of these off-shell scattering equations we establish CHY integrals associated for individual Feynman tree diagrams using an off-shell recurrence relation. Associating as usual the momentum \( k_a \) and complex variable \( z_a \) with the \( a \)-th external leg of an individual Feynman diagram, \( \Delta \), we define the corresponding integrand by first associating a cross-ratio with each internal line or propagator of the diagram, in the way originally introduced by Koba and Nielsen [8]. Thus,

\[
u_{I,J} = \left( z_I - z_J \right) \left( z_{I-1} - z_{J+1} \right) / \left( z_I - z_{J+1} \right) \left( z_{I-1} - z_J \right) , \]

(1.12)
and taking \( u_\Delta \) to be the product of such cross-ratios for the \( N-3 \) propagators of the diagram. The corresponding integral is then

\[
\mathcal{A}_N^\Delta = \oint \frac{1}{u_\Delta} \prod_{1 \leq a < b \leq N} (z_a - z_b) \prod_{a=1}^{N} dz_a \prod_{m=2}^{N-2} \frac{1}{h_m} \prod_{m=2}^{N-2} h_m \left/ d\omega , \right.
\]

(1.13)
where the contour encircles the zeros of \( \tilde{h}_m \). Using an off-shell recurrence relation, we show that \( A_N^A \) is the product of factors \( 1/k_{I,J}^2 \) for the \( N-3 \) propagators, and so equals the value of the Feynman diagram for \( \phi^3 \) field theory. [For other work on associating CHY expressions to individual Feynman diagrams see [9–13].]

## 2 Off-Shell Scattering Equations

To rewrite \( \hat{h}_m \), as defined by (1.3), in terms of independent invariants we need to write each \( k_S^2 \) in terms of \( k_{[I,J]}^2 \), \( 1 \leq I \leq J < N \). First note that, for any three vectors \( K_1, K_2, K_3 \),

\[
(K_1 + K_3)^2 = (K_1 + K_2 + K_3)^2 - (K_1 + K_2)^2 - (K_2 + K_3)^2 + K_1^2 + K_2^2 + K_3^2. \tag{2.1}
\]

From this it follows by induction that, for vectors \( K_i, 1 \leq i \leq 2n - 1 \),

\[
(K_1 + K_3 + \cdots + K_{2n-1})^2 = K_{1,2n-1}^2 - K_{1,2n-2}^2 - K_{2,2n-1}^2 + K_{1,2n-3}^2 + K_{2,2n-2}^2 + K_{3,2n-1}^2 + \cdots + K_2^2 + K_3^2 + \cdots + K_{2n-1}^2
\]

\[
= \sum_{1 \leq i \leq j \leq 2n-1} (-1)^{i-j}K_{i,j}^2, \tag{2.2}
\]

where \( K_{i,j} = K_i + K_{i+1} + \cdots + K_j \).

If \( S \subset A \) and \( \overline{S} \) denotes the complement of \( S \) in \( A \), then \( k_S^2 = k_{\overline{S}}^2 \). Just one of \( S \) and \( \overline{S} \) does not contain \( N \). So, writing \( A^* = \{1, 2, \ldots, N-1\} \), we can rewrite (1.3) as

\[
\hat{h}_m(z, k) = \sum_{S \subset A^* \atop |S| = m} k_S^2 z_S + \sum_{S \subset A^* \atop |S| = m} k_{\overline{S}}^2 z_{\overline{S}}, \quad 2 \leq m \leq N - 2. \tag{2.3}
\]

Now, we can write a given \( S \subset A^* \) as the union of consecutives subsets \( S_r, r = 1, 3, \ldots, 2n-1 \), of \( A^* \), and denote the indices between \( S_{2r-1} \) and \( S_{2r+1} \) by \( S_{2r} \), \( 1 \leq r \leq n-1 \), which is nonempty. Taking \( K_r = k_{S_r} \),

\[
k_S^2 = \sum_{1 \leq i \leq j \leq 2n-1} (-1)^{i-j}k_{S_{i,j}}^2, \tag{2.4}
\]

where \( S_{i,j} = S_i \cup S_{i+1} \cup \ldots S_j \) is also consecutive. Substituting (2.4) into (2.3), if \( 1 \leq I < J < N \), and the consecutive subset \([I, J] \subset A^*\) occurs as \( S_{i,j} \), with \( i, j \) both odd, \( z_S \) contains a factor \( z_{Iz,J} \) and \( \overline{z}_S \) contains a factor \( z_{I-1z,J+1} \), while if \( i, j \) both even, \( z_S \) contains a factor \( z_{Iz,J} \) and \( \overline{z}_S \) contains a factor \( z_{I-1z,J+1} \); if \( i \) is odd and \( j \) is even \( z_S \) contains a factor \( z_{Iz,J} \) and \( \overline{z}_S \) contains a factor \( z_{I-1z,J} \), while if \( i \) is even and \( j \) is odd it is the other way round. If \( i \) and \( j \) have different parity, the term has a negative sign. For example, with \( N = 7, S = \{1, 4, 5\} \), we have \( S_1 = \{1\}, S_2 = \{2, 3\}, S_3 = \{4, 5\} \), and \( S_{1,2} = \{1, 2, 3\} = S_{[I,J]} \) with \( I = 1, J = 3 \) and \( z_{1z4} \) is a factor of \( z_S \), while \( z_7z_3 \) is a factor of \( \overline{z}_S \) (where \( z_{-1} \) is cyclically identified with \( z_7 \)).

In \( \hat{h}_m \), each of the terms \( z_{Iz,J}, z_{I-1z,J+1}, -z_{I-1z,J}, -z_{Iz,J+1} \) occurs multiplied by each of the
products of \( m - 2 \) distinct factors taken from \([I, J]^o\), yielding \( \tilde{h}_m = \tilde{h}_m \), where

\[
\tilde{h}_m = \sum_{1 \leq I < J < N \\ (I, J) \neq (1, N-1)} k_{[I, J]}^2 (z_I - z_{I-1})(z_J - z_{J+1}) \Pi_{[I, J]}^{m-2} \Pi_{[I, J]}^{m-1} \quad 2 \leq m \leq N - 2,
\]

provided that \( k_{a}^2 = 0 \) for each \( a \in A \). Relaxing this condition, we take the vanishing of (2.5) as the definition of the off-shell polynomial scattering equations because, inserted in (1.11), they give the correct off-shell tree diagrams, as argued in the Introduction.

For example,

\[
\begin{align*}
N &= 4 \\
\tilde{h}_2 &= s_{12} z_{14} z_{23} + s_{23} z_{21} z_{34}, \\
N &= 5 \\
\tilde{h}_2 &= s_{12} z_{15} z_{23} + s_{12} z_{15} z_{34} + s_{23} z_{21} z_{34} + s_{23} z_{21} z_{45} + s_{34} z_{32} z_{45}, \\
\tilde{h}_3 &= s_{12} z_{15} z_{23} z_{4} + s_{12} z_{15} z_{34} z_{2} + s_{23} z_{21} z_{34} z_{5} + s_{23} z_{21} z_{45} z_{3} + s_{34} z_{32} z_{45} z_{1},
\end{align*}
\]

where \( z_{ab} = z_a - z_b \) and \( s_{a_1, \ldots, a_m} = k_{23}^2 \{a_1, \ldots, a_m\} \). The cyclic symmetry of \( \tilde{h}_2, \tilde{h}_3 \) is evident if it is noted that \( s_{123} = s_{45} \), etc.

To fix the Möbius invariance, let \( z_1 \to \infty, z_2 = 1, z_N = 0 \), and now write

\[
h_m = \lim_{z_1 \to \infty} \tilde{h}_{m+1}/z_1 = \sum_{J=2}^{N-2} k_{[1, J]}^2 (z_J - z_{J-1}) \Pi_{[1, J]}^{m-1} - \sum_{J=3}^{N-1} k_{[2, J]}^2 (z_J - z_{J+1}) \Pi_{[2, J]}^{m-1} \\
+ \sum_{3 \leq I < J < N} k_{[I, J]}^2 (z_I - z_{I-1})(z_J - z_{J+1}) \Pi_{[I, J]}^{m-2} \Pi_{[I, J]}^{m-1},
\]

1 \( \leq m \leq N - 3 \), where \([I, J]^o = [I, J]^o \cap A', A' = \{2, 3, \ldots, N\}\).

For the simplest case, \( N = 4 \), writing \( z_3 = x, \) and \( s_{ij} = k_{[i, j]}^2 \), we only have \( h_1 \),

\[
h_1 = s_{12} (1 - x) - s_{23} x,
\]

whereas the ‘on-shell’ polynomial \( h_1 \), defined by (1.7), is

\[
\hat{h}_1 = s_{12} + s_{13} x
\]

Since \( s_{12} + s_{13} + s_{23} = k_1^2 + k_2^2 + k_3^2 + k_4^2 \), \( \hat{h}_1 = h_1 \) on shell, and

\[
\int \frac{dx}{x(1-x)h_1} = -\frac{1}{s_{12}} - \frac{1}{s_{23}}, \quad \int \frac{dx}{x(1-x)\hat{h}_1} = -\frac{1}{s_{12}} + \frac{1}{s_{12} + s_{13}},
\]

agreeing only on shell.

With the definition (2.5) of the off-shell scattering equations, \( \tilde{h}_m = 0 \), we can reverse our calculation to determine how (1.3) must be modified to hold off shell. To do this we must
remove the terms involving $k_a^2$ in the expression (2.4) of $k_S^2$ in terms of the independent invariants $k_{[I,J]}^2$:

$$k_S^2 = \sum_{1 \leq i \leq j \leq 2n-1 \mid \delta_{i,j} \geq 1} (-1)^{i-j} k_{S_{i,j}}^2 + \sum_{a \in S \setminus a-1,a+1 \notin S} k_a^2 + \sum_{a \in S \setminus a-1,a+1 \notin S} k_a^2. \quad (2.11)$$

It follows that if we modify (1.3) to read

$$\tilde{h}_m = \sum_{S \subseteq A \mid |S| = m} \sigma_S z_S, \quad 2 \leq m \leq N - 2, \quad (2.12)$$

where

$$\sigma_S = k_S^2 - \sum_{a \in S \setminus a-1,a+1 \notin S} k_a^2 - \sum_{a \in S \setminus a-1,a+1 \notin S} k_a^2. \quad (2.13)$$

(2.12) is equivalent to (2.5) as a definition of the off-shell polynomial scattering equations. Note that, if $|S| = 1$ or 0, $\sigma_S$, as defined by (2.13), equals 0.

To see how the original form of the scattering equations (1.1) should be modified in order to work off shell, we reverse the line of argument that was used in the derivation of the polynomial form in [6]. Consider

$$\tilde{h}(z) = \sum_{m=2}^{N-2} (-z)^{N-m-2} \tilde{h}_m$$

$$= \sum_{m=0}^{N-2} (-z)^{N-m-2} \sum_{S \subseteq A \mid |S| = m} z_S \left[ k_S^2 - \sum_{a \in S \setminus a-1,a+1 \notin S} k_a^2 - \sum_{a \in S \setminus a-1,a+1 \notin S} k_a^2 \right], \quad \text{using } k_S^2 = k_S^2,$$

$$= \prod_{c \in A} (z - z_c) \sum_{a,b \in A \setminus a \neq b} \frac{k_a \cdot k_b}{(z - z_a)(z - z_b)} + \sum_{m=0}^{N-2} (-z)^{N-m-2} \sum_{S \subseteq A \mid |S| = m} \rho_S z_S$$

where

$$\rho_S = \sum_{a \notin S} k_a^2 - \sum_{a \in S \setminus a-1,a+1 \notin S} k_a^2 - \sum_{a \in S \setminus a-1,a+1 \notin S} k_a^2$$

$$= - \sum_{a-1,a+1 \notin S} k_a^2 + \sum_{a \notin S} k_a^2 + \sum_{a \notin S} k_a^2 - \sum_{a \in S \setminus a-1,a+1 \notin S} k_a^2$$

$$= - \sum_{a-1,a+1 \notin S} k_a^2 + \sum_{a,a+1 \notin S} k_a^2 + \sum_{a-1,a \notin S} k_a^2. \quad (2.14)$$
Thus
\[ h(z) \prod_{c \in A} (z_c - z)^{-1} = \sum_{a,b \in A, a \neq b} \frac{k_a \cdot k_b}{(z - z_a)(z - z_b)} - \sum_{a \in A} \frac{k_a^2}{(z - z_{a-1})(z - z_{a+1})} \]
\[ + \sum_{a \in A} \frac{k_a^2}{(z - z_{a-1})(z - z_{a})} + \sum_{a \in A} \frac{k_a^2}{(z - z_{a})(z - z_{a+1})} \]  
(2.15)

Thus the off-shell polynomial scattering equations are equivalent to the identical vanishing of the right hand side of (2.15). Since this only has single poles and vanishes for large \( z \), this is equivalent to the vanishing of its residue at each \( z = z_a \), that is to \( f_a(z,k) = 0, a \in A \), where
\[ f_a(z,k) = \sum_{b \neq a} \frac{k_a \cdot k_b}{z_a - z_b} - \frac{1}{2} \frac{k_{a-1}^2}{z_a - z_{a-2}} + \frac{1}{2} \left( \frac{k_{a-1}^2 + k_a^2}{z_a - z_{a-1}} \right) + \frac{1}{2} \left( \frac{k_{a}^2 + k_{a+1}^2}{z_a - z_{a+1}} \right) - \frac{1}{2} \frac{k_{a+1}^2}{z_a - z_{a+2}}. \]  
(2.16)

This is the form of the off-shell scattering equations proposed by Lam and Yao [7]. It follows from our discussion that they do indeed yield the correct off-shell amplitudes. [For other discussion of off-shell amplitudes see [14] and [15].]

The Möbius invariance of the system of off-shell scattering equations follows from the Möbius invariance of the condition that (2.15) vanish identically. It can also be verified directly on (2.16). Reflecting this invariance, \( f_a, a \in A \), satisfy the same relations (1.2) that the \( f_a, a \in A \), do.

### 3 Individual Feynman Diagrams

#### 3.1 An Example

As an example of the recurrence relation we will prove in subsection 3.3, we consider the \( N = 6 \) Mercedes diagram, \( M \), shown in Fig. 2a, where we take \( (z_1, z_2, z_3, z_4, z_5, z_6) = (\infty, 1, x, y, z, 0) \). Then the integral (1.13) takes the form
\[ \mathcal{A}_6^M = \oint_{h_1^6h_2^6h_3^6} \frac{(1 - y)(x - z)ydxdydz}{(x - y)zh_1^6h_2^6h_3^6}, \]  
(3.1)

where \( h_1^6, h_2^6, h_3^6 \) are the Möbius fixed scattering polynomials defined by (2.7) with \( N = 6 \),
\[ h_1^6 = s_{12}z_{23} - s_{23}z_{34} + s_{13}z_{34} - s_{234}z_{45} + s_{1234}z_{45} - s_{2345}z_5, \]
\[ h_2^6 = s_{12}z_{23}(z_4 + z_5) - s_{23}z_{34}z_5 - s_{23}z_{34}z_{45} - s_{234}z_{34}z_5 + s_{123}z_{34}(z_2 + z_5), \]
\[ - s_{234}z_{34}z_3 - s_{34}z_{23}z_5 + s_{1234}z_{45}z_3 - s_{2345}z_5(z_3 + z_4) \]
\[ h_3^6 = s_{12}z_{23}z_{45} - s_{45}z_{34}z_5 + s_{123}z_{34}z_5 - s_{234}z_{23}z_{45} + s_{1234}z_{34}z_5 - s_{2345}z_3z_{45}, \]

and the integral is round their common zeros.
In order to remove the pole of the integrand at \( z = 0 \), we replace \( h_2^6, h_3^6, \) by \( h_{(z_{(5)})}^6, h_{(z_{(6)})}^6 = h_3^6 \), where \( h_1^6(z) = h_3^6 - zh_2^6 + z^2h_4^6 \) is the \( z_1 \rightarrow \infty \) limit of (2.14). This introduces a Jacobian factor of \(-z\), to give

\[ A_6^M = -\oint_{h_6^6h_3^6h_2^6} \frac{(1-y)(x-z)y dydz}{(x-y)h_1^6h_2^6h_3^6}. \]  

(3.2)

The solutions of \( h_1^6 = h_2^6 = h_3^6 = 0 \) are solutions of \( h_1^6 = h_6^6(z) = h_3^6 = 0 \), while solutions of \( h_1^6 = h_2^6(z) = h_3^6 = 0 \) are either solutions of \( h_1^6 = h_2^6 = h_3^6 = 0 \) or have \( z = 0 \). From (A.8), we have \( z = 0, h_6^6(z) = s_{56}xy \) and this is cancelled by factors in the numerator so that we may write

\[ A_6^M = -\oint_{h_1^6h_2^6h_3^6} \frac{(1-y)(x-z)y dydz}{(x-y)h_1^6h_2^6h_3^6} \]

(3.3)

\[ = -\oint_{h_1^6h_2^6h_3^6} \frac{(1-y)(y-z)y dydz}{(x-y)h_1^6h_2^6h_3^6}, \]

using the global residue theorem. Now, from (A.8), at \( x = y \),

\[ h_1^{6|_{x=y}} = h_1^6, \quad h_2^{6|_{x=y}} = (y-z)h_2^6 - s_{34}(1-y)(z-y)z, \quad h_3^{6|_{x=y}} = yh_2^6, \]

(3.4)

where \( h_1^6, h_2^6 \), given explicitly in (A.4), are the scattering polynomials associated with the Feynman diagram, \( M' \), shown in Fig. 2b, \( h_5^5 = h_5^5 - zh_1^5 \), and so, performing the \( x \) integration,

\[ A_6^M = -\frac{1}{s_{34}} \oint_{h_5^5h_2^6h_1^5} \frac{dydz}{h_1^5h_2^6} = -\frac{1}{s_{34}} A_6^{M'}, \]

(3.5)

where \( A_6^{M'} \) is the amplitude associated with \( M' \). It straightforward to show

\[ A_6^{M'} = \frac{1}{s_{12}^6s_{56}^6}, \quad \text{and so} \quad A_6^M = -\frac{1}{s_{12}^6s_{34}^6s_{56}^6}. \]  

(3.6)

This example illustrates the techniques we shall use to establish a general recurrence relation. (For a further example, with \( N = 8 \), see Appendix B.) But before doing this we need to analyze the structure of the integrand in the next subsection.
3.2 Form of the Integrand

The sum of off-shell tree diagrams is given by (1.11), which can be rewritten

\[ A_N = \oint \Phi_N \prod_{d(a,b)\geq 2} (z_a - z_b) \prod_{m=2}^{N-2} \frac{1}{h_m} \prod_{a \in A} dz_a / d\omega, \tag{3.7} \]

where \( d(a,b) = \min(|a-b|, N-|a-b|) \), \( 1 \leq a < b \leq N \), and

\[ \Phi_N = \prod_{d(a,b)=2} (z_a - z_b) / \prod_{d(a,b)=1} (z_a - z_b). \tag{3.8} \]

We associate the individual Feynman diagram \( \Delta \) with the integral, \( A_N^\Delta \), obtained by replacing \( \Phi_N \) by \( 1/u_\Delta \), both of which are Möbius invariant,

\[ A_N^\Delta = \oint \frac{1}{u_\Delta} \prod_{1 \leq a < b \leq N} (z_a - z_b) \prod_{m=2}^{N-2} \frac{1}{h_m} \prod_{a \in A} dz_a / d\omega, \tag{3.9} \]

where \( u_\Delta \) is the product of the cross-ratios (1.12).

The product \( 1/u_\Delta \) has only simple poles in the variables \( z_a \), and these only occur at locations of the form \( z_a = z_b \) where \( |a-b| \neq 2 \). To see this is true, suppose \( \Delta \) has \( i_1 \) vertices with one internal leg (type 1), \( i_2 \) vertices with two internal legs (type 2), and \( i_3 \) vertices with three internal legs (type 3), so that total number of vertices, \( V = i_1 + i_2 + i_3 = N - 2 \). As each internal leg or propagator connects two vertices, the number of propagators, \( P = \frac{1}{2}(i_1 + 2i_2 + 3i_3) = N - 3 \). Thus

\[ i_3 = i_1 - 2, \quad i_2 = N - 2i_1. \tag{3.10} \]

As in Fig. 1, each propagator corresponds to a consecutive subset \( S = [I,J] \subset A \), where \( 1 \leq I < J < N \) (and to its complement, but choose the representative subset so that \( N \notin S \).

The graph has at least two type 1 vertices and we label the graph so that the legs 1, \( N \) meet at one of these vertices. Then each propagator corresponds to a consecutive subset of \([2, N-1]\), including \([2, N-1]\) itself, and we denote these subsets by \( S_i, 1 \leq i \leq N-3 \). They are such that, if \( S_i \cap S_j \neq \emptyset \), either \( S_i \subset S_j \), or \( S_j \subset S_i \). Thus, the propagator subsets, \( S_i \), are partially ordered: given a propagator \( S_{i_0} \), all the propagators \( S_j \supset S_{i_0} \) can be ordered into an ascending sequence, \( S_{i_0} \subset S_{i_1} \subset S_{i_2} \subset \ldots \subset [2, N-1] = S_{i_M} \), for some \( M \), with \( S_{i_k} \) meeting \( S_{i_{k+1}} \) at a vertex, \( 0 \leq k \leq M - 1 \).

At a type 1 vertex, external dlegs, \( I, I+1 \), meet to form the propagator \([I, I+1]\). Consider the vertex next above the propagator \([I, J]\) in the ascending sequence. If it is a type 2 vertex, either the external leg \( I-1 \) meets the propagator \([I, J]\) to form the propagator \([I-1, J]\), or the propagator \([I, J]\) meets the external leg \( J+1 \) to form the propagator \([I, J+1]\). If it is a type 3 vertex, the propagator \([I, J]\) meets the propagator \([J+1, K]\) to form the propagator \([I, K]\), for some \( I < J < K \).
The propagator \([I, J]\) is associated with a factor in \(1/u_{\Delta}\) given by the cross-ratio,

\[
\frac{1}{u_{I, J}} = \frac{(z_I - z_{I+1})(z_{I-1} - z_J)}{(z_I - z_J)(z_{I-1} - z_{I+1})}
\]  

(3.11)

The factor \((z_I - z_J)\) only occurs in the denominators of the cross-ratios associated with the potential propagators \([I, J]\) and \([I + 1, J - 1]\). Thus \((z_I - z_J)^{-2}\) cannot occur in the denominator unless both \([I, J]\) and \([I + 1, J - 1]\) actually are propagators, in which case \(I < J - 2\).

Taking \(S_{i_0} = [I+1, J-1]\), the next propagator, \(S_{i_1}\), in the ascending sequence from \(S_{i_0}\) cannot be \([I, J]\), because \([I, J]\) is not a consecutive set, and thus \([I, J]\) does not meet \([I + 1, J - 1]\) at a vertex. It follows that \([I, J] = S_{i_2}\), with either \(S_{i_1} = [I, J - 1]\) or \(S_{i_1} = [I + 1, J]\). The cross-ratios associated with \([I, J - 1]\) or with \([I + 1, J]\) both contain a factor of \((z_I - z_J)\) in the numerator, so that, whether \(S_{i_1} = [I, J - 1]\) or \(S_{i_1} = [I + 1, J]\), the product of cross-ratios for \(S_{i_0}, S_{i_1}\), and \(S_{i_2}\) only has a simple pole at \(z_I = z_J\). Since this does not occur as a pole in the cross-ratio associated with any other propagator, the integrand itself has at most a simple pole at \(z_I = z_J\).

The factor \((z_I - z_{I+2})\) only occurs in the denominator of the cross-ratio associated with \([I, I + 2]\). If this is a propagator, either \([I, I + 1]\) or \([I + 1, I + 2]\) must be in the sequence. The cross-ratios of each of these contains a factor of \((z_I - z_{I+2})\) in the numerator, so the product of the cross-ratios for all propagators does not contain a pole at \(z_I = z_{I+2}\). Similar considerations exclude poles at \(z_2 = z_N\) and \(z_1 = z_{N-1}\). It follows that the product of cross-ratios contains only simple poles and these are at \(z_a = z_b\), for some values of \(a, b\) satisfying \(|a - b| = 1\) or \(|a - b| > 2\). The latter poles are cancelled in the integrand of (1.13) leaving just \(i_1\) simple poles at positions \(z_I = z_{I+1}\) corresponding to the type 1 vertices.

### 3.3 Recurrence Relation

We now establish a recurrence relation for \(A_{N}^{\Delta}\), which we use to establish that it equals the corresponding Feynman diagram. Consider an \(N\)-point Feynman diagram, \(\Delta\), with possibly off-shell momenta, \(k_a\), and associated variables \(z_a, a \in A\), labeled so that the legs associated with \(z_3\) and \(z_4\) meet in a vertex. Fix Möbius invariance by setting \(z_1 \rightarrow \infty, z_2 = 1,\) and \(z_N = 0\), and write \(x = z_3, y = z_4\). Further consider the \((N - 1)\)-point diagram, \(\Delta'\), obtained by removing the \(z_3, z_4\) external legs of \(\Delta\), so that the propagator at which they join becomes an external leg and the external legs of \(\Delta'\) are labeled \(z_1, z_2, z_4, z_5, \ldots, z_N\), and the associated momenta are \(k_1, k_2, k_3 + k_4, k_5, \ldots, k_N\). [Note that \((k_3 + k_4)^2 \neq 0\) in general, even if \(k_a^2 \neq 0\) for \(1 \leq a \leq N\), so that an off-shell recurrence relation is needed.]

After fixing Möbius invariance, the amplitude associated with \(\Delta\) is given by

\[
A_{N}^{\Delta} = \oint h_1^N h_2^N \cdots h_{N-3}^N \frac{dx dy dz_5 \cdots dz_{N-1}}{h_1^N h_2^N \cdots h_{N-3}^N} \]  

(3.12)

where the suffix \(h_1^N h_2^N \cdots h_{N-3}^N\) on the integral indicates that it is taken round the common
zeros of $h^N_a$, $1 \leq a \leq N - 3$,

$$F^\Delta_N = \frac{1}{u_\Delta} \prod_{2 \leq a < b \leq N} (z_a - z_b), \quad (3.13)$$

and $h^N_m = \lim_{z_1 \to \infty} \tilde{h}^N_{m+1}/z_1$, the superscript $N$ indicating that these are the scattering polynomials associated to the $N$-point amplitude, with momenta, $k_1, \ldots, k_N$, and variables, $z_1, \ldots, z_N$ rather than the $(N - 1)$-point one, which we shall denote by $h^{N-1}_m$, with momenta, $k_1, k_2, k_3 + k_4, k_5, \ldots, k_N$, and variables, $z_1, z_2, z_4, z_5, \ldots, z_N$.

$$\Delta$$

The amplitude associated with $\Delta'$ is given by

$$A^\Delta'_{N-1} = \oint \prod_{a=5}^{N} \frac{dydz_5 \ldots dz_{N-1}}{h^N_{1-1}h^N_{2-1} \ldots h^N_{N-4}} \cdot F^\Delta'_{N-1} \cdot F^\Delta_N / (x-y)(1-z_5) \cdot (y-z_a) \cdot F^\Delta'_{N-1} + O(x-y), \quad (3.14)$$

The extra cross-ratio factor in $F^\Delta_N$ relative to $F^\Delta'_{N-1}$ corresponds to the propagator factor

$$\frac{(x-z_5)(1-y)}{(x-y)(1-z_5)} \quad (3.15)$$

and other factors from the product in (3.13) are $(1-z_5)$, $(x-z_6)$, $(x-u_a)$, $7 \leq a \leq N$, so that

$$F^\Delta_N = \frac{1-y}{x-y} \prod_{a=5}^{N} (y-z_a) \left[ F^\Delta'_{N-1} + O(x-y) \right]. \quad (3.16)$$

To establish the recurrence relation, as in subsection 3.1, it is useful to make use of the function $\tilde{h}_{(z)}$ introduced in (2.14), or rather its asymptotic form as $z_1 \to \infty$,

$$h_{(z)} = \lim_{z_1 \to \infty} \left( \tilde{h}^N_{(z)}/z_1 \right) = \sum_{m=1}^{N-3} (-z)^{N-m-3} h^N_{m}. \quad (3.17)$$

Replacing $h^N_1 h^N_2 \ldots h^N_{N-3}$ by $h^N_{1} h^N_{(z_5)} \ldots h^N_{(z_{N-1})} h^N_{(z_N)}$ in the denominator of (3.12) introduces...
a Jacobian factor of
\[
(-1)^{\frac{1}{2}N(N-1)} \prod_{5 \leq a < b \leq N} (z_a - z_b)
\]  
(3.18)
when the integral is evaluated at \( h_1^N = h_2^N = \ldots = h_{N-3}^N = 0 \), so that
\[
A_N^\Delta = (-1)^{\frac{1}{2}N(N-1)} \int_{h_1^N h_2^N \cdots h_{N-3}^N} F_N^\Delta \prod_{5 \leq a < b \leq N} (z_a - z_b) \frac{dz_N \cdots dz_{N-1}}{h_1^N h_{(z_1)}^N h_{(z_2)}^N \cdots h_{(z_N)}^N}. 
\]  
(3.19)

\( h_1^N, h_2^N, h_{(z_a)}^N, \ldots, h_{(z_N)}^N \) all vanish when \( h_1^N = h_2^N = \ldots = h_{N-3}^N = 0 \). Conversely, if \( h_1^N = 0 \) and \( h_{(z_a)}^N = 0, \ldots, h_{(z_N)}^N \) all vanish. Conversely, if \( h_1^N = 0 \) and \( h_{(z_a)}^N = 0, \ldots, h_{(z_N)}^N \) all vanish. From (3.19), we see that \( F_N^\Delta \) has a pole at \( x = y \) and, from subsection 3.2, we know that its other possible singularities are simple poles at \( z_{a-1} = z_a \), where \( 6 \leq a \leq N \). However we shall show that such poles are cancelled by a zero in \( F_N^\Delta \), and so they do not contribute to the integral. Assuming this to be the case, and using (3.16),
\[
A_N^\Delta = (-1)^{\frac{1}{2}N(N-1)} \int_{h_1^N h_{(z_1)}^N h_{(z_2)}^N \cdots h_{(z_N)}^N} \left[ F_N^\Delta + O(x - y) \right] \frac{1 - \frac{y}{x}}{x - y} \prod_{a=5}^N (y - z_a) 
\times \prod_{5 \leq a < b \leq N} (z_a - z_b) \frac{dz_N \cdots dz_{N-1}}{h_1^N h_{(z_1)}^N h_{(z_2)}^N \cdots h_{(z_N)}^N}. 
\]  
(3.20)

Now, the only pole of the integrand, other than where \( h_1^N = h_{(z_1)}^N = h_{(z_2)}^N = \ldots = h_{(z_N)}^N = 0 \), is at \( x = y \) and so, using the global residue theorem, we can replace \( h_{(z_a)}^N \) with \( x - y \) in the specification of the integration contour,
\[
A_N^\Delta = -(-1)^{\frac{1}{2}N(N-1)} \int_{h_1^N(x-y) h_{(z_1)}^N h_{(z_2)}^N \cdots h_{(z_N)}^N} F_N^{\Delta'} \frac{1 - \frac{y}{x}}{x - y} \prod_{a=5}^N (y - z_a) 
\times \prod_{5 \leq a < b \leq N} (z_a - z_b) \frac{dz_N \cdots dz_{N-1}}{h_1^N h_{(z_1)}^N h_{(z_2)}^N \cdots h_{(z_N)}^N} 
= (-1)^{\frac{1}{2}N(N-1)} \int_{h_1^N h_{(z_1)}^N h_{(z_2)}^N \cdots h_{(z_N)}^N} F_N^{\Delta'}(1 - \frac{y}{x}) \prod_{a=5}^N (y - z_a) 
\times \prod_{5 \leq a < b \leq N} (z_a - z_b) \frac{dy \cdots dz_N \cdots dz_{N-1}}{[h_1^N h_{(z_1)}^N h_{(z_2)}^N \cdots h_{(z_N)}^N]_{x=y}}, 
\]  
(3.21)
on performing the \( x \) integration. Now, using (A.7) and (A.8),
\[
h_1^N \big|_{x=y} = h_1^{N-1}, \quad h_{(z_a)}^N \big|_{x=y} = (y - z_a) h_{(z_a)}^{N-1}, \quad 6 \leq b \leq N, 
\]  
(3.22)
\[ A_\Delta^N = (-1)^{N+1} \int_{h_1^{(z_5)}h_N^{(z_N)}} F_N^{\Delta'} \left. \frac{1}{h_{(z_5)}} \right|_{x=y} (1-y)(y-z_5) \]
\[ \times \prod_{5 \leq a < b \leq N} (z_a - z_b) \frac{dydz_5...dz_{N-1}}{h_1^{N-1}h_{(z_a)}^{N-1}...h_{(z_N)}^{N-1}} \]  
\[ (3.23) \]

We can now replace \( h_1^{N-1}h_{(z_a)}^{N-1}...h_{(z_N)}^{N-1} \) with \( h_1^{N-1}h_2^{N-1}h_3^{N-1}...h_{N-4}^{N-1} \) and an appropriate Jacobian factor,

\[ A_\Delta^N = (-1)^{N+1} \int_{h_1^{N}h_{(z_a)}^{N}...h_{(z_N)}^{N}} F_N^{\Delta'} \left. \frac{1}{h_{(z_5)}} \right|_{x=y} (1-y)(y-z_5) \]
\[ \times \prod_{b=6}^{N} (z_5 - z_b) \frac{dydz_5...dz_{N-1}}{h_1^{N-1}h_2^{N-1}...h_{N-5}^{N-1}h_{N-4}^{N-1}} = -\frac{1}{s_{34}} A_\Delta^{N-1}, \]  
\[ (3.24) \]

where we have used (A.8)

\[ h_{(z_5)}^{N} \bigg|_{x=y} = (y-z_5)h_{(z_5)}^{N-1} + s_{34}(1-y)(z_5-y) \prod_{b=6}^{N} (z_b - z_5). \]  
\[ (3.25) \]

To complete the argument, we need to show that there are no contributions to the \( A_\Delta^N \) from poles that \( F_N^{\Delta'} \) may have at \( z_{a-1} = z_a \), for some \( 6 \leq a \leq N \). To consider the possible contribution to (3.19) from such a pole in \( F_N^{\Delta'} \), note, as in (3.16), that

\[ F_N^{\Delta'} = (-1)^{N-a} \frac{1}{z_{a-1} - z_a} \prod_{b=2 \atop b \neq a-1,a}^{N} (z_b - z_a) \left[ F_{N-1}^{\Delta''} + O(z_{a-1} - z_a) \right] \]
\[ = (-1)^{N-a} \frac{1}{z_{a-1} - z_a} \frac{1}{s_{a-1,a}} h_{(z_a)}^{N} \bigg|_{z_{a-1} = z_a} \left[ F_{N-1}^{\Delta''} + O(z_{a-1} - z_a) \right] \]  
\[ (3.26) \]

and \( h_{(z_a)}^{N} \) is one of the zero denominators in \( A_\Delta^N \), which demonstrates that this contribution to the integral vanishes.

From (3.24), we have the recurrence relation,

\[ A_\Delta^N = -\frac{1}{s_{34}} A_\Delta^{N-1}, \]  
\[ (3.27) \]

which shows by induction that \( A_\Delta^N \) equals the product of factors \( 1/h_{[I,j]} \) for each propagator, \( i.e. \) it equals the value of the Feynman diagram.

Since we know that (3.7) gives the sum of \( N \)-point planar Feynman diagrams, \( \Delta \) [5, 6], it
follows that the difference
\[ R_N = \Phi_N - \sum \frac{1}{u}\Delta \]  
(3.28)

must integrate to zero when \( \Phi_N \) is replaced by \( R_N \) in (3.7). For \( N \leq 7 \), we can find a convenient expression for \( R_N \) and verify that this integral vanishes. If this could be done for all \( N \), this would give a direct proof that the CHY integral (3.7) equals the sum of planar Feynman diagrams, as established in [5, 6].

**Appendix A  Identities**

We consider the off-shell scattering polynomials in variables, \( z_1, z_2, \ldots, z_N \), for an \( N \)-point amplitude with momenta, \( k_1, k_2, \ldots, k_N \). Using the formula (2.5) for \( \tilde{h}_N \) in the definition (2.14) of \( \tilde{h}_N(z) \),
\[ \tilde{h}_N^N = \sum_{m=2}^{N-2} \tilde{h}_m^N(-z)^{N-2-m} \]
\[ = \sum_{1 \leq I < J < N} k^2_{[I,J]} (z_I - z_{I-1})(z_J - z_{J+1}) \prod_{a \in [I,J]^0} (z_a - z) \]  
(A.1)

If we put \( z_a = z_{a-1} \), \( \tilde{h}_N(z) \) is related to the corresponding function \( \tilde{h}_N^{N-1} \) for an \( (N-1) \)-point amplitude, with momenta, \( k_1, k_2, \ldots, k_{a-2}, k_{a-1} + k_a, k_{a+1}, \ldots, k_N \), and associated variables, \( z_1, z_2, \ldots, z_{a-2}, z_a, z_{a+1}, \ldots, z_N \), by the equation,
\[ \tilde{h}_N(z) \big|_{z_a = z_a} = (z_a - z)\tilde{h}_N^{N-1} + s_{a-1,a} (z_{a+1} - z_a) (z_{a-2} - z_a) \prod_{b \neq a-2,a-1,a,a+1} (z_b - z), \]  
(A.2)
where \( s_{a-1,a} = \frac{k^2}{[a-1,a]} \). From this it follows that

\[
\begin{align*}
\tilde{h}_N(z_a) \bigg|_{z_{a-1}=z_a} &= s_{a-1,a} \prod_{b \neq a-1,a} (z_b - z_a), \\
\tilde{h}_N(z_b) \bigg|_{z_{a-1}=z_a} &= (z_a - z_b) \tilde{h}_{N-1}^{N-1}(z_b), \quad b \neq a - 2, a - 1, a, a + 1, \\
\tilde{h}_N(z_{a-2}) \bigg|_{z_{a-1}=z_a} &= (z_a - z_{a-2}) \tilde{h}_{N-1}^{N-1}(z_{a-2}) + s_{a-1,a} (z_{a+1} - z_a)(z_{a-2} - z_a) \prod_{b \neq a-2,a-1,a,a+1} (z_b - z_{a-2}), \\
\tilde{h}_N(z_{a+1}) \bigg|_{z_{a-1}=z_a} &= (z_a - z_{a+1}) \tilde{h}_{N-1}^{N-1}(z_{a+1}) + s_{a-1,a} (z_{a+1} - z_a)(z_{a-2} - z_a) \prod_{b \neq a-2,a-1,a,a+1} (z_b - z_{a+1}),
\end{align*}
\]

(A.3)

Above we have used gothic script for the polynomial \( \tilde{h}_{m-1}^{N-1}, 2 \leq m \leq N - 3 \), which differs from \( \tilde{h}_{m-1}^{N-1} \) in that the arguments of \( \tilde{h}_{m-1}^{N-1} \) are momenta \( k_1, k_2, \ldots k_{a-2}, (k_{a-1} + k_a), k_{a+1}, \ldots k_N \) with \( \sum_{a=1}^{N-1} k_a = 0 \), whereas \( \tilde{h}_{m-1}^{N-1} \) would have momenta \( k_a, 1 \leq a \leq N-1 \), with \( \sum_{a=1}^{N-1} k_a = 0 \). Thus to define \( \tilde{h}_{m-1}^{N-1} \) fully, one needs to specify the value of \( a \), designating which pair \( k_{a-1} + k_a \) is joined. In (3.4), \( a = 4 \), and the associated momenta and variables are \( k_1, k_2, k_3 + k_4, k_5, k_6 \) with \( z_1, z_2, z_4, z_5, z_6 \) so

\[
\begin{align*}
\tilde{h}_5^5 &= s_{12} z_{24} - s_{345} z_{45} + s_{56} z_{45} - s_{61} z_5, \\
\tilde{h}_5^6 &= s_{12} z_{24} z_5 - s_{345} z_{24} z_5 + s_{56} z_{45} - s_{61} z_4 z_5,
\end{align*}
\]

(A.4)

which is the appropriately shifted version of the non-gothic polynomials

\[
\begin{align*}
h_1^5 &= s_{12} z_{23} - s_{23} z_{34} + s_{45} z_{34} - s_{51} z_4, \\
h_2^5 &= s_{12} z_{23} z_4 + s_{345} z_{32} z_4 + s_{45} z_{34} - s_{51} z_4 z_3.
\end{align*}
\]

(A.5)

Now, more generally, suppose \( a > 2 \) and consider \( z_1 \to \infty \),

\[
\begin{align*}
h_N(z_a) \bigg|_{z_{a-1}=z_a} &= s_{a-1,a} \prod_{b \neq a-1,a} (z_b - z_a), \\
h_N(z_b) \bigg|_{z_{a-1}=z_a} &= (z_a - z_b) h_{N-1}^{N-1}(z_b), \quad b \neq a - 2, a - 1, a, a + 1, \\
h_N(z_{a-2}) \bigg|_{z_{a-1}=z_a} &= (z_a - z_{a-2}) h_{N-1}^{N-1}(z_{a-2}) \\
&\quad + s_{a-1,a} (z_{a+1} - z_a)(z_{a-2} - z_a) \prod_{b \neq a-2,a-1,a,a+1} (z_b - z_{a-2}), \quad a \neq 3, \\
h_N(z_{a+1}) \bigg|_{z_{a-1}=z_a} &= (z_a - z_{a+1}) h_{N-1}^{N-1}(z_{a+1}) \\
&\quad + s_{a-1,a} (z_{a+1} - z_a)(z_{a-2} - z_a) \prod_{b \neq a-2,a-1,a,a+1} (z_b - z_{a+1}), \quad a \neq N,
\end{align*}
\]

(A.6)
and we also have
\[ h_1^N \bigg|_{z_{a-1}=z_a} = h_1^{N-1}. \]  
(A.7)

In the particular case considered in subsection 3.3, where we take \( z_1 \to \infty, z_2 = 1, z_3 = x, z_4 = y, z_N = 0, \)

\[
\begin{align*}
 h(y) \bigg|_{x=y} &= s_{34} \prod_{b \neq 1,3,4} (z_b - y), \\
 h(z_b) \bigg|_{x=y} &= (y - z_b)h_{(z_b)}^{N-1}, \quad b \geq 6, \\
 h(1) \bigg|_{x=y} &= (y - 1)h_{(1)}^{N-1} + s_{34}(z_5 - y)(1 - y) \prod_{b \geq 6} (z_b - 1), \\
 h(z_5) \bigg|_{x=y} &= (y - z_5)h_{(z_5)}^{N-1} + s_{34}(z_5 - y)(1 - y) \prod_{b \geq 6} (z_b - z_5). 
\end{align*}
\]
(A.8)

**Appendix B  An \( N = 8 \) Example**

As a further example, we consider the \( N=8 \) diagram \( \tilde{M} \) of Fig. 4a. After fixing Möbius invariance, the CHY integral for the corresponding amplitude, \( \tilde{A}^M_8 \), has three simple poles in the denominator, illustrating the growing complexity that is possible as \( N \) increases. At first glance, this would seem to make the evaluation of the integral using the global residue theorem more complicated. However, this complication is avoided by exchanging the scattering polynomials \( h_N^{(a)} \) for the linear combinations \( h_N^{(z_a+b)} \), \( 2 \leq a \leq N - 3 \), reducing the number of simple poles to just one, and thus putting the integrand into a form where the global residue theorem can be applied simply.
Writing $z_{ab} = z_a - z_b$,

\[
\tilde{A}_8^\tilde{M} = \oint \frac{dz_3 dz_4 dz_5 dz_6 dz_7}{h_1^8 h_2^8 h_3^8 h_4^8 h_5^8} z_{34567} \begin{array}{c}
\frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2} \frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2} \frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2}
\end{array}
\]

\[
= \oint \frac{dz_3 dz_4 dz_5 dz_6 dz_7}{h_1^8 h_2^8 h_3^8 h_4^8 h_5^8} z_{34} \begin{array}{c}
\frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2} \frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2} \frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2}
\end{array}
\]

\[
= \frac{1}{s_{34}} \oint \frac{dz_3 dz_4 dz_5 dz_6 dz_7}{h_1^8 h_2^8 h_3^8 h_4^8 h_5^8} z_{56} \begin{array}{c}
\frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2} \frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2} \frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2}
\end{array}
\]

\[
= -\frac{1}{s_{34}} \oint \frac{dz_3 dz_4 dz_5 dz_6 dz_7}{h_1^8 h_2^8 h_3^8 h_4^8 h_5^8} z_{56} \begin{array}{c}
\frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2} \frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2} \frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2}
\end{array}
\]

\[
= -\frac{1}{s_{34}} \oint \frac{dz_3 dz_4 dz_5 dz_6 dz_7}{h_1^8 h_2^8 h_3^8 h_4^8 h_5^8} z_{56} \begin{array}{c}
\frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2} \frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2} \frac{z_3^2 z_4^2 z_5^2 z_6^2 z_7^2}{z_34^2 z_5^2 z_6^2 z_7^2}
\end{array}
\]

where $A_{77}^{\tilde{M}}$ is the amplitude associated with Fig. 4b, since, when $z_{34} = 0$,

\[
h_1^8 = h_1^7, \quad h_2^8 = s_{345} z_{23} z_{65} z_5, \quad h_3^8 = z_{36} h_0^8, \quad h_4^8 = z_{27} h_0^7, \quad h_5^8 = z_{46} h_0^7.
