ABSTRACT

The study was carried out in the University of Nigeria, Nsukka, Nigeria from 2010 to 2011 to assess the effect of poultry manure application on growth and performance of potted moringa (Moringa oleifera Lam) plants raised for urban dwellers’ use. Application of 5 and 10 t ha⁻¹ of poultry manure to the soil medium ensured consistent increase in the plant height, stem girth, internode length, number of leaves and branches. The control treatment (0 t ha⁻¹) had the least values of all the morphological characteristics. The 10 t ha⁻¹ poultry manure treatment gave significant increase (p<0.05) in the plant growth vigour in the first two months of growth with a decrease in the third month. There were significant accession by poultry manure interaction effects (p<0.05) in the days to initial, 50% flowering and fresh leaf biomass production/plant and none in the days to 100% flowering, days to pod formation, number of pods/plant, number of seeds/pod, pod length and pod circumference. The 10 t ha⁻¹ poultry manure gave the highest values of all the yield traits in 2011 followed by 5 and 0 t ha⁻¹, respectively. There were significant accession by manure interaction effects (p<0.05) on all the yield traits except days to first and 50% flowering. There were lesser days to first, 50, 100% flowering and pod formation and higher values of all the other yield traits in 2011 than in 2010.

Key words: Nigeria, potted moringa plants, poultry manure, urban dwellers

INTRODUCTION

Moringa oleifera is a small deciduous, fast growing and drought resistant plant. It is also a perennial tree which can reach a maximum height of 7-12 m and a diameter of 20-40 cm at chest height. The stem is normally straight and branches at a height of 1.5 to 3 m (Becker et al., 2001). It grows best in loamy or sandy loam soil and can tolerate poor but not water-logged soils (Odee, 1998). Moringa oleifera is a highly nutritious and medicinal plant with great agricultural, industrial and domestic uses (Becker et al., 2001; Fahey, 2005; Fuglie, 2005).

Cultivation of moringa plants in the urban cities has not been adequately exploited in Nigeria because of land limitations. This problem can sufficiently be resolved by raising moringa plants in pots like plastic buckets, earthenware pots, baskets etc. The nutrient status of the potting medium (soil) in the container should be relatively high to support the life of the plant for a long period (Wilson et al., 2001) and can be augmented periodically with split doses of poultry manure and NPK fertilizer (Beaulah, 2001; Wilson et al., 2001). Beaulah (2001) integrated nutrient management in moringa production comprising organic manures, bio-fertilizers and varying levels of N, P and K.
The results showed a positive response of moringa plants to the application of manure and fertilizers. Containers with greater heights and volumes gave higher root volumes and biomass yield compared with those of lower dimensions (Ndubuaku and Oyekanmi, 2000). The use of a mixture of topsoil, poultry manure and sawdust for raising potted cocoa plants was reported by Ndubuaku and Oyekanmi (2000). Baiyeri (2005) evaluated three soilless media for weaning banana plantlets. The study showed that most of the genotypes evaluated grew into high quality seedlings when grown in rice hull composted with poultry manure. The leaves of the potted moringa plants can be harvested periodically to use as the plant re-flushes fast. Pinching the terminal bud on the central leader stem is necessary when it attains a height of 75 cm. This will promote the growth of many lateral branches and reduce the height of the tree (Vijayakumar, 2000). Vijayakumar (2000) found that early pinching of growing tips of moringa plants carried out 60 days after sowing supported a higher yield. Potted moringa plants can be kept as outdoor plants and watered routinely especially during the dry season. Moringa trees can also be planted as hedge-row plants around houses, parks, schools, hospital etc. (Ndubuaku and Ndubuaku, 2011). Moringa plants respond well to irrigation and the yield can be doubled by drip irrigation as compared to rain fed crops (Rajakrishnamoorthy et al., 1994).

The study was carried out to assess the effect of poultry manure application on growth and performance of potted moringa (*Moringa oleifera* Lam) plants raised for urban dwellers’ use.

**MATERIALS AND METHODS**

Fifty four black plastic buckets of 30 L capacity perforated at the base were used to raise the moringa plants in an un-shaded nursery in the Department of Crop Science, Faculty of Agriculture, University of Nigeria, Nsukka, Nigeria. Each bucket contained 25 kg of soil. Cured poultry manure was incorporated into the soil in the bucket at the rates of 0, 5 and 10 t ha⁻¹, respectively before sowing the seeds. Three seeds were planted in each bucket. The moringa seeds used for the experiment were collected from three locations in Nigeria namely; Nsukka (in the southeast), Ibadan (in the west) and Jos (in the north). The experimental design was a 3×3 factorial in completely randomized design with three replications. Morphological growth and yield attributes of the plants were monitored for two years; 2010 and 2011. Sowing of the seeds was done in April, 2010 and the records of the morphological growth and yields were taken till December, 2010 for the first phase of growth. The subsequent yield records were taken till September, 2011.

The morphological characteristics measured included the stem height (cm), stem girth (cm), number of leaves, number of branches, internode length and plant growth vigour. The parameters were recorded monthly. The root volume was determined at the ninth month of the study to avoid frequent destructive sampling.

Plant height was measured from the base of the plant to the tip of the terminal leaf bud with a meter rule. Stem diameter was measured five centimeters above ground level using micrometer screw gauge and converted to girth using the following formula:

\[ G = D\pi \]

where, \( G \) is the stem girth, \( D \) is the stem diameter and \( \pi \) is a constant (\( \pi = 22/7 \)).

The number of leaves and branches were determined by counting. The internode length was measured with a meter rule between two adjacent nodes. The root volume was determined by immersing the root system into a calibrated cylinder with a known volume of water and recording
the displacement (d) according to Ndubuaku and Oyekanmi (2000) and Ndubuaku (2003). The formula is as follows:

\[
\text{Root Volume (RV)} = \text{Final Water Volume (FWV) - Initial Water Volume (IWV)} = \text{Displacement (d)}
\]

Thus, \(RV = FWV - IWV = d\)

The plant growth vigour was determined by using the assessment indices for the growth of *Moringa oleifera* plant as shown in Table 1.

The yield attributes measured included days to flowering which was recorded as the number of days from sowing to first flower production; days to 50 and 100% flowering recorded as the number of days from sowing to when 50 and 100% of the plants flowered, days to pod formation and setting, number of pods/plant, number of seeds per pod, pod length (cm) and pod circumference (cm). After the first year’s (2010’s) yield, the apical shoot was pruned from a height of 50 cm above the ground and all the leaves harvested (apart from the abscised leaves) to determine the fresh leaf biomass and prepare for 2011 yield.

**RESULTS**

Application of five and 10 t ha\(^{-1}\) of poultry manure to the soil medium ensured consistent increase in the plant height, stem girth, internode length, number of leaves and branches. The control treatment (0 t ha\(^{-1}\)) had the least values of all the morphological characteristics (Fig. 1a-f). The poultry manure levels showed significant differences (\(p<0.05\)) in the plant height and stem girth all through the growth period (Fig. 1a-b) and in internode length at the second month (Fig. 1d), number of leaves and branches at the third month (Fig. 1c and e). The 10 t ha\(^{-1}\) poultry manure treatment gave significant increase (\(p<0.05\)) in the plant growth vigour in the first two months of growth with a decrease in the third month. The plants treated with 5 t ha\(^{-1}\) poultry manure grew vigorously within the first three months after planting and decreased in their growth vigour on the fourth and sixth months. The control plants decreased consistently in their growth vigour from the fourth month after planting. However, there were significant differences (\(p<0.05\)) in the effects of the poultry manure levels on plant growth vigour which reflected all through the growth period in 2010 (Fig. 1f). The 10 t ha\(^{-1}\) poultry manure gave the highest values of the plant height, stem girth, plant growth vigour, number of leaves and branches at the ninth month of the plants growth in 2010. The internode length values obtained in the five and 10 t ha\(^{-1}\) manure treatments were statistically similar at the ninth month.

There were no significant accession differences (\(p>0.05\)) in the morphological traits at the ninth month of the plants growth in 2010 (Table 2). Table 3 shows the interaction effects of accessions and poultry manure levels on yield traits in 2010. There were significant differences (\(p<0.05\)) in the

DF<sub>1</sub>: Days of first flowering, DF<sub>50</sub>: Days of 50% flowering, DF<sub>100</sub>: Days of 100% flowering, DPF: Days to pod formation, PL: Pod length, PC: Pod Circumference, NS: Number of seed/pod, NP: No. of pods/plant, FLB/pot: Fresh leaf biomass/plant, ns: Not significant

Nsukka accession gave the highest leaf biomass production followed by Jos and Ibadan accessions, respectively. The 10 t ha<sup>-1</sup> gave the least number of days to pod formation and the highest values of the number of pods/plant, number of seeds/pod, fresh leaf biomass, pod length and circumference. Table 4 shows the interaction effects of accessions by poultry manure on the yield traits in 2011. The 10 t ha<sup>-1</sup> poultry manure gave the highest number of days to first, 50 and 100% flowering as well as all the yield traits in 2011 followed by 5 and 0 t ha<sup>-1</sup>, respectively. There were significant accession by manure interaction effects (p<0.05) on all the yield traits except days to first and 50% flowering. There were lesser days to first, 50, 100% flowering and pod formation but higher values of all the other yield traits in 2011 than in 2010 as shown in Table 3 and 4.

No records of the morphological growth characteristics were taken in 2011, because of the pruning of the shoot in December, 2010, to avoid inconsistencies in the results.

**DISCUSSION**

The higher values of the morphological and yield traits obtained with poultry manure application was a good indication that moringa plants could respond positively to manure application. Beaulah (2001) integrated nutrient management encompassing organic manures, bio-fertilizers and varying levels of N, P and K in moringa production and his results showed a
positive response of moringa to the application of manure and fertilizers. Topsoil and poultry manure mixtures can, therefore, constitute a suitable medium for potting moringa plants for urban dwellers’ use. The use of a mixture of topsoil, poultry manure and sawdust in potted cocoa plants was reported by Ndubuaku and Oyekanmi (2000). There was faster flowering and pod setting in 2011 than 2010 probably due to age of the plants. There was delayed pod setting in the plants raised in the poultry manure media in 2011. This could be due to competitive effects of vegetative growth which could have delayed the onset of reproductive growth such as flowering and pod formation in the poultry manure media. The 10 t ha\(^{-1}\) poultry manure application gave the greatest values of both morphological and pod yield. However, the optimum level should be ascertained in subsequent trials.

Greater values of all the pod yield traits were obtained in the poultry manure media in 2011 than 2010 probably due to residual effects of the nutrients released from the manure. Manures are slow-release fertilizers and usually have residual effects on the crops in subsequent cropping seasons as earlier found by Ndubuaku et al. (2014). There was greater fresh leaf biomass in 2011 than 2010 as a result of pruning of the shoot done in December, 2010 which resulted into profuse branching and flushing (leaf production) in 2011. The differences exhibited by the different accessions in the morphological and yield traits could be phenotypic and not genotypic. This can be confirmed in further studies.

The urban dwellers can, therefore, be afforded the privilege of growing moringa in plastic buckets or any other suitable container with a mixture of topsoil and poultry manure. The nutrient status of the planting medium can be upgraded periodically with split doses of poultry manure and nitrogen: phosphorus: potassium (NPK) fertilizer. The leaves can be harvested periodically for use as pruning of leaves in this study increased leaf biomass production and pod yield.

ACKNOWLEDGMENT
We (the authors) acknowledge and appreciate the efforts of the Head of Department of Crop Science, Faculty of Agriculture, University of Nigeria, Nsukka for giving us the privilege to carry out the experiment in the departmental nursery.
