Abstract

We explore BPS soliton configurations in \( N = 2 \) supersymmetric Yang-Mills theory with matter fields arising from parallel \( D3 \) branes on \( D7 \) branes. Especially we focus on two parameter family of 1/8 BPS equations, dyonic objects, and 1/8 BPS objects and raise a possibility of absence of BPS vortices when the number of \( D3 \) branes is larger than that of \( D7 \) branes.
1 Introduction and Conclusion

Recently there has been a considerable interest in BPS solitons in Higgs phase of supersymmetric Yang-Mills theories with eight supercharges\cite{1, 2, 3, 4, 5, 6}. Almost all known BPS objects, like magnetic flux vortices\cite{7, 8, 9}, magnetic monopoles\cite{10}, domain walls\cite{11, 12}, and instantons\cite{4, 13, 14, 15}, have appeared here, sometimes with a bit of twist. These theories can allow many degenerate vacua which can be interpolated by domain walls. With broken $U(1)$ gauge theories, one can have magnetic flux vortex. One of the most interesting features has been that there can be magnetic monopoles which appear as beads on vortex strings\cite{16}.

These BPS objects can be interpreted in a simple manner from D-brane point of view\cite{17}. Especially a simple but rich picture appears with $N$ parallel D3 branes and $N_f$ D7 branes. In this setting, one can have $N = 2$ supersymmetric $U(N)$ gauge theory with $N_f$ matter hypermultiplets in the fundamental representation and a single adjoint hypermultiplet. One can add Fayet-Iliopoulos(FI)-terms and mass term for the matter hypermultiplet without breaking the supersymmetry. There are considerable work done along this line to represent the configurations in brane picture\cite{18}.

In this work, we focus on BPS equations, dyonic $1/4$ BPS, and $1/8$ BPS solutions. In addition, we explore BPS vortex equations when $N = 2, N_f = 1$ and found the cases where there are no vortex solutions of unit or double vorticity.

By studying the known bosonic BPS equations, we found that there are two parameter family of $1/8$ BPS equations in 3+1 dimension modulo spatial rotation and $SU(2)_R \times U(1)_R$. The FI term breaks $SU(2)_R$ to $U(1)$ and the mass terms for matter hypermultiplet breaks $U(1)_R$ completely. One would expect more general BPS configurations in this setting.

Dyonic objects mean objects carrying 'electric' charge. Of course there will be no isolated electric charge in the Higgs phase due to screening. Electrically charged solitons could be interpreted as composites of soliton with...
fundamental strings whose ends carry electric charge. In Higgs phase the electric charge is neutralized by electric charge carried by the Higgs field. As the Higgs fields carry global flavor charge, the conserved flavor charge instead of the total electric flux would appear in the BPS energy formula. Besides dyonic monopoles, we show that dyonic domain walls as well as dyonic composites of domain wall-monopole-vortex are also possible. When parallel D7 branes are not lying on a single line in their transverse space, dyonic BPS configurations which make web-like structures are also possible. These dyonic solutions could be interpreted as the excitations in phase moduli of BPS objects and they belong to 1/4 BPS states.

We also look for BPS solutions preserving 1/8 of eight supersymmetries. By exploring a small perturbation of a homogeneous 1/4 BPS configuration in 3+1 dimensional theories, we argue that there may be no 1/8 BPS configurations satisfying the BPS equations. However we find easily 1/8 BPS configurations in a theory with product gauge group \( U(1) \times U(1) \) with bifundamental and fundamental matter field. In this analysis, the recently discovered \(^5\) bound states of monopoles and domain walls play some role.

The key aspect here is that the FI parameters breaks the \( SU(2)_R \) symmetry of eight supersymmetric 5+1 dimensional theory. For a single \( U(1) \) gauge group, one can use the broken R-symmetry to choose a single direction in \( SU(2)_R \) space. However with product gauge groups, the FI-parameters cannot be rotated to a single direction in general. This is what allows the presence of 1/8 BPS configurations possible.

As there are multi BPS vortex string configuration in \( U(1) \) theory with \( N_f = 1 \), we may expect there are BPS vortex string configuration in \( U(2) \) theory with \( N_f = 1 \). While there exist degenerate supersymmetric vacua, we will show that classically there exists no BPS vortex configuration with unit and double magnetic flux. We argue that this may imply that there exists no BPS vortex solitons of finite magnetic flux in the theory.

One interesting direction to explore further is the interaction between
domain walls and monopoles. (See also a recent work by Sakai and Tong.)

In string picture, parallel D1 and D3 branes are attracted to each other. This
is not apparent from the energy argument of a BPS monopole-vortex-domain
composition. The moduli space of domain wall-monopole separation should
be analyzed carefully to resolve the question.

Another direction is to study the moduli space dynamics of magnetic
monopoles and domain walls when some of nonabelian gauge symmetry is
restored. It would be interesting to see whether there exists a similar restora-
tion of symmetry in the moduli space dynamics..

Finally, all BPS solutions we study here have extended structures with
infinite energy. There may be finite action BPS solitons in the theory. Espe-
cially it may be possible to have finite energy (dyonic) instantons in \( R^3 \times S^1 \)
(noncommutative) space, which do not have diverging gauge flux\[15\].

The plan of this paper is as follows. In Sec.2, we describe 5+1 dimensional
supersymmetric Yang-Mills theories and find supersymmetric Lagrangian
and its vacuum structure. In Sec.3, we find two parametered BPS equa-
tions, especially 1/8 BPS equations. In Sec.4, we study dyonic solutions. In
Sec.5, we study 1/8 BPS configurations and find BPS configurations with
product gauge group. In Sec.6, we show that there exists no BPS vortex
solitons of unit and double magnetic flux when \( N = 2 \) and \( N_f = 1 \).

Note added : In the early stage of the draft of our paper, we came to
know that the authors of Ref.[19] have worked on the classification of 1/8
BPS equations of the similar model we considered.

2 Six Dimensional Case

The vector multiplet of super Yang-Mills theory of \( U(N) \) gauge group with
eight supersymmetries in six dimensions is made of \( A_M, \lambda_i (i = 1, 2), D^a, \)
which are hermitian \( N \times N \) matrix valued fields. The gaugino field \( \lambda_i, i = 1, 2 \) is made of two eight component spinors satisfying both chirality and
symplectic Majorana conditions
\[ \Gamma^6 \lambda_i = \lambda_i \quad (i = 1, 2), \quad \lambda_i = (i\sigma^2)_{ij} B(\lambda_j^T) \tag{2.1} \]
where \( B \) is a matrix such that \( B \Gamma^M B^{-1} = (\Gamma^M)^* \). Due to this constraint, there are only four physical degrees of freedom in gaugino spinor. Our choice of six dimensional Gamma matrices are
\[ \Gamma^0 = 1_2 \otimes \sigma^3 \otimes \sigma^1, \quad \Gamma^a = \sigma_a \otimes \sigma^1 \otimes \sigma^1 \quad (a = 1, 2, 3) \]
\[ \Gamma^4 = 1_2 \otimes \sigma^2 \otimes \sigma^1, \quad \Gamma^5 = 1_2 \otimes 1_2 \otimes \sigma^2 \tag{2.2} \]
In addition, \( \Gamma^6 = \Gamma^0 \Gamma^1 \cdots \Gamma^5 = 1_2 \otimes 1_2 \otimes \sigma^3 \). With the above choice,
\[ B = -i\sigma^2 \otimes 1_2 \otimes \sigma^3. \tag{2.3} \]

The Lagrangian for the gauge multiplet is
\[ \mathcal{L}_1 = \text{tr} \left( -\frac{1}{4} F_{MN} F^{MN} - \frac{i}{2} \bar{\lambda}_i \Gamma^M D_M \lambda_i + \frac{1}{2} (D^a)^2 \right) \tag{2.4} \]
The supersymmetric transformation becomes
\[ \delta A_M = i \bar{\lambda}_i \Gamma_M \epsilon_i \tag{2.5} \]
\[ \delta \lambda_i = \frac{1}{2} F_{MN} \Gamma^{MN} \epsilon_i + i D^a \sigma^a_{ij} \epsilon_j \tag{2.6} \]
\[ \delta D^a = \bar{\epsilon}_i \sigma^a_{ij} \Gamma^I D_I \lambda_j \tag{2.7} \]
where the supersymmetric parameter \( \epsilon_i \) is also a chiral spinor and satisfies the symplectic Majorana condition. The Lagrangian and supersymmetric transformation are compatible with the symplectic Majorana condition. The above Lagrangian is invariant under \( SU(2)_R \) transformation, under which \( \lambda_i \) and \( D^a \) belong to the fundamental and adjoint representations, respectively.

The Lagrangian for an adjoint hypermultiplet \( y_i \quad (i = 1, 2), \chi \) where the matter spinor is anti-chiral \( \Gamma^6 \chi = -\chi \), is
\[ \mathcal{L}_2 = \text{tr} \left( -\frac{1}{2} D_M \bar{y}_i D^M y_i + \frac{1}{2} D^a \sigma^a_{ij} \bar{[y}_j, y_i] - i \bar{\chi} \Gamma^M D_M \chi + \bar{\lambda}_i [\bar{y}_i, \chi] - \bar{\chi} [y_i, \lambda_i] \right) \tag{2.8} \]
where \( D_M y_i = \partial_M y_i - i[A_M, y_i] \). Here \( y_i (i = 1, 2) \) is a doublet under \( SU(2)_R \) and \( \chi \) is a singlet. The supersymmetric transformation is

\[
\delta \bar{y}_i = 2i \bar{\chi}_i \epsilon_i, \quad \delta \chi = D_M y_i \Gamma^M \epsilon_i \tag{2.9}
\]

The matter hypermultiplets \( q_{fi}, \psi_f \) with flavor index \( f = 1, \ldots, N_f \) belong to the fundamental representation \( \bar{N} \) of the gauge group \( U(N) \). As in the adjoint hypermultiplet, the matter spinor field is anti-chiral. The Lagrangian for the matter multiplet is

\[
L_3 = \text{tr} \left( -\frac{1}{2} D_M \bar{q}_{fi} D^M q_{fi} + \frac{1}{2} D^a \sigma^a_{ij} \bar{q}_{fj} q_{fi} - i \bar{\psi}_f \Gamma^M D_M \psi_f + \bar{\lambda}_i \bar{q}_{fi} \psi_f - i \bar{\psi}_f q_{fi} \lambda_i \right) \tag{2.10}
\]

where \( D_M q_{fi} = \partial_M q_{fi} + iq_{fi} A_M \). The supersymmetric transformation is

\[
\delta \bar{q}_{fi} = 2i \bar{\psi}_f i \epsilon_i, \quad \delta \psi_f = D_M q_{fi} \Gamma^M \epsilon_i \tag{2.11}
\]

The above Lagrangians are invariant under the \( SU(2)_R \) symmetry. For a theory with abelian gauge group, one can add the Fayet- Iliopoulos term

\[
L_{FI} = \frac{1}{2} \text{tr}(\zeta^a D^a). \tag{2.12}
\]

If the gauge group is a product group, there would be FI-terms for each independent \( U(1) \) theory. The FI parameters \( \zeta^a \) breaks the \( SU(2)_R \) symmetry explicitly and so one can use \( SU(2)_R \) symmetry to rotate them to be

\[
\zeta^1 = 0, \quad \zeta^2 = 0, \quad \zeta^3 = v^2 \tag{2.13}
\]

with \( v \geq 0 \). We will use both \( \zeta^a \) and parameter \( v \). The \( D^a \) field is not dynamical and its field equation leads to

\[
D^a = \frac{e^2}{2} \left\{ \zeta^a - \sigma^a_{ij} \left( [\bar{y}_j, y_i] + \bar{q}_{fj} q_{fi} \right) \right\} \tag{2.14}
\]

The dimensional reduction to 3+1 dimension induces additional \( U(1)_R \) symmetry which is a rotation under two reduced space. The dimensional
reduction with Scherk-Schwartz mechanism induces two mass parameters $m_f, m'_f$ for each flavor matter multiplet along the reduced space. If $x^4, x^5$ is reduced, then

$$D_4 q_{fi} = i q_{fi} (A_4 - m_f), \quad D_5 q_{fi} = i q_{fi} (A_5 - m'_f).$$

(2.15)

This theory with $U(N)$ gauge group has a simple D-brane interpretation. It is a Yang-Mills theory on $N$ parallel D3 branes near $N_f$ D7 branes whose transverse location at $x^4, x^5$ is given by the mass parameter. The location of D3 branes along $x^4, x^5$ direction is given by the vacuum expectation value of adjoint scalars $A_4, A_5$. The location of D3 branes along transverse 4 directions in D7 branes would be decided by the expectation value of $y_i$. The dimensional reduction to 4 + 1 dimension is a bit simpler with only one mass parameter and no additional R-symmetry. The D-brane interpretation could be D4-D8 system.

One of the vacuum condition $D^a = 0$ is the ADHM condition of $N$ instantons on $U(N_f)$ gauge theory of noncommutative four space. The scalar fields are denoting the separation and size of instantons. As D3 branes act as instantons on D7 branes, one can see that the vacuum moduli space modulo gauge transformation is the moduli space of instantons when the mass parameters are turned off. With the mass parameters turned on, every D3 brane should lie on some D7 brane at the ground state. Thus, every eigenvalue pair of expectation value of $(A_4, A_5)$, which is diagonal at the vacuum, should coincide with $(m_f, m'_f)$ for some $f$.

One of the simplest vacua appears when $N = N_f$ and all the eigenvalue pair of $A_4, A_5$ are distinct, such that there is only one D3 brane for each D7 brane. It is the so-called color-flavor locking phase, where the matter field will have a Higgs condensation $\langle q_{f1} \rangle_{\text{vacuum}} = v$ and the gauge symmetry plus the flavor symmetry is spontaneously broken down to unbroken $U(1)^N$ global symmetry.

When $N = 2, N_f = 1$, the vacuum moduli space would be that of two $U(1)$ instantons on noncommutative four space[20], which is the so-called Eguchi-
Hanson space. In this case $y_i$ does have intrinsic nonabelian components and the gauge group $U(2)$ is spontaneously broken to global $U(1)$ symmetry.

3 BPS Equations

Classically a BPS field configuration is a bosonic field configuration which leaves some of the supersymmetry invariant. We consider now the supersymmetric transformation to obtain the BPS equations. Inspired by the bosonic BPS equations, we rewrite the supersymmetric transformation of the gaugino field as

$$
\delta \lambda_i = \Gamma^{12} \left( (F_{12} - F_{34} \Gamma^{1234}) \epsilon_i - i D^3 \Gamma^{12} \sigma^3_{ij} \epsilon_j \right) + \Gamma^{23} \left( (F_{23} - F_{41} \Gamma^{1234}) \epsilon_i - i D^1 \Gamma^{23} \sigma^1_{ij} \epsilon_j \right) + \Gamma^{31} \left( (F_{31} - F_{24} \Gamma^{1234}) \epsilon_i - i D^2 \Gamma^{31} \sigma^2_{ij} \epsilon_j \right) + \Gamma^{1234} \left( (F_{1234} - F_{50} \Gamma^{05}) \epsilon_i + F_{05} \Gamma^{05} \epsilon_i \right) 
$$

(3.16)

As $\Gamma^4 \epsilon_i = -\Gamma^{123} \Gamma^{05} \epsilon_i$, the adjoint spinor transformation is written as

$$
\delta \chi = -\Gamma^{123} \left( D_1 y_i \Gamma^{23} + D_2 y_i \Gamma^{31} + D_3 y_i \Gamma^{12} + D_4 y_i \Gamma^{05} \right) \epsilon_i + \Gamma^0 (D_0 y_i - D_5 y_i \Gamma^{05}) \epsilon_i 
$$

(3.17)

The spinor in fundamental hypermultiplet transforms as

$$
\delta \psi_f = -\Gamma^{123} \left( D_1 q_{f1} \Gamma^{23} + D_2 q_{f1} \Gamma^{31} + D_3 q_{f1} \Gamma^{12} + D_4 q_{f1} \Gamma^{05} \right) \epsilon_i + \Gamma^0 (D_0 q_{f1} - D_5 q_{f1} \Gamma^{05}) \epsilon_i 
$$

(3.18)

We want find some supersymmetric parameter $\epsilon_i$ such that $\delta \lambda_i, \delta \chi, \delta \psi_f$ remain zero. On eight independent parameters of spinor $\epsilon_i$, we impose three independent conditions (In the case of $N = 2$ NLSM, see [21].),

$$
\Gamma^{05} \epsilon_i = \eta \epsilon_i, \quad \Gamma^{12} \sigma^3_{ij} \epsilon_j = i \alpha \epsilon_i, \quad \Gamma^{23} \sigma^1_{ij} \epsilon_j = i \beta \epsilon_i 
$$

(3.19)

with $\alpha, \beta, \eta$ take $\pm 1$ independently. Since $\Gamma^0 \Gamma^1 \ldots \Gamma^5 = 1$ for chiral $\epsilon_i$, these conditions imply that

$$
\Gamma^{31} \sigma^2_{ij} \epsilon_i = -i \alpha \beta \epsilon_i, \quad \Gamma^{1234} \epsilon_i = \eta \epsilon_i 
$$

(3.20)
These are conditions on eight independent Majorana parameters in the spinor $\epsilon_i$, as they are compatible with the symplectic Majorana condition. If we impose any one of the conditions, the number of independent SUSY parameters would be reduced by one half to four of the original value. If we impose any two of them, the number of independent SUSY parameters are reduced to two or 1/4 of the original one. If we impose all three of them, the number of independent parameters is reduced to one, 1/8 of the original value.

One can obtain different conditions by six dimensional Lorentz transformations and $SU(2)_R$ transformations. In reduction to 3 + 1 dimensions, only nontrivial ones modulo remaining symmetries is the rotation between the remaining coordinates and the reduced coordinates. In the reduction to 3 + 1 dimensions of coordinate $x^0, x^1, x^2, x^3$, the above condition can be generalized to new spinor conditions with two parameters,

$$\Gamma^0 (\Gamma^5 \cos \theta + \Gamma^3 \sin \theta) \epsilon_i = \eta \epsilon_i,$$
$$\Gamma^1 (\Gamma^2 \cos \varphi + \Gamma^4 \sin \varphi) \sigma_{ij}^3 \epsilon_{ij} = i \alpha \epsilon_i,$$
$$(\Gamma^2 \cos \varphi + \Gamma^4 \sin \varphi) (\Gamma^3 \cos \theta - \Gamma^5 \sin \theta) \sigma_{ij}^1 \epsilon_{ij} = i \beta \epsilon_i$$  \hspace{1cm} (3.21)

This implies that

$$(\Gamma^3 \cos \theta - \Gamma^5 \sin \theta) \Gamma^1 \sigma_{ij}^2 \epsilon_{ij} = -i \alpha \beta \epsilon_i,$$
$$\Gamma^{124} (-\Gamma^3 \cos \theta + \Gamma^5 \sin \theta) \epsilon_i = \eta \epsilon_i,$$  \hspace{1cm} (3.22)

Note also $D_4 q_{fi} = i q_{fi} (A_4 - m_f)$ and $D_5 q_{fi} = i q_{fi} (A_5 - m'_f)$. In reduction to 4 + 1, we can put $\varphi = 0$ as it is a part of four dimensional spatial rotation.

We use the generalized spinor condition (3.21) to find the BPS equations satisfied by the bosonic configurations for the minimum amount 1/8 of the original supersymmetries. For any vector with spatial indices, we introduce barred indices so that

$$V_\bar{1} = V_1, \ V_\bar{2} = V_2 \cos \varphi + V_4 \sin \varphi, \ V_\bar{3} = V_3 \cos \theta - V_5 \sin \theta,$$
$$V_\bar{4} = V_4 \cos \varphi - V_2 \sin \varphi, \ V_\bar{5} = V_5 \cos \theta + V_3 \sin \theta$$  \hspace{1cm} (3.23)
From $\delta \lambda_i = 0$, we get the gauge field part of BPS equations,

\[
\begin{align*}
F_{\mu 5} &= 0, \\ F_{\mu 0} - \eta F_{\mu 5} &= 0 \quad (\mu = 1, \ldots, 4), \\ F_{12} - \eta F_{34} + \alpha D^3 &= 0, \\ F_{23} - \eta F_{14} + \beta D^1 &= 0, \\ F_{31} - \eta F_{24} - \alpha \beta D^2 &= 0,
\end{align*}
\tag{3.24}
\]

From $\delta \chi = 0$ and $\delta \psi_f = 0$, we also obtain

\[
\begin{align*}
\beta D_1 y_j \sigma^1_{ji} - \alpha \beta D_2 y_j \sigma^2_{ji} + \alpha D_3 y_j \sigma^3_{ji} - i \eta D_4 y_i &= 0, \\ D_0 y_i - \eta D_5 y_i &= 0, \\ D_0 \bar{q}_{fi} - \eta D_5 q_{fi} &= 0, \\ \beta D_1 q_{fj} \sigma^1_{ji} - \alpha \beta D_2 q_{fj} \sigma^2_{ji} + \alpha D_3 q_{fj} \sigma^3_{ji} - i \eta D_4 q_{fi} &= 0
\end{align*}
\tag{3.25}
\]

These are the BPS equations for 1/8 BPS configurations. The BPS equations preserving more supersymmetry can be obtained by imposing additional conditions to the above BPS equations. For example, 1/4 BPS configurations satisfy two sets of 1/8 BPS equations with, say, both $\alpha = 1$ and $\alpha = -1$. There is also a Gauss law constraint for the BPS configurations,

\[
-\frac{1}{e^2} \sum_{\mu=0}^{5} D_\mu F_{\mu 0} - i \left( [\bar{y}_i, D_0 y_i] - [D_0 \bar{y}_i, y_i] \right) - \frac{i}{2} (\bar{q}_{fi}, D_0 q_{fi} - D_0 \bar{q}_{fi}, q_{fi}) = 0. \tag{3.26}
\]

Using the BPS equation, the central charge\[^{[22]}\] for the BPS energy bound can be found to be

\[
Z = \frac{1}{2} \int d^3 x \, \text{tr} \left( \frac{\eta}{2 e^2} F_{\mu \nu} \tilde{F}_{\mu \nu} - \alpha \zeta^3 (F_{12} - \eta F_{34}) - \beta \zeta^1 (F_{23} - \eta F_{14}) \right. \\
\left. + \alpha \beta \zeta^2 (F_{31} - \eta F_{24}) \right) + \eta m_f Q_f \cos \theta + \eta T_{03} \sin \theta + Z'
\tag{3.27}
\]

where $\mu, \nu = 1, 2, 3, 4$ and $\tilde{F}_{\mu \nu} = \frac{1}{2} \epsilon_{\mu \nu \rho \sigma} F_{\rho \sigma}$. After dimensional reduction to (3+1) dimensions, $D_4 y_i = -i [A_4, y_i]$ and $D_4 q_{fi} = i q_{fi} (A_4 - m_f)$, and so $F_{14} = D_1 A_4$ and $F_{15} = -i [A_4, A_5]$. The charge $Q_f$ is the one carried by the $f$'th-flavor matter field,

\[
Q_f = \frac{i}{2} \int d^3 x \, \text{tr} (\bar{q}_{fi}, D_0 q_{fi} - D_0 \bar{q}_{fi}, q_{fi}) \tag{3.28}
\]
and $T_{03}$ is the linear momentum along $x^3$ direction,

$$T_{03} = \frac{1}{2} \int d^3x \, \text{tr} \left( \frac{1}{e^2} \sum_{\mu=1,2,4,5} F_{\mu0} F_{\mu3} + (D_0 \bar{y}_i D_3 y_i + D_3 \bar{y}_i D_0 y_i) + (D_0 \bar{q}_{f_i} D_3 q_{f_i} + D_3 \bar{q}_{f_i} D_0 q_{f_i}) \right).$$  

(3.29)

The boundary term $Z'$ is given by

$$Z' = \int d^3x \left( \eta \partial_i \text{tr}(F_{i0} A_5) \cos \theta + \cdots \right),$$  

(3.30)

where $\cdots$ indicates the terms quadratic in matter fields and expected to have zero boundary contribution in both Coulomb and Higgs phases. The first part would have nontrivial contribution in the Coulomb phase where there would be nontrivial electric field.)

The above BPS equations and the energy bound are complicated functions of two parameters $\varphi$ and $\theta$. For example, a complication arises as

$$F_{34} = F_{34} \cos \theta \cos \varphi - F_{32} \cos \theta \sin \varphi - F_{54} \sin \theta \cos \varphi + F_{52} \sin \theta \sin \varphi.$$  

(3.31)

Using the un-bared coordinate indices, we note that the first term of the above expression can be expressed as

$$F_{\mu\nu} F_{\mu\nu} = F_{\mu\nu} F_{\mu\nu} \cos \theta + 4(F_{12} F_{45} + F_{24} F_{15} + F_{41} F_{25}) \sin \theta.$$  

(3.32)

There are also the boundary terms depending on quark fields, which is supposed to make vanishing contributions almost all cases.

Once we fix $\zeta^a = v^2 \delta_3^a$, which is possible for the theories of $U(N)$ gauge group but not for those with product gauge group like $U(1) \times U(1)$, the BPS energy does not depends on the choice of the parameter $\beta$. This means that 1/4 BPS configurations defined by $\alpha$ and $\eta$ parameters could have 1/8 BPS excitations without generating additional energy, which is strange. Indeed we see that this is impossible in some simple case studied in Sec.5.

We can choose two parameters $\theta, \varphi$ to be arbitrary. If we fix $\zeta^a$, we no longer have the freedom of $SU(2)_R$ transformation, and the parameters $\theta, \varphi$
become physically meaningful. One typical cases of BPS equations would be when $\theta = \varphi = 0$. In this case, the barred spacial indices become the un-barred ones and $\partial_4 = \partial_5 = 0$. The other extreme may be when $\theta = \varphi = \pi/2$. In this case the time dependent part becomes $F_{03} = 0, (D_0 - \eta D_3) \text{ any field} = 0,$ and

$$\eta F_{12} + i[A_4, A_5] + \beta D^1 = 0, \quad D_1 A_4 + \eta D_2 A_5 + \alpha D^3 = 0,$$

$$D_1 A_5 - \eta D_2 A_4 - \alpha \beta D^2 = 0,$$

$$\left( \beta D_1 y_j \sigma_{ji}^1 + i \eta D_2 y_i + i \alpha \beta [A_4, y_j] \sigma_{ji}^2 + i \alpha [A_5, y_j] \sigma_{ji}^3 \right) = 0,$$

$$\left( \beta D_1 q_f j \sigma_{ji}^1 + i \eta D_2 q_f j - i \alpha \beta q_f j (A_4 - m_f) \sigma_{ji}^2 - i \alpha q_f j (A_5 - m'_f) \sigma_{ji}^3 \right) = 0$$

(3.33)

We know quite a bit of the topological objects of the theories in $\theta = \varphi = 0$. The simplest object is a 1/2 BPS vortex soliton along $x^3$ direction in $U(1)$ theory with $N_f = 1$ [$9$]. It satisfies the BPS equation with $\beta = -1,$

$$2 F_{12} = v^2 - |q_1|^2, \quad (D_1 - i D_2)q_1 = 0,$$

(3.34)

where $y_i = 0, q_2 = 0$, dropping the flavor index. Especially a unit flux vortex has a vortex tension $T_v = \pi v^2$. This could be regarded as a D1 string on a single D3 brane in a single D7 brane. The next simplest object is a 1/2 BPS domain wall parallel to $(x^1, x^2)$ plane [$1$ [$2$ [$3$ [$23$]. With $N = 1$ and $N_f = 2$ with two different $m_f$ along $x^4$ direction, the 1/2 BPS equations with $\alpha \beta = 1$ becomes

$$2 \partial_3 A_4 = v^2 - \sum_{f=1}^{2} |q_{f1}|^2, \quad \partial_3 q_{f1} = -q_{f1} (A_4 - m_f),$$

(3.35)

where $y_i = 0, q_{f2} = 0, m_1 < m_2$, and $A_5 = 0$. The $A_4$ interpolates between $m_1$ and $m_2$. It describes the D3 brane on first D7 brane interpolating to the second D7 brane. The wall tension is $T_{12} = \pi v^2 (m_2 - m_1)$.

More complicated object is a 1/4 BPS configuration made of magnetic monopole beads in a vortex flux tube [$16$]. With $N = N_f = 2$ and in the color-flavor locking phase with $m_1 < m_2$ and $A_5 = m'_f = 0$, the D1 string
on the first D3-D7 branes can interpolate to the second D3-D7 branes. The D1 string connecting two D3 branes appears as a magnetic monopole. In the Higgs phase, the magnetic flux is confined to flux string and so the 1/4 BPS object is made of two vortices emerging opposite to the magnetic monopole, where two $U(1)$’s of $U(2)$ flux are carried to opposite direction. The composite has the energy of a simple sum of vortex tension and monopole mass.

Most complicated 1/4 BPS object is a composite made of vortex and domain walls, which also allows some magnetic monopoles\cite{5,24,25}. With $\beta = -1, \alpha = -1$, from the BPS energy one notices that with positive $\text{tr} F_{12}$ and $\text{tr} F_{34}$, which means postive vortex flux and domain wall charge where $A_4$ is increasing, there is negative instanton energy, or monopole energy. This is the so-called bound energy of vortex-domain wall\cite{5}. If a vortex terminates at the domain wall, the wall shape gets deformed in large distance away from the contact point. The detail has been also studied recently\cite{25}. Of course one can add additional monopole kink to this vortex-domain wall junction, which carries the positive monopole energy. In some cases, the magnetic monopole can pass the domain wall. When a vortex penetrating a domain wall is deformed so that the contact points at the both sides of the domain wall do not coincide to the same point, the monopole could not pass the domain wall due to the energy consideration, which means that there could be repulsive potential at the domain wall. It would be interesting to find whether our conjecture is true.

A typical solution of the BPS equations of $\theta = \varphi = \pi/2$ would be the 1/4 BPS domain wall junction\cite{6,26,27} with $N = 1, N_f = 3$. Suppose that the three complex masses $m_f + i m'_f$ lie on vertices of an equitriangle so that $m_f + i m'_f = m e^{2\pi i f/3}$ with $f = 1, 2, 3$. The BPS equation would be give by (3.34) with $\zeta^3 = v^2$ and the wall junction would lie on on $x^1, x^2$ plane with $x^3$ translation invariance. The ansatiz is that $y_i = 0, q_{f2} = 0, A_1 = A_2 =$
$A_3 = 0, \partial_3 = 0$ and the BPS equation becomes

$$
\partial_1 A_4 + \eta \partial_2 A_5 = -\frac{\alpha}{2} (v^2 - |q_{f_1}|^2), \quad \partial_1 A_5 - \eta \partial_2 A_4 = 0 \quad (3.36)
$$

$$
\partial_1 q_{f_1} - \alpha (A_4 - m_f) q_{f_1} = 0, \quad \eta \partial_2 q_{f_1} - \alpha (A_5 - m_f') q_{f_1} = 0 \quad (3.37)
$$

The web of wall solutions of this type in a bit more complicated setting has been also studied recently [6].

4 Lorentz Boosted, or Dyonic Solutions

For the BPS configurations, the time dependent part can be solved with

$$
A_0 = \eta (A_5 \cos \theta + A_3 \sin \theta), \quad \partial_0 q_{f_i} - \eta (\partial_3 \sin \theta - i m_f' \cos \theta) q_{f_i} = 0 \quad (4.38)
$$

while $(\partial_0 - \partial_3 \sin \theta) = 0$ for any field in the adjoint representation. One can see that it is a Lorentz boost along $x^3$ axis with velocity $v = \sin \theta$ when $|\theta| < \pi/2$. However, the $\theta = \pi/2$ case is still physically distinct as it cannot be obtained through finite boost. The Gauss law is also equivalently Lorentz boosted version. This matches with the energy being increased with $T_{03}v = \mathcal{O}(v^2)$ for small $v$ as $T_{03}$ itself is linear in $v$ for small $v$. For the domain wall junctions, $T_{03} = 0$ with $\theta = \pi/2$ due to the $x^3$ translation invariance of the configuration. Thus one cannot boost them along $x^3$, but may be able to put some massless wave along $x^3$ without breaking the supersymmetry further.

When $\theta = 0$, $A_0 = \eta A_5$ and the all adjoint fields are time-independent and $\partial_0 q_{f_i} + i \eta m_f' q_{f_i} = 0$. The $f$-th flavor charge becomes

$$
Q_f = \eta \int d^4x \, \text{tr} \left( (m_f' - A_5) \bar{q}_{f_i} q_{f_i} \right). \quad (4.39)
$$

As the total electric charge vanishes in the Higgs phase, we put the constraint $\sum_f Q_f = 0$. Here we consider the fundamental string connecting D3 branes with net $U(1) = \text{tr}(U(N))$ charge vanishes in the Higgs phase. The energy
carried by the flavor charge becomes

\[ E_Q = \eta \sum_f m'_f Q_f = \sum_f \int d^3 x \ m'_f \text{tr} \left( (m'_f - A_5)\bar{q}_fiq_{fi} \right) \]  (4.40)

For most of BPS objects considered here, they have moduli space parameter corresponding to a global phase rotation. The excitation along this direction would lead to the dyonic solutions. The Gauss law would give the equation for \( A_5 \) which is exactly the zero mode equation satisfied by the phase moduli coordinate in the background gauge of solutions without \( A_5, m'_f \) included. The parameters \( m'_f \) serve as coefficients of the excited phase moduli direction vector of the dyonic solution.

Consider a vortex-monopole composite with \( N = N_f = 2 \) in a color-flavor locking phase with \( m_1 < m_2 \). One can impose additional BPS condition on electric charge section without breaking any additional supersymmetry. One has to solve the above Gauss law which can be solved in principle in this monopole-vortex background. The result describes a composite of D1-fundamental strings connecting D3 branes, which means that the monopole carries electric charge. However, the \( A_5 \) would approach exponentially vacuum expectation value away from the monopole region, implying that the electric charge is shielded by the Higgs field. For two flavor case, one can choose \( A_5 \sim A_4 \) up to constant shift as \((m_f, m'_f)\) lies along a line. Note that \( E_Q \sim (\Delta m')^2 \) and \( Q_2 - Q_1 \sim \Delta m' \), and so the relative flavor charge fixes \( m'_2 - m'_1 \) as in the dyons in Coulomb phase.

When \( N_f \geq 3 \), D7 branes does not need to lie on a line as three points given by the mass parameters do not lie along a line in general. In this case one could have a web of D1, F1 and \((p,q)\) strings\[28\]. For example consider \( N = N_f = 3 \) in the color-flavor locking phase. If the D7 branes are separated from each other and lie on almost straight line, one can imagine a D1 string interpolating two D3 branes at the end. When we introduce the fundamental strings connecting, say first and second D3 branes, the resulting configuration would be a vortex string where there are two fundamental
monopoles attracted to each other, but the Coulomb repulsion due to the electric charge in short distance keeps them away from each other. This is quite similar to the corresponding configuration in the Coulomb phase. The key difference would be that in the Higgs phase there may be no upper bound on F1 string numbers as the electric repulsion would be shielded in large separation.

It is straightforward to extend this to situations of multiple domain walls. Consider $N = 2$, $N_f = 3$ with two domain walls interpolating $m_1, m_2$ by first D3 and $m_2, m_3$ by second D3 ($m_1 < m_2 < m_3$). If we turn on $m'_2$ slightly, these two domain walls are attracted, and it is balanced by giving them electric charges proportional to $m'_2$ distributed on their world volume. This would be web-like structure of D3 branes and sheet of fundamental strings, attached to D7 branes.

Another dyonic BPS configuration is possible. Start with a 1/2 BPS domain wall of a single D3 brane, interpolating two D7 branes in position. Fundamental strings connecting two D7 branes at the wall generates the electric dipole on D3 brane. Two ends of the dipole are shielded by the Higgs field of different flavor, and so the configuration has the Higgs charge. One needs to solve the Gauss law in the domain wall background. From the domain wall world sheet point of view, the fundamental F1 string appears as a charge of phase or magnetic flux on effective 2+1 dimensional theory. Uniform charge configuration would corresponds to uniform magnetic flux configuration on effective 2+1 dimensional theory.

In our BPS equation there is additional parameter $\varphi$. To see its role in $N = 1, N_f = 2$ with $\zeta^a = v^2 \delta_{a3}$, $A_5 = m'_f = 0$, let us consider the domain wall solution with 2, 4 directions mixed. With only dependence on $x^1$ and $x^3$ and $A_1 = A_2 = A_3 = 0$, $\eta = \alpha = -1$, $\theta = 0$, BPS equations (3.24) and (3.25)
for $A_4$ become

\[
(\partial_3 \cos \varphi - \partial_1 \sin \varphi)A_4 = \frac{1}{2}(v^2 - \sum_f |q_{f1}|^2),
\]

\[
(\partial_3 \cos \varphi - \partial_1 \sin \varphi)q_{f1} + q_{f1}(A_4 - m_f) = 0
\]

\[
(\partial_3 \sin \varphi + \partial_1 \cos \varphi)A_4 = 0, \quad (\partial_3 \sin \varphi + \partial_1 \cos \varphi)q_{f1} = 0 \quad (4.41)
\]

This corresponds to a spatial rotation in $(x^1, x^3)$ plane. The origin of this fact can be traced back to the correlation between $(x^2, x^4)$ and $(x^1, x^3)$ in the spinor projection conditions.

## 5 1/8 BPS Objects in Theories with Product Gauge Groups

While we found 1/8 BPS equations which seems to be general up to six dimensional Lorentz boost and $SU(2)_R$ symmetry, it is not clear whether 1/8 BPS configurations are allowed. After the dimensional reduction to 3+1 dimensions with two general angle parameters, one cannot make arbitrary six dimensional rotation, especially $F_{45} = 0$ in $U(1)$ theory. While we are interested in the general characteristics of 1/8 BPS configurations, if any exists, it seems very hard to solve the BPS equations.

Let us start with a theory with a simple gauge group, say, $U(N)$. To find out what the characteristics of 1/8 BPS configurations are, let us start with BPS configuration of constant field strength with zero matter expectation value. From BPS equations for the gauge fields (3.24) for the constant field strength, we can make $SU(2)_R$ rotation to put the FI parameter to 3-th direction and $SU(2)$ spatial rotation in $x^1, x^2, x^3$, which rotates both $\epsilon_i$ and the gauge field strength $F_{\mu\nu}$ with $\mu, \nu = 1, 2, 3, 4$. From this one can see that the constant field configuration is at most 1/4 BPS configuration.

Inhomogeneous BPS field configuration can be obtained by extracting magnetic fluxes from the system. To see whether 1/8 BPS configurations
are possible when the field configuration is inhomogeneous in space, we ask whether 1/8 BPS perturbation arises in 1/4 BPS homogeneous background\cite{29}.

Let us start with a $U(1)$ gauge theory on $3 + 1$ dimension with single flavor. Let us start with a 1/4 BPS configuration which is homogeneous in space and time with $A_0 = A_5$ and $\eta = \alpha = -1$ with $\theta = \varphi = 0$. The FI term becomes $D^a = e^2 v^2 / 2 \, \delta_{a3}$ and and we choose the constant 1/4 BPS field strengths to be

$$F_{12} = \frac{e^2 v^2}{2} a, \quad F_{34} = \frac{e^2 v^2}{2} (1 - a), \quad F_{23} = \frac{e^2 v^2}{2} b, \quad F_{14} = -\frac{e^2 v^2}{2} b \quad (5.42)$$

with constants $a, b$. This is a generalization of many previously known homogenous solutions. The homogeneous BPS configuration in $U(1)$ Higgs model with single Higgs field represents the uniform distribution of vortices on plane, which has the critical total magnetic flux\cite{29}. In $SU(2)$ gauge theory, one could have magnetic monopole sheet or homogenous field configuration with uniform instanton density. The energy density is then

$$\mathcal{E} = \frac{e^2 v^4}{4} \left( 1 + b^2 - a(1 - a) \right) \quad (5.43)$$

In four dimensions, the contribution from the intersection of $F_{12}$ and $F_{34}$ can decrease the tension when $0 < a < 1$ and can be regarded as an anti-selfdual instanton part with the negative energy, which can be regarded as a bound energy of two uniform magnetic flux. Note that the minimum energy is positive.

In 3+1 dimensions, it represents the bound energy of a domain wall and infinite number of vortex strings penetrating domain walls. The number of flavors does not play any role. For $b > 0$ and $a$ not in this interval induces self-dual instanton density which contributes positive energy. Note that there are critical total flux $e^2 v^2 / 2$ in our unit. From the brane point of view, the above BPS solution induces D3 branes with homogeneous field on its world sheet, tilted with respect to D7 branes.
We want to see whether there is any 1/8 BPS deformation of this homogeneous configuration. The BPS equation implies that there should be nonzero \( q_i, i = 1, 2 \) for 1/8 BPS configurations, which we regard as a small perturbation. (Here we drop flavor index as there is only one flavor.) We solve the 1/8 BPS equation by the perturbation expansion with \( \beta = -1 \). To the first order we first solve the matter BPS equation in the uniform background,

\[
D_1 q_j \sigma^1_{ji} + D_2 q_j \sigma^2_{ji} + D_3 q_j \sigma^3_{ji} - iD_4 q_i = 0, \quad (5.44)
\]

We choose the gauge

\[
A_1 = 0, \quad A_2 = \frac{e^2 v^2}{2} (ax^1 - bx^3), \quad A_3 = 0, \quad A_4 = \frac{e^2 v^2}{2} ((1 - a)x^3 - bx^1) \quad (5.45)
\]

The above equation is satisfied if

\[
\partial_1 q_i + \frac{e^2 v^2}{2} x^1 q_j (a\sigma^3 - b\sigma^1)_{ji} = 0, \quad \partial_3 q_i + \frac{e^2 v^2}{2} x^3 q_j (b\sigma^1 + (1 - a)\sigma^3)_{ji} = 0 \quad (5.46)
\]

One can convince oneself that only \( q_1 \) becomes normalizable along both \( x^1 \) and \( x^3 \) directions for \( b = 0 \) and \( 0 < a < 1 \) while \( q_2 \) is not normalizable at all. For 1/8 BPS deviation, we need both normalizable \( q_1 \) and \( q_2 \) modes to start the perturbative approach and so there is no 1/8 BPS deviation from the 1/4 BPS configuration. The BPS equation for the gauge fields indicate the second order effect of the \( q_1 \) perturbation reducing the total magnetic flux and instanton or monopole number. Thus one can guess that the above homogeneous configuration, while remaining 1/4 BPS, is continuously connected to the two intersecting flux sheet along \( x^1 - x^2 \) and \( x^3 - x^4 \) plane with finite magnetic monopole charge and negative bound energy. In the brane picture, the end result would be the intersection of D3 brane domain wall and D1 string.

While the above analysis does not provide clear picture about the existence of 1/8 BPS configurations in 8 supersymmetric \( U(N) \) gauge theories, it suggests that 1/8 BPS configurations are unlikely.
Now consider a theory with $U(1) \times U(1)$ gauge group with fundamental matter fields in each gauge group and also many bi-fundamental matter fields of charge $(+1, -1)$. Let assume that two FI parameters are not parallel and so, say, $\zeta^{(1)a} = \delta_{a3}$ and $\zeta^{(2)a} = \delta_{a1}$. (Here we put the proportional numbers and electric charges to be one for simplicity.) If there is no bi-fundamental matter fields, two theories are not interacting and so it is obvious that there can be 1/8 BPS configurations. They can be made of 1/4 BPS configurations of each gauge group but they are not aligned and so break the supersymmetry further to 1/8. Even when bi-fundamental fields exist, such 1/8 BPS configurations are possible if bi-fundamental field has zero expectation value.

To see whether bi-fundamental matter field can develop any nontrivial expectation value, let us start with 1/8 BPS homogeneous configuration in this theory of two product gauge group,

$$
F_{12}^{(1)} = a, \quad F_{34}^{(1)} = 1 - a \quad (5.47)
$$
$$
F_{23}^{(2)} = b, \quad F_{14}^{(2)} = 1 - b \quad (5.48)
$$

The energy density of the configuration becomes

$$
\mathcal{E} = \frac{1}{4}(2 - a(1 - a) - b(1 - b)) \quad (5.49)
$$

With the gauge

$$
A_2^{(1)} = ax^1, \quad A_1^{(1)} = (1 - a)x^3, \quad A_2^{(2)} = -bx^3, \quad A_1^{(2)} = (1 - b)x^1 \quad (5.50)
$$

The interesting question is whether there exists a nonzero mode for the bi-fundamental field $q_i$, whose BPS equation is satisfied if

$$
\partial_1 q_i + x^1 q_j (a \sigma^3 - (1 - b) \sigma^1)_{ji} = 0 \quad (5.51)
$$
$$
\partial_3 q_i + x^3 q_j ((1 - a) \sigma^3 - b \sigma^1)_{ji} \quad (5.52)
$$

The normalizable solution along $x^1, x^3$ direction is possible if $a = b = 1/2$, in which case two matrices are proportional to each other and so can be
exponentiated easily. Once we found this normalizable zero mode, we can feed it to the BPS equation for the gauge field, which leads to the second order perturbation, which reduces the sum of the magnetic fluxes. Of course there will be also nontrivial BPS deformation of fundamental matter field for each gauge group. One can imagine the continuous deflation of the total flux would lead to some sort of intersecting U(1) magnetic vortex sheets, while remaining 1/8 BPS. From 1/4 BPS case, one can see that first U(1) vortex line along $x^3$ direction meets a first U(1) domain parallel to the $1 - 2$ plane. The second U(1) vortex line along $x^1$ direction meets a second U(1) domain wall parallel to the $2 - 3$ plane. Together they would remain 1/8 BPS. In addition, there would be nontrivial bi-fundamental matter field in this 1/8 BPS configuration, making two configurations to be connected together.

6 Nonexistence of BPS Vortices

Most of the analysis on solitons so far have been done when $N_f \geq N$. Especially there would be no supersymmetric vacua if $N_f < N$ without adjoint hypermultiplet. When $N_f < N$, the adjoint hypermultiplet plays a crucial role for supersymmetric vacua to exist. When $N = 2, N_f = 1$, the explicit vacuum solution modulo local gauge transformations is known\cite{20}. At the vacuum the scalars in vector multiplet $(A_4, A_5) = (m_1, m'_1)$, proportional to the identity matrix. With adjoint hypermultiplet, the vacuum equation $D^a = 0$ is the ADHM condition on two instantons in noncommutative $U(1)$ theory, and the moduli space metric becomes the Eguchi-Hanson space. It is depending on eight parameters, four of which are the position of the center of mass of two D3 branes in D7 branes, and so flat and does not affect our analysis. There are additional four parameters which indicates the relative distance and phase between two D3 branes in D7 branes. Due to the FI term,
there would be Higgs condensation on D3 branes. Explicitly,

\[
\langle \bar{y}_1 \rangle = w_1 + \frac{z_1}{2} \begin{pmatrix} 1 & \sqrt{\frac{2a}{a}} \\ 0 & -1 \end{pmatrix}, \quad \langle y_2 \rangle = w_2 + \frac{z_2}{2} \begin{pmatrix} 1 & \sqrt{\frac{2a}{a}} \\ 0 & -1 \end{pmatrix}
\]

(6.53)

\[
\langle \bar{q}_1 \rangle = v \left( \sqrt{\frac{1-b}{1+b}} \right), \quad \langle q_2 \rangle = 0
\]

(6.54)

where \(a = (|z_1|^2 + |z_2|^2)/(2v^2)\) and \(b = \sqrt{a^2 + 1} - a\). The vacuum moduli space is characterized by four complex parameters \(w_i, z_i\). The parameter \(w_i\) denotes the location of the center of mass points of two D3 branes on D7 background and the parameter \(z_i\) denotes the relative position.

We know there are BPS multi-vortex solutions when \(N = N_f = 1\). The question is whether any BPS vortex solitons exist when \(N = 2, N_f = 1\). Suppose we put a single D1 string on one of D3 branes when two D3 branes are in infinite separation. Clearly it is BPS. As we change vacuum moduli parameters so that two D3 branes are almost on top of each other, we may expect that there would be 1/2 BPS vortex solutions. To see whether it is true, we look at a consistent ansatz.

Rather the surprise appears when two D3 branes are on top of each other, or when the vacuum moduli is at minimum two sphere of Eguch-Hanson space. In this case the consistent ansatz becomes

\[
\bar{y}_1 = \begin{pmatrix} 0 & Z \\ 0 & 0 \end{pmatrix}, \quad y_2 = 0, \quad \bar{q}_1 = \begin{pmatrix} 0 \\ Q_2 \end{pmatrix}, \quad q_2 = 0, \quad A_1 + iA_2 = \text{diag}(A, B)
\]

(6.55)

The BPS equation get simplified to be ( \(\partial = \frac{1}{2}(\partial_1 - i\partial_2)\))

\[
\partial Z - i(A - B)Z = 0, \quad \partial Q_2 - iBQ_2 = 0,
\]

(6.56)

\[
-i(\bar{\partial}A - \partial A) = v^2 - |Z|^2,
\]

(6.57)

\[
-i(\bar{\partial}B - \partial B) = v^2 + |Z|^2 - |Q|^2.
\]

(6.58)

Asymptotic value of \(|Z|^2\) and \(|Q|^2\) are \(v^2\) and \(2v^2\), respectively. The above
BPS equations can be combined to

\[-\partial_i^2 \ln |Z/Q|^2 = v^2 - |Z|^2 \quad (6.59)\]

\[-\partial_i^2 \ln |Q|^2 = v^2 + |Z|^2 - |Q|^2 \quad (6.60)\]

The BPS energy is determined by \(\frac{v^2}{2}(F_A + F_B) = 2v^2 - |Z|^2\). The vorticity of \(Z\) and \(Q\) are \(l_1, l_2\), then the flux \(\int d^2 x (F_A - F_B) = 2\pi l_1 > 0\) and \(\int d^2 x F_B = 2\pi l_2 > 0\). The \(\int d^2 x F_A = 2\pi (l_1 + l_2)\) and the energy is \(\pi v^2 (l_1 + l_2)\). From examining the above equations, one can easily draw the fact that there is no solution with \(l_1 = 0, l_2 > 0\) or \(l_1 > 0, l_2 = 0\) or \(l_1 = l_2 > 0\). The only possibility is \(l_1 - 1 \geq l_2 \geq 1\). As we move D3 branes apart, it suggests that there is no BPS configurations possible for vortices with vorticity 1 or 2 even D3 branes are apart. Assuming that the continuity of the BPS configurations here as we do not see any critical separation between D3 branes matter, there seems to be only one logical conclusion, that is, that two D3 branes with any parallel D1 string on them become repulsive. That means there is no BPS configuration with any vorticity and finite separation. This seems to be only consistent result. It would be interesting to verify this conjecture.
