Abstract. We consider the classification problem for rank 4 premodular categories. While no new categories are uncovered a formula for the 2nd Frobenius-Schur indicator of a premodular category is determined and the classification of rank 4 premodular categories is completed.

1. Introduction

The theory of fusion categories is a natural generalization of representation theory—not only of finite groups, but of Lie groups and Hopf algebras and so, in some sense, their classification began with the classification of groups and their representations. At the time of this writing, a complete classification has only been completed for rank 2 fusion categories [O1]. While the classification problem for fusion categories is largely believed to be intractable, several natural structures can be imposed on fusion categories to make them more amenable to study.

One such structure is that of braiding. This gives rise to a kind of commutativity and indeed forces the underlying Grothendieck semiring to be commutative. On the other hand, one might expect that the two natural notions of dimension in the theory coincide, leading to pseudo-unitary fusion categories. If study is restricted to pseudo-unitary fusion categories, then it is known that the category is also spherical [ENO]. The appearance of a spherical structure is perhaps not surprising as there are no known examples of non-spherical fusion categories at this time.

Even with the addition of these structures, a full classification is believed to be out of reach as it would include a classification of finite groups. However, these categories admit a stratification by degeneracy of the $S$-matrix into symmetric, properly pre-modular, and modular categories. The representation categories fall naturally in the symmetric case and in fact completely fill it out [Deligne]. At the other end of the spectrum, a large amount of work has gone into understanding modular categories spurred by their relationship to rational conformal field theories, quantum computation, link invariants, and 3-manifold invariants [Wang][Turaev][BK]. However, recently premodular categories have been shown to provide the algebraic underpinnings of (3 + 1)-dimensional topological quantum

Date: May 10, 2014.
field theories and thereby govern topological insulators and some high–$T_c$ superconductors \cite{WW}. In addition to their innate uses, premodular categories give rise to modular categories through the double construction.

Classification of premodular categories has been completed for rank 2 and 3 \cite{O1,O2} and in this paper we extend the classification to rank 4. To do this, a formula for the $2^{nd}$ Frobenius-Schur indicator is determined in terms of the premodular datum. We will begin by reviewing the theory of modular and premodular categories. Having dispensed with these preliminaries, a formula for the $2^{nd}$ Frobenius-Schur indicator will be derived in the premodular setting. As an application of this indicator, the rank 4 premodular categories will then be classified. In conjunction with \cite{RSW}, this will complete the classification of rank 4 premodular and modular categories. Finally, Appendix A will contain an incomplete classification of rank 5 modular categories which was required for the determination of rank 4 premodular categories.

2. Preliminaries

A premodular category $\mathcal{C}$ is a braided, balanced, and fusion category. Furthermore, if the $S$-matrix is invertible then $\mathcal{C}$ is said to be modular. Every premodular category $\mathcal{C}$ is a ribbon category and as such enjoys a graphical calculus. A brief account of this calculus in addition to some salient algebraic relations will be given and further detail can be found in \cite{BKi,Kitaev,Turaev}.

2.1. Pivotal Structure and Dimensions.

By virtue of being a fusion category, $\mathcal{C}$ is semisimple and we will denote the isomorphism classes of the simple objects by $\mathbb{I} = X_0, \ldots, X_{n-1}$ where $n$ is known as the rank of $\mathcal{C}$. Furthermore, $\mathcal{C}$ is balanced and hence pivotal. This structure manifests itself through a duality $\ast$ acting by $X_a^* = X_{a^*}$. Such a duality induces an involution on the labeling set for the simple objects and can be encoded by the charge conjugation matrix $C_{ab} = \delta_{ab^*}$. Graphically, a nontrivial simple object $X_a$ is denoted by an upward arrow and its dual by a downward arrow,

\[
\begin{align*}
\begin{array}{c}
\uparrow \\
a
\end{array} & \quad \begin{array}{c}
\downarrow \\
a
\end{array} \\
\end{align*}
\]

For the trivial object, $X_0 = \mathbb{I}$, no arrow is drawn. Note that for a self-dual object the arrow may be safely omitted. The pivotal structure of $\mathcal{C}$ further provides a collection of evaluation and co-evaluation maps

\[
\begin{align*}
ev_X : X^* \otimes X & \to \mathbb{I} \\
coev_X : \mathbb{I} & \to X \otimes X^*
\end{align*}
\]
These maps are given by the cup and cap
\[ coev = \begin{array}{c} \bigcirc \\ \bigcirc \end{array} \quad ev = \begin{array}{c} \bigcirc \\ \bigcirc \end{array} \] (2.3)
Compatibility of such maps give rise to the allowed graphical moves:
\[ \begin{array}{c} \bigcirc \\ \bigcirc \end{array} = \begin{array}{c} \bigcirc \\ \bigcirc \end{array} = \begin{array}{c} \bigcirc \\ \bigcirc \end{array} \] (2.4)
A pivotal category also comes equipped with a family of natural isomorphisms
\[ j_X : X \to X^{**} \] . The presence of these maps give rise to two canonical traces called
left and right pivotal traces [NS1]. In a spherical category, these traces coincide
and so, for \( f \in \text{End}_C(X) \), one simply writes \( \text{Tr}_C(f) \). By the coherence theorems,
it is known that every premodular category is equivalent to a strict premodular
category and so we will, without loss of generality, restrict our attention to strict
categories. One benefit of focusing on strict categories is that the isomorphisms
\( j_X \) can be removed, which greatly simplifies the graphical calculus. For instance, tak-
ing the trace of \( \text{id}_X \) allows one to define dimension of \( X_a \) and the global dimension,
\( D^2 \). These dimensions are graphically given by
\[ \text{dim}(X_a) = d_a = \begin{array}{c} \bigcirc \\ \bigcirc \end{array} , \quad D^2 = \text{dim}(C)^2 = \begin{array}{c} \bigcirc \\ \bigcirc \end{array} := \sum_{b \in \text{Irr}(C)} d_b \begin{array}{c} \bigcirc \\ \bigcirc \end{array} \] (2.5)

2.2. Fusion and Splitting Spaces.
\( \mathbb{C} \)-linearity of \( C \) endows \( \text{Hom}_C(V,W) \) with the structure of a complex vector space
for all \( V \) and \( W \) in \( C \). However, certain families of Hom-spaces are distinguished
due to semisimplicity, they are the fusion spaces \( V^{ab}_c = \text{Hom}_C(X_a \otimes X_b, X_c) \) and
the splitting spaces \( V_{ab}^c = \text{Hom}_C(X_c, X_a \otimes X_b) \). In the course of this work a basis
of the splitting space will be denoted by \( \{ \psi_{ab}^{ci} \} \) and the dual basis of the fusion
space is given by \( \{ \psi_{c,ij}^{ab} = (\psi_{ab}^{ci})^\dagger \} \). These bases are graphically depicted by
\[ \begin{array}{c} \begin{array}{c} \bigcirc \\ \bigcirc \end{array} \\ \begin{array}{c} \bigcirc \\ \bigcirc \end{array} \end{array} \text{ and } \begin{array}{c} \begin{array}{c} \bigcirc \\ \bigcirc \end{array} \\ \begin{array}{c} \bigcirc \\ \bigcirc \end{array} \end{array} \] (2.6)
respectively. The normalization of these bases will always be such that
\[ \theta(a, b, c) \delta_{ij} = \begin{array}{c} \begin{array}{c} \bigcirc \\ \bigcirc \end{array} \\ \begin{array}{c} \bigcirc \\ \bigcirc \end{array} \end{array} \] (2.7)
where $\theta(a, b, c) = \sqrt{d_a d_b d_c}$ is the theta symbol. Further note that this normalization is consistent with the graphical dimensions given in equation (2.5) i.e. $b = a^*$ and $c = 0$.

The dimension of the fusion space $\text{Hom}_C(X_a \otimes X_b, X_c)$ is called a fusion coefficient and is denoted by $N^c_{ab}$. The fusion coefficient, $N^c_{ab}$ gives the multiplicity of $X_c$ appearing in $X_a \otimes X_b$. Furthermore, this particular symbol appears in the decomposition of $id_{X_a \otimes X_a}$ as

$$
\begin{align*}
\sum_{c \in \text{Irr} C} \sum_{i \in V^c a} \sum_{j \in V^c c} d_c \theta(a, b, c) a_i b_j \sum_{c \in \text{Irr} C} \sum_{i \in V^c a} \sum_{j \in V^c c} d_c \theta(a, b, c) a_i b_j
\end{align*}
$$

(2.8)

The fusion coefficients are generally collected into fusion matrices $(N_a)_{bc} = N^c_{ab}$ and furnish a representation of the Grothendiek semiring $Gr(C)$ [HR]. Since the fusion coefficients are nonnegative integers, the Frobenius-Perron Theorem can be applied to deduce the existence of a largest eigenvalue of $N_a$, such an eigenvalue is called the Frobenius-Perron dimension or FP-dimension of $X_a$ and is denoted $\text{FPdim}(X_a) = \dim(X_a)$ for all $a$. The global FP-dimension of the category is defined by $\text{FPdim}(C)^2 = \sum_a \text{FPdim}(X_a)^2$. If the global FP-dimension is an integer, the category is said to be weakly integral and if $\text{FPdim}(X_a) \in \mathbb{Z}$ for all $a$ then one says $C$ is integral. Finally, duality and braiding endow the fusion matrices with the following symmetries [BK]:

$$
\begin{align*}
N^c_{ab} &= N^c_{ba} = N^{b^*}_{ac^*} = N^{c^*}_{a^* b^*}, \\
N^{0^*}_{a^* b^*} &= 1, \quad N_a^* = N_a^T, \quad N_a N_b = N_b N_a.
\end{align*}
$$

(2.9)

2.3. Spherical Structure.

The spherical structure gives rise to canonical elements $\theta_a \in \text{End}_C(X_a)$ called twists. Since $\text{End}_C(X_a)$ is one dimensional, the twists are scalar multiples of the identity, also denoted $\theta_a$. Graphically, we have

$$
\begin{align*}
\theta_a &\quad = \quad \bigcirc
\end{align*}
$$

The celebrated Vafa Theorem tells us that these twists are roots of unity [Vafa]. For convenience, the twists are collected into the diagonal matrix $T_{ab} = \delta_{ab} \theta_b$ called the $T$-matrix.

2.4. Braiding.

The braiding in $C$ is given by elements $R_{ab} \in \text{Hom}_C(X_a \otimes X_b, X_b \otimes X_a)$. Coupling these maps with the splitting spaces, one can define the $R$-matrices
\[(R_c)_{ab} = R_{ca}^{ab}, \text{ where } R_{ca}^{ab} \text{ is obtained by "braiding } X_a \text{ with } X_b \text{ in the } X_c \text{ channel."} \]

In fact, the bases of the splitting space \( V_{ab}^c \) can be chosen to diagonalize \( R_{ca}^{ab} \) by

\[R_{ca}^{ab} \psi_{c,i}^{ab} = R_{ca}^{ab} \psi_{c,i}^{ab} \] [Kitaev]. Pictorially, this is given by

\[
\begin{array}{c}
\begin{array}{c}
\text{a} \\
\downarrow
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\text{c} \\
\uparrow
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\text{b} \\
\uparrow
\end{array}
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\text{a} \\
\downarrow
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\text{c} \\
\uparrow
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\text{b} \\
\uparrow
\end{array}
\end{array}
\end{array}
\]

These braidings give rise to a family of natural isomorphisms \( c_{ab} = R_{ba} R_{ab} \) in \( \text{End}_C (X_a \otimes X_b) \) which can be traced to define the \( S \)-matrix

\[\tilde{s}_{ab} = \text{Tr}_C (c_{ab}) = \begin{array}{c}
\begin{array}{c}
\text{b} \\
\uparrow
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
\text{a} \\
\downarrow
\end{array}
\end{array}\] (2.10)

2.5. **Algebraic Identities.**

The \( S \)-matrix is highly symmetric and, in fact we have

\[\tilde{s}_{a^* b^*} = \tilde{s}_{ab} = \tilde{s}_{ba} = \tilde{s}_{a^* b^*}, \quad \tilde{s}_{a 0} = d_a. \] (2.11)

In the course of this work the tuple \( (\tilde{S}, T, N_0, \ldots, N_n) \) will be referred to as premodular datum. Perhaps not surprisingly, the matrices comprising premodular datum are strongly related. For instance, an elementary application of the graphical calculus leads to the balancing relation [BK]

\[\tilde{s}_{ab} = \theta_a^{-1} \theta_b^{-1} \sum_c N_{c a}^b d_c. \] (2.12)

Additionally, one can show that the columns of \( S \)-matrix are eigenvectors of the fusion matrices. In a modular category, this leads to the well-known Verlinde Formula, while in the premodular setting it is shown in [Müger] that

\[\tilde{s}_{ab} \tilde{s}_{ac} = d_a \sum_\ell N_{c a}^\ell d_c. \] (2.13)

It can further be shown that the \( S \)- and \( T \)-matrices are related by

\[
\begin{aligned}
(\tilde{S}T)^3 &= p^+ \tilde{S}^2, \\
(\tilde{S}T^{-1})^3 &= p^- \tilde{S}^2 C.
\end{aligned}
\] (2.14)

where \( p^\pm \) are the Gauss sums:

\[p^\pm = \sum_a \theta_a^\pm d_a^2. \] (2.15)
If \( \det(\tilde{S}) \neq 0 \) then \( C \) is said to be modular and the additional identities
\[
\tilde{S}\tilde{S}^\dagger = D^2 \mathbb{I} \quad \text{and} \quad p^+ p^- = D^2,
\]
are acquired, from which it is clear that \( \tilde{S} \) and \( T \) furnish a projective representation of the modular group \( \text{SL}(2, \mathbb{Z}) \).

\( C \) is said to be symmetric if \( \tilde{s}_{ab} = d_a d_b \) for all \( a \) and \( b \). One can view symmetric categories as completely degenerate premodular categories while modular categories are completely nondegenerate. It is between these two extremes that we will be focusing our attention and so we define a properly premodular category \( C \) to be a premodular category that is neither symmetric nor modular. In this way, symmetric, properly premodular, and modular categories partition the class of premodular categories.

2.6. The Müger Center and Finiteness.

The braiding can be used to define the Müger center of a premodular category by \cite{Müger1}
\[
C' = \{ X \in C \mid c_{X,Y} = id_{X \otimes Y}, \forall Y \in C \}.
\]
(2.17)
The elements of the center are often called central or transparent \cite{Müger1, Bruguières}.

This center constitutes a full symmetric ribbon subcategory of \( C \) which is trivial if and only if \( C \) is modular. In fact, if \( C \) is not modular then some column of the \( S \)-matrix is a multiple of the first \cite{Bruguières}. Thus a premodular category \( C \) is symmetric if \( C = C' \), \( C \) is modular if \( C' = \{ \mathbb{I} \} \), and \( C \) is properly premodular otherwise.

Given these abstract constructions one might wonder if premodular categories exist and indeed they do; for instance, quantum groups lead not only to modular, but also to properly premodular categories \cite{Rowell}. Given their existence, a classification program has been taken up. In \cite{O1} and \cite{O2}, Ostrik has classified all fusion categories of rank 2 and all premodular categories of rank 3. However, one should tread lightly as it is not yet known if low rank classification is well defined, that is:

**Question 1.** Are there finitely many premodular categories of fixed rank up to equivalence?

In the modular setting the affirmative answer is known as Wang’s Conjecture \cite{RSW}, while in the fusion setting, this question was first asked by Ostrik \cite{O1}. While Wang’s Conjecture is still an open problem, it has been proven in the restricted cases:

---

\(^1\)In the course of this work, simple objects in the Müger center will be indexed by greek letters to distinguish them from simple objects in \( C \) which will be indexed by lower case latin letters.
1. \( \text{FPdim} (C) \) is bounded.
2. \( \text{rank} (C) \leq 4. \)
3. \( C \) is weakly integral.

To this author’s knowledge such a conjecture for premodular categories has not appeared in the literature. As we will see below, there are only finitely many premodular categories of rank four. Coupled with the results of [O1] [O2], this implies that there are only finitely many premodular categories of rank \( < 5 \). It is possible that the finiteness of premodular categories can be reduced to Wang’s Conjecture via the double construction. Indeed, every premodular category \( C \) gives rise to a modular category \( \mathcal{Z} (C) \) by passing to its Drinfeld center. It is not known if there is a bound on the rank of \( \mathcal{Z} (C) \) strictly in terms of the rank of \( C \). Without such a rank bound a proof of Wang’s Conjecture would not imply the same for premodular categories. However, some progress in bounding the rank of the double has been made. For instance, in [Müger2], it was shown that the rank of \( \mathcal{Z} (C) \) is bounded in terms of the fusion coefficients of \( C \), and Etingof has produced a bound for the rank of \( \mathcal{Z} (\text{Rep} (G)) \) for finite groups \( G \) strictly in terms of the rank of \( \text{Rep} (G) \) [Eti]. While this problem will not be seriously addressed any further in this work, we find it to be an interesting question.

3. Frobenius-Schur Indicators

As alluded to in the literature e.g. [DGNO], the study of fusion categories is the correct generalization of the study of the representation theory of finite groups. Each finite group, \( G \), gives rise to a fusion category whose objects are the representations of \( G \) and whose morphisms are intertwiners [DGNO]. With this connection, it is natural to ask if the techniques used in the study of finite group representations can be generalized to arbitrary fusion categories and often they can. For instance, the class equation was generalized in [ENO], and a rigorous study of Frobenius-Schur indicators was undertaken in [NS1] [NS2].

In the classical theory of the representations of finite groups one can form the \( n \)-th Frobenius-Schur indicator from the characters for any \( n \in \mathbb{N} \). The 0-th Frobenius-Schur indicator gives the dimension of the representation, the 1-st indicator detects if the representation is the trivial representation. The 2-nd indicator of an irreducible representation is 1, 0, or \(-1\) depending on if the representation is real, complex, or quaternionic.

The 2-nd Frobenius-Schur indicator in the context of fusion categories was first computed by physicists studying rational conformal field theories [Bantay]. The study of Frobenius-Schur indicators was furthered by Richard Ng and Peter Schauenberg who applied the graphical calculus and categorical considerations to derive graphical expressions for the \( n \)-th Frobenius-Schur indicators of pivotal, spherical, and modular categories. In the modular case, they recovered Bantay’s result and found
similar formulas for computing the $n^{th}$ indicator of a modular category in terms of the modular datum. If the modularity assumption is dropped it is not known how to compute the $n^{th}$ indicator strictly in terms of the premodular datum; that is without recourse to the graphical calculus. In this section, we will determine the following formula for the 2nd Frobenius-Schur indicator of a premodular category:

$$\nu_2 (X_a) = \frac{1}{D^2} \sum_{b,c} N_{bc}^a d_b d_c \left( \frac{\theta_b}{\theta_c} \right)^2 - \theta_a \sum_{\gamma \in C \setminus \{I\}} d_{\gamma} \text{Tr} \left( R_{\gamma}^{aa} \right).$$

If the modularity condition is enforced, one sees that $C' = \{I\}$ and so the above formula recovers Bantay’s result.

Examination of Ng and Schauenberg’s proof presented in \cite{NS1} reveals that modularity is only used indirectly when invoking \cite{BK1} Corollary 3.1.11. This corollary can be modified to give a starting place for computing the 2nd indicator in the premodular setting.

**Proposition 3.1.** If $C$ is premodular and $X_a$ is self-dual then

$$\frac{d_a}{D^2} = \sum_{b,c,i} d_b d_c \theta(a,a,c) \left( \frac{\tilde{s}_{bc}^2}{\theta(a,a,c)} \right)_{0c} \theta(a,a,c)$$

Proof. Applying equation \eqref{2.8} and \cite{BK1} Lemma 3.1.4 we have

$$= \sum_{b,c,i} d_b d_c \tilde{s}_{bc} \theta(a,a,c) \left( \frac{\tilde{s}_{bc}^2}{\theta(a,a,c)} \right)_{0c} \theta(a,a,c)$$

$$= \sum_{c \neq 0, i} \left( \frac{\tilde{s}_{bc}^2}{\theta(a,a,c)} \right)_{0c} \theta(a,a,c)$$
Since the columns of the columns of the $S$-matrix are eigenvectors of the fusion matrices we know that $(s^2)_{\gamma,0} = d_\gamma D^2$ if $X_\gamma \in C'$ and 0 otherwise; this observation gives the desired result.

Recall from [NS1] that the $n^{\text{th}}$ Frobenius-Schur indicator is defined by $\nu_n(X) = \text{Tr} \left( E_X^{(n)} \right)$, where $E_X^{(n)}$ is given by

\[
E_X^{(n)} : \begin{array}{c}
\includegraphics[width=0.5\textwidth]{diagram1.png}
\end{array} \mapsto \begin{array}{c}
\includegraphics[width=0.5\textwidth]{diagram2.png}
\end{array}
\]

Applying techniques from [NS1] and our bases for the splitting and fusion spaces, to this definition, we find that if $X_a$ is self-dual, then the 2$^{\text{nd}}$ Frobenius-Schur indicator is given by

\[
\nu_2(X_a) = \frac{\theta_a}{d_a} \sum_{b,c} N_{bc} d_b d_c \left( \frac{\theta_b}{\theta_c} \right)^2 - \theta_a \sum_{\gamma \in C^c \setminus I} d_\gamma \text{Tr} \left( R_a^{\gamma a} \right).
\]

**Corollary 3.2.** If $C$ is a premodular category and $X_a$ is a simple self-dual object then

\[
\nu_2(X_a) = \frac{1}{D^2} \sum_{b,c} N_{bc} d_b d_c \left( \frac{\theta_b}{\theta_c} \right)^2 - \theta_a \sum_{\gamma \in C^c \setminus I} d_\gamma \text{Tr} \left( R_a^{\gamma a} \right).
\]

**Proof.** The proof proceeds by applying Proposition 3.1 to equation (5.1) and then making use of the graphical calculus. To simplify notation we observe that since $X_a$ is self-dual the arrow on the ribbon corresponding to this object can be safely
\[
\nu_2(X_a) \equiv \frac{\theta_a}{d_a} \frac{d_a}{D^2} - \frac{\theta_a}{d_a} \sum_{\gamma \in \mathcal{C} \setminus \{i,j\}} \sqrt{d_{\gamma}} \text{ removed.}
\]

\[
\nu_2(X_a) = \frac{\theta_a}{D^2} \sum_b \bigg( d_b \left( \frac{\theta_a}{d_a} \frac{d_a}{D^2} - \frac{\theta_a}{d_a} \sum_{\gamma \in \mathcal{C} \setminus \{i,j\}} \sqrt{d_{\gamma}} \right) + \theta_a \sum_{\gamma \in \mathcal{C} \setminus \{i,j\}} d_\gamma \text{Tr} (R_{aa}) \bigg)
\]

\[
\nu_2(X_a) = \frac{\theta_a}{D^2} \sum_{b,c,i,j} \left( d_b d_c \left( \frac{R_{aa}}{\theta (a,b,c)} \right)^2 \theta (a,b,c) \delta_{ij} - \theta_a \sum_{\gamma \in \mathcal{C} \setminus \{i,j\}} d_\gamma \text{Tr} (R_{aa}) \right)
\]

\[
\nu_2(X_a) = \frac{\theta_a}{D^2} \sum_{b,c,i,j} \left( d_b d_c \left( R_{ab} R_{ba} \right)^2 - \delta_{ij} \sum_{\gamma \in \mathcal{C} \setminus \{i,j\}} d_\gamma \text{Tr} (R_{aa}) \right)
\]
Applying equation (216) of Appendix E in [Kitaev] and noting that $(\tilde{s}^2)_{\gamma 0} = d_\gamma D^2$ for $X_\gamma \in C'$ gives

$$\nu_2 (X_a) = \frac{\theta_a^2}{D^2} \sum_{b,c,i} d_b d_c \left( \frac{\theta_c}{\theta_{a\theta_b}} \right)^2 - \theta_a \sum_{\gamma \in \mathcal{C}' \setminus \{I\}} d_\gamma \text{Tr} \left( R_{\gamma a}^{aa} \right).$$

Making use of equation (2.9) we have

$$N_{c a b} = N_{c ba} = N_{a b c}^* = N_{a c b}^*.$$ 

However, $\theta_{b^*} = \theta_b$ and $d_{b^*} = d_b$ so

$$\nu_2 (X_a) = -\theta_a \sum_{\gamma \in \mathcal{C}' \setminus \{I\}} d_\gamma \text{Tr} \left( R_{\gamma a}^{aa} \right).$$

Reindexing the first sum gives the desired result.

Since the $R$-matrices appear in this indicator, it is of limited computational use. However, one can show that the two sums of Theorem 3.2 are both rational integers.

To do this, we first recall that the Müger center of $\mathcal{C}$ is a ribbon fusion category over $\mathbb{C}$ with fusion rules and twists descending from $\mathcal{C}$. Moreover, $c_{W,V} \circ c_{V,W} = id_{V \otimes W}$ on $\mathcal{C}'$ by its definition. So applying [NS1, Proposition 6.1], we can deduce that if $X_\gamma \in \mathcal{C}'$ then $\theta_\gamma = \pm 1$. However, $\theta_{a\theta_b} R_{\gamma a}^{aa} = \pm \sqrt{\theta_c}$ and so, if $X_\gamma \in \mathcal{C}'$, we deduce that $\theta_{a\theta_b} R_{\gamma a}^{aa} \in \{\pm 1, \pm i\}$, which leads to the following corollary.

**Corollary 3.3.** If $\mathcal{C}$ is premodular and $X_a \in \mathcal{C}$ simple, then

$$\frac{1}{D^2} \sum_{b,c} N_{c a b}^* d_b d_c \left( \frac{\theta_b}{\theta_c} \right)^2$$

is real and if $X_a$ is self-dual then it is a rational integer.

**Proof.** Applying [NS1], we know that $\nu_2 (X_a) \in \{-1, 0, 1\}$. Coupling this observation with the afore mentioned fact that $\theta_{a\theta_b} R_{\gamma a}^{aa} \in \{\pm 1, \pm i\}$ for $X_\gamma \in \mathcal{C}'$, we can conclude that

$$\frac{1}{D^2} \sum_{b,c} N_{c a b}^* d_b d_c \left( \frac{\theta_b}{\theta_c} \right)^2 \in \mathbb{Z}[i].$$

However, $N_{c a b}^{\alpha} = N_{c b a}^{\alpha}$, $d_b \in \mathbb{R}$, and $\bar{\theta}_b = \theta_b^{-1}$ for all $a, b, c$. So for any $a$ we have that

$$\frac{1}{D^2} \sum_{b,c} N_{c a b}^* d_b d_c \left( \frac{\theta_b}{\theta_c} \right)^2$$

is invariant under complex conjugation.

Consequently

$$\frac{1}{D^2} \sum_{b,c} N_{c a b}^* d_b d_c \left( \frac{\theta_b}{\theta_c} \right)^2 \in \mathbb{Z}[i] \cap \mathbb{R} = \mathbb{Z}.$$

**Remark 3.4.** One can apply this corollary to show that the Müger center of a premodular category is integral as follows. Recall from [NS1 Section 6], that if $\alpha, \beta \in \mathcal{C}'$ then $\theta_{\alpha \otimes \beta} = \theta_\alpha \otimes \theta_\beta$ so $\theta_{\alpha \otimes \beta}^2 = \theta_\alpha^2 \otimes \theta_\beta^2$. Consequently,
\[ \sum_{\beta \in C'} N_{\alpha,\gamma}^\beta \theta_{\beta}^2 d_{\beta} = \theta_{\alpha}^2 \theta_{\gamma}^2 d_{\alpha} d_{\gamma} \]

which can be rearranged to give
\[ \sum_{\beta \in C'} N_{\alpha,\gamma}^\beta d_{\beta} \left( \frac{\theta_{\beta}}{\theta_{\gamma}} \right)^2 = \theta_{\alpha}^2 d_{\alpha} d_{\gamma}^2. \]

Summing over \( \gamma \in C' \) and reindexing gives
\[ \theta_{\alpha} d_{\alpha} = \frac{1}{D_{C'}^2} \sum_{\beta,\gamma \in C'} N_{\beta,\gamma}^\alpha d_{\beta} \left( \frac{\theta_{\beta}}{\theta_{\gamma}} \right)^2 \in \mathbb{Z}. \]

This is equivalent to saying that the Müger center is an integral subcategory of \( C \). Since the Müger center is a symmetric category and hence necessarily a representation category of a finite group, we know that it is integral. However, this does provide a new (to this author) route to this result.

Examination of Theorem 3 reveals that \( R_{ac} \) enters into the formula for the second indicator. Since the \( R \)-matrices involve square roots of the twists, we have that \( R_{ab} \) is a \( 2N \)-th root of unity where \( N = \text{ord} (T) \). Coupling this observation with Frobenius-Schur exponent of [NS1] motivates the following conjecture.

**Conjecture 3.5.** If \( C \) is premodular, \( X_a \) is a simple object and \( N = \text{ord} (T) \), then \( d_a \in \mathbb{Z} \left[ \zeta_{2N} \right] \).

This result is reminiscent of the Ng-Schauenburg Theorem for modular categories, which tells us that for any simple object \( X_a \), \( d_a \in \mathbb{Z} \left[ \zeta_N \right] \) where \( N = \text{ord} (T) \) [NS1].

One might wonder if this theorem holds in the premodular setting despite the appearance of the \( R \)-matrices. However, examination of the premodular category \( \mathcal{C} (sl(2), 8)_{ad} \) reveals that the Ng-Schauenburg Theorem fails, but that Conjecture 3.5 holds. Preliminary results indicate that more complicated combinations of the \( R \)-matrices may appear in higher indicators so more work is needed before the techniques of Ng and Schauenberg can be applied to Conjecture 3.5. However, this conjecture has been verified for premodular categories of rank \( < 5 \).

### 4. Rank 4 Premodular Categories

To classify all rank 4 premodular categories, we would need to determine the premodular datum \( (\tilde{S}, T, N_0, \ldots, N_n) \) in addition to the \( R \)- and \( F \)-matrices. However, Ocneanu Rigidity tells us that there are only finitely many braided fusion categories realizing a given fusion ring and so it suffices to understand only the premodular datum. When classifying modular categories, one has a full range of Galois techniques available in addition to the divisibility of dimensions and the universal grading group. However, in the premodular setting, all of these techniques fail. Indeed, examination of \( \mathcal{C} (sl(2), 8)_{ad} \) reveals that the universal grading group need not be isomorphic to \( \mathcal{C}^{pt} \), the full subcategory generated by the invertible objects. This category further illustrates that the Ng-Schauenburg
Theorem fails. If we instead consider $\mathcal{C}(\text{sl}(2),6)_{\text{ad}}$, then we see that (the square of) the dimensions of the simple objects need not divide the categorical dimension. Finally, the tensor category $\text{Fib} \times \text{Rep}(\mathbb{Z}_2)$ reveals that the Galois techniques fail in the premodular setting.

Given the failure of many of the techniques used in modular classification, what is left? To perform low rank premodular classification, people have, in the past, examined the double $\mathcal{Z} (\mathcal{C})$ as a module category [O1]. However, in the rank 4 case, this approach is infeasible due to the number of simple objects. To overcome these difficulties, we will make use of the equations governing the premodular datum as well as cyclotomic and number theoretic techniques; the minimal modularization developed by Bruguieres; and the 2nd Frobenius-Schur indicators.

Recalling our partition of premodular categories into symmetric, properly premodular, and modular, we will discuss each of these classes in turn. We begin with the symmetric case, which is readily dealt with using the classification due to [Deligne].

**Proposition 4.1.** If $\mathcal{C}$ is a rank 4 symmetric category, then it is Grothendieck equivalent to $\text{Rep}(G)$ where $G$ is $\mathbb{Z}_4$, $\mathbb{Z}_2 \times \mathbb{Z}_2$, $D_{10}$, or $\mathcal{A}_4$.

Continuing onto the well understood setting of modular categories. We recall that much of the classification has been completed in [RSW]. The omissions will be filled in and the classification completed in the following result.

**Proposition 4.2.** If $\mathcal{C}$ is a rank 4 modular category then it is Galois conjugate to a modular category from [RSW] or has $S$-matrix

$$\tilde{\mathcal{S}} = \begin{pmatrix} 1 & -1 & \tilde{\tau} & \tau \\ -1 & 1 & \tau & -\tilde{\tau} \\ \tilde{\tau} & -\tau & 1 & -1 \\ \tau & -\tilde{\tau} & -1 & -1 \end{pmatrix},$$

where $\tau = \frac{1+\sqrt{5}}{2}$ is the golden mean and $\tilde{\tau} = \frac{1-\sqrt{5}}{2}$ is its Galois conjugate.

**Proof.** By [RSW], the only case left to examine is when the Galois group is $((0,1)\quad (2,3))$ and $\mathcal{C}$ is not pseudo-unitary. To maintain a more coherent thought process, we will consider the case that $\mathcal{C}$ is modular and has Galois group $((0,1)\quad (2,3))$. Applying the standard Galois techniques present in [RSW] leads to

$$\tilde{\mathcal{S}} = \begin{pmatrix} 1 & d_1 & d_2 & d_3 \\ d_1 & \epsilon_0 & \epsilon_3 d_3 & \epsilon_0 \epsilon_3 d_2 \\ d_2 & \epsilon_3 d_3 & s_{23} & s_{22} \\ d_3 & \epsilon_0 \epsilon_3 d_2 & s_{22} & \epsilon_0 \epsilon_3 s_{22} \end{pmatrix}.$$ 

Since $\epsilon_0 = \pm 1$ we consider these two cases separately.

---

2The dimensions of the simple objects need not live in the cyclotomic extension of $\mathbb{Q}$ generated by the twists.

3The author would like to thank Eric Rowell for suggesting this approach.
Case 1: $\epsilon_0 = 1$.
Orthogonality of the first two columns of $\tilde{S}$ gives $d_1 = -\epsilon_3 d_2 d_3$. Applying our Galois element to this equation gives that $\epsilon_3 = -1$. Next, orthogonality of the last two columns gives us that $\tilde{s}_{23} \tilde{s}_{22} = -d_2 d_3$ and $\tilde{s}_{22} = -1$ or $\tilde{s}_{22} = d_2^2$. We now examine these two subcases separately.

Case 1.1: $s_{22} = d_2^2$
Applying the orthogonality of the first and the fourth columns of the $S$–matrix we find that $d_3 = \pm d_2$, we can apply the Verlinde formula and this relation to compute $N^k_{11} = d_3 - \frac{1}{d_3}$ and so $d_3 = \left(\frac{\sqrt{4 + \sqrt{n^2}}}{2}\right)^{\theta_1}$ for some $n \in \mathbb{N}$. Examining the remaining $N^k_{ij}$ we find that either $n = 0$ or $d_2 = d_3$. However, if $n = 0$, we have $d_a = \pm 1$ for all $a$. Since rank 4 pointed modular categories have been classified we may assume $d_2 = d_3$. Under this assumption the $S$–matrix takes the form

$$\tilde{S} = \begin{pmatrix} 1 & d_2 & d_3 & d_3 \\ d_2^2 & 1 & -d_3 & -d_3 \\ d_3 - d_3 & d_2^2 & -1 \\ d_3 - d_3 & -1 & d_2^2 \end{pmatrix}.$$ 

Applying the balancing relation– equation [2.12], and the Verlinde formula, we find

$$-1 = \tilde{s}_{23} = \left(\frac{n \pm \sqrt{4 + n^2}}{4d_2 \theta_1}\right)^{\theta_1}.$$ 

We now examine these two subcases separately.

Case 1.2: $s_{22} = -1$
In this case, we apply the Verlinde formula to compute $N^2_{11}$ and $N^3_{11}$ which leads to $d_2 = \frac{1}{2} \left(n \pm \sqrt{4 + n^2}\right)$ and $d_3 = \frac{1}{2} \left(m \pm \sqrt{4 + m^2}\right)$ for some $m, n \in \mathbb{N}$. The balancing equation for $\tilde{s}_{23}$ gives that $\theta_1 = \theta_2 \theta_3$ which then leads to

$$d_2 = \pm \sqrt{\frac{-1 + \theta_2 - \theta_2^2}{\theta_2}}, \quad d_3 = \pm \sqrt{\frac{-1 + \theta_3 - \theta_3^2}{\theta_3}}$$

by the balancing relation for $\tilde{s}_{22}$ and $\tilde{s}_{33}$. However, these results imply that $\theta_2$ and $\theta_3$ satisfy degree 4 integral polynomials and are roots of unity. Applying the inverse Euler (totient) phi function, we see that $\theta_2, \theta_3$ are $\pm i$ or primitive 5th roots of unity and so $d_2, d_3 \in \{\pm 1, \pm \tau, \pm \bar{\tau}\}$ where $\tau$ is the golden mean $\frac{1}{2} (1 + \sqrt{5})$ and $\bar{\tau}$ is its Galois conjugate. This leads to 48 $(\tilde{S}, T)$ combinations. Twelve of the $S$–matrices are distinct with half of them Galois conjugate to the other half. Of these remaining six, two can be removed by relabeling. Thus, we have the four $S$–matrices and their Galois conjugates:

$$\begin{pmatrix} 1 & -1 & \bar{\tau} & \tau \\ -1 & 1 & -\tau & \bar{\tau} \\ \bar{\tau} & -\tau & -1 & -1 \\ \tau & -\bar{\tau} & -1 & -1 \end{pmatrix}, \quad \begin{pmatrix} 1 & -1 & \tau & \bar{\tau} \\ -1 & -1 & -\tau & -\bar{\tau} \\ \bar{\tau} & -\tau & 1 & 1 \\ \tau & -\bar{\tau} & 1 & -1 \end{pmatrix}, \quad \begin{pmatrix} 1 & \tau^2 & \tau & \bar{\tau} \\ \tau^2 & 1 & -\tau & -\bar{\tau} \\ \bar{\tau} & -\tau & -1 & \tau^2 \\ \tau & -\bar{\tau} & \tau^2 & -1 \end{pmatrix}.$$
The second matrix can be discarded since there is no rank 2 modular category with $S$–matrix \( \left( \begin{array}{cc} 1 & -1 \\ -1 & 1 \end{array} \right) \). The last two matrices are pseudo-unitary and hence appear in [RSW] which leaves only the first $S$–matrix which corresponds to $\text{Fib} \boxtimes \text{Fib}$.

**Case 2:** $\epsilon_0 = -1$

By resolving the labelling ambiguity present between the 2 and 3 labels we can take $\epsilon_3 = 1$. There are now two subcases

**Case 2.1:** $|d_1| \geq 1$

Following the procedure of [RSW], we find that $d_1 = \frac{1}{2} \left( n \pm \sqrt{n^2 + 4} \right)$ and $\exists a, b \in \mathbb{Q}$ and $r, s \in \mathbb{Z}$ such that

\[
\begin{align*}
    r &= 2b + an, \quad s = bn - 2a, \\
    d_2 &= ad_1 + b, \quad d_3 = bd_1 - a, \\
    D^2 &= (1 + d_1^2)(1 + a^2 + b^2).
\end{align*}
\]

Additionally, their techniques lead to $|d_1|^4 \leq 1 + 5|d_1| + 8|d_1|^2 + 5|d_1|^3$. Coupling these results with $|d_1| \geq 1$ gives that $1 \leq |d_1| \leq \psi$, where $\psi$ is a root of $x^4 - 5x^3 - 8x^2 - 5x - 1$, and is approximately given by 6.38048. Thus $-7 < d_1 < 7$. We also find that

\[
    r^2 + s^2 \leq \left( n^2 + 4 \right) \frac{4|d_1|^3 + 5|d_1|^2 + 4|d_1| + 1}{|d_1|^2 (1 + |d_1|^2)}.
\]

Given a bound on $d_1$ we now have a bound on a sum of squares of integers and hence we can exhaust all possibilities. To do this we proceed in two subcases:

**Case 2.1.1:** $n > 0$

The fact that $d_1 = \frac{1}{2} \left( n + \sqrt{n^2 + 4} \right)$ implies $1 \leq n \leq 6$ and we have the case considered in [RSW]. From there it follows that $(n, r, s) = (1, -2, -1)$ or $(1, 2, 1)$ and $d_1 = \tau$, $d_3 = \pm \tau$ and $d_2 = \pm 1$. However, these lead to relabelings of the $S$–matrices from case 1.

**Case 2.1.2:** $n < 0$

Proceeding as in case 2.1.1, we find that there are 446 possible triples $(n, r, s)$ of which only 24 pass the integrality tests of [RSW]. Applying the Verlinde formula to determine the fusion rules in these cases, we find that all of these either violate the integrality or non-negativity of the fusion coefficients.

**Case 2.2:** $|d_1| < 1$

Applying our Galois element, we see that $\sigma(d_1) = -\frac{1}{d_1}$. Setting $\delta_i = \sigma(d_i)$, we find a category $\hat{C}$, which is Galois conjugate to $C$; whence if $\hat{C}$ does not exist, then neither does $C$. However, $|\delta_1| > 1$ and, since Galois conjugation preserves all categorical identities used in case 2.1, we see that we must have $\delta_3 = \delta_2 \delta_1$, $\delta_2 = \pm 1$ and $\delta_1 = \tau$. However, this is the same conclusion as in case 2.1.1. Ergo, $\hat{C}$ must be Galois conjugate to one of the case 2.1.1 results. Since these were conjugate

\[ \text{To see this, note that } N_{11}^1 = 0 \text{ by dimension count and the other fusion coefficients are determined by equation (2.9). However, these fusion coefficients violate the Verlinde formula.} \]
to the categories determined in [RSW], we can conclude that $C$ has an $S$–matrix Galois conjugate to one appearing in case 1.

Having dispensed with the symmetric and modular cases, we find that it is useful to stratify the properly premodular categories by duality and symmetric subcategory. It is known that that every properly premodular category has a symmetric subcategory. [Müger1] Since the rank has been fixed the possible symmetric subcategories can be completely determined.

**Proposition 4.3.** If $C$ is a rank 4 non-pointed properly premodular category, then there are four cases:

1. $\text{Rep}(S_3)$ is a symmetric subcategory and $C$ is self-dual.
2. $\text{Rep}(\mathbb{Z}_3)$ is a symmetric subcategory and $X_1^* = X_2$
3. $\text{Rep}(\mathbb{Z}_2)$ is a symmetric subcategory and $C$ is self-dual
4. $\text{Rep}(\mathbb{Z}_2)$ is a symmetric subcategory and $X_2^* = X_3$

**Proof.** We know from [Müger1] Corollary 2.16 and comments in the introduction that since $C$ is nonsymmetric and nonmodular, then it must have a nontrivial symmetric subcategory of rank 2 or 3. Rank 3 symmetric subcategories are known to be equivalent to $\text{Rep}(\mathbb{Z}_3)$ or $\text{Rep}(S_3)$ [O2]. Rank 2 proceeds similarly and leads to $\text{Rep}(\mathbb{Z}_2)$.

In the rank 3 case, we take $X_0$, $X_1$, and $X_2$ to be representatives of distinct simple isomorphism classes that generate the symmetric subcategory, while, in rank 2, we take $X_0$ and $X_1$ to be the representative generators. The result then follows immediately by standard representation theory.

Classification of the properly premodular categories now proceeds by cases. The categories with high rank symmetric subcategories are, perhaps not surprisingly, easier to deal with since more of the datum is predetermined. As such, we will proceed through $\text{Rep}(S_3)$ and $\text{Rep}(\mathbb{Z}_3)$ first and then discuss the $\text{Rep}(\mathbb{Z}_2)$ cases.

**Proposition 4.4.** There is no rank 4 non-pointed properly premodular category with $C' \cong \text{Rep}(S_3)$.

**Proof.** Applying the known representation theory of $S_3$, equation (2.9) and dimension counts, we find

$$N_1 = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad N_2 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 2 \end{pmatrix}, \quad N_3 = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 2 \\ 1 & 1 & 2 & M \end{pmatrix}.$$
Recall that $\tilde{s}_{ab} = d_a d_b$ for $0 \leq a, b \leq 2$ by [Müger1, Proposition 2.5]. Coupling this with equation (2.12), we find $\theta_1 = \theta_2 = 1$. Denoting $\theta_3$ by $\theta$, this gives

$$\tilde{S} = \begin{pmatrix} 1 & 1 & 2 & \frac{N + \sqrt{24 + M^2}}{2} \\ 1 & 1 & 2 & \frac{N - \sqrt{24 + M^2}}{2} \\ 2 & 2 & 4 & \frac{N + \sqrt{24 + M^2}}{2} \\ \frac{N + \sqrt{24 + M^2}}{2} & \frac{N - \sqrt{24 + M^2}}{2} & \frac{M + \sqrt{24 + M^2}}{2} & \frac{N + \sqrt{24 + M^2}}{2} \end{pmatrix}.$$ 

Since $\tilde{s}_{00}$ must satisfy the characteristic polynomial of $N_3$, we can deduce that $\theta$ must be a primitive root of unity satisfying a degree integral 3 polynomial. Employing the inverse Euler phi function, we find that $\theta = \pm 1$ and $M = 0$. Thus $d = \pm \sqrt{6}$. Having removed the free parameters from this datum, we are in a position to prove that such a category cannot exist. The M"uger center, $\text{Rep} (\mathcal{S}_3)$, constitutes a Tannakian subcategory of $\mathcal{C}$. By [NNW] and [DGNO, Remark 5.10], we can form the de-equivariantization, $\mathcal{C}_{\mathcal{S}_3}$, which is a braided $\mathcal{S}_3$-crossed fusion category. However, $\text{FPdim} (\mathcal{C}_{\mathcal{S}_3}) = \frac{1}{6} \text{FPdim} (\mathcal{C})$, $\dim (\mathcal{C}_{\mathcal{S}_3}) = \frac{1}{6} \dim (\mathcal{C}) = 2$, and $\text{FPdim} (\mathcal{C}_{\mathcal{S}_3}) = 2$ [DGNO]. Thus $\mathcal{C}_{\mathcal{S}_3}$ is weakly integral braided $\mathcal{S}_3$-crossed fusion category and we may apply [ENO Corollary 8.30] to deduce that $\mathcal{C}_{\mathcal{S}_3}$ is equivalent to $\text{Rep} (\mathbb{Z}_3)$ and hence pointed. Consequently, $\mathcal{C}$ is group-theoretical and in particular integral, contradicting $d = \pm \sqrt{6}$ [NNW][DGNO].

**Proposition 4.5.** If $\mathcal{C}$ is a non-pointed properly premodular category such that $\langle X_0, X_1, X_2 \rangle = \mathcal{C}' \cong \text{Rep} (\mathbb{Z}_3)$, then:

$$\tilde{S} = \begin{pmatrix} 1 & 1 & 3 & \frac{N + \sqrt{24 + M^2}}{2} \\ 1 & 1 & 3 & \frac{N - \sqrt{24 + M^2}}{2} \\ 3 & 3 & -3 & \frac{N + \sqrt{24 + M^2}}{2} \\ \frac{N + \sqrt{24 + M^2}}{2} & \frac{N - \sqrt{24 + M^2}}{2} & \frac{M + \sqrt{24 + M^2}}{2} & \frac{N + \sqrt{24 + M^2}}{2} \end{pmatrix}, T = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix},$$

$$N_1 = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad N_2 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad N_3 = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}.$$

and $\mathcal{C}$ is realized by $\mathcal{C} (\mathfrak{sl} (2), 6)_{ad}$.

**Proof.** Applying Proposition 4.3 we know that $\mathcal{C}$ is self-dual and so applying the representation theory of $\mathbb{Z}_3$ and equation (2.12), we find that the fusion matrices are determined up to $N_{33}^3$. Making use of equation (2.12), the fact that $\tilde{S} = \tilde{S}^T$, and the fact that in a properly premodular category some column of $\tilde{S}$ is a multiple of the first, one finds that

$$\tilde{S} = \begin{pmatrix} 1 & 1 & 1 & d_3 \\ 1 & 1 & 1 & d_3 \\ 1 & 1 & 1 & d_3 \\ d_3 & d_3 & d_3 & \frac{N_{33}^3 + \sqrt{24 + M_{33}^2}}{2} \end{pmatrix}, \quad T = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & d_3 \end{pmatrix}.$$

By dimension count, we see that $d_3 = \frac{1}{2} \left( N_{33}^3 \pm \sqrt{12 + N_{33}^2} \right)$. So it remains to determine $N_{33}^3$ and $\theta_3$. For notational brevity, we let $M = N_{33}^3$. Applying equation

\text{RANK 4 PREMODULAR CATEGORIES 17}
we find that
\[(\theta_3 - 1) \left( 18\theta_3 (\theta_3^2 + \theta_3 + 1) + \theta_3^2 M^4 + 3\theta_3(\theta_3 + 1)(\theta_3 + 2)M^2 + 18 \right)
= \pm (\theta_3 - 1) \left( 3\theta_3 (\theta_3^2 + \theta_3 + 2) \sqrt{M^2 + 12M} + \theta_3^2 \sqrt{M^2 + 12M^3} \right). \tag{4.1}\]
We first note that if $\theta_3 = 1$, then $C = C'$ contradicting the nonsymmetric assumption. Thus, $\theta_3$ satisfies a degree 6 integral polynomial. However, $\theta_3$ is a root of unity, so applying the inverse Euler phi function to determine a list of potential values for $\theta_3$. Combing the possible cases, one finds $N_{33}^3 \in \{0, 2\}$ and $\theta_3 \in \{-i, -1\}$. Applying Corollary 3 with $a = 3$, we find that only $N_{33}^3 = 2$ gives a rational integer. Evaluating equation (4.1) at $N_{33}^3 = 2$ reveals that $\theta = -1$ is the only solution. □

Having dispensed with the large symmetric subcategories, we need to consider the case that $\text{Rep} (\mathbb{Z}_2)$ appears as a symmetric subcategory. We first consider the non-self-dual case which can be dealt with by cyclotomic/number theoretic techniques.

**Proposition 4.6.** There is no rank 4 non-pointed properly premodular category such that $\langle X_0, X_1 \rangle = C' \cong \text{Rep} (\mathbb{Z}_2)$, and $X_2 = X_3$.

**Proof.** Given the standard representation theory of $\mathbb{Z}_2$ and the equation (2.9), we immediately obtain:

$$
N_1 = \begin{pmatrix}
0 & 1 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & N_{32}^1 & N_{33}^1 \\
0 & 0 & N_{33}^1 & N_{32}^1
\end{pmatrix}, \quad
N_2 = \begin{pmatrix}
0 & 0 & 1 & 0 \\
0 & 0 & N_{32}^1 & N_{33}^1 \\
0 & N_{33}^1 & N_{32}^1 & N_{33}^2 \\
1 & N_{32}^1 & N_{33}^2 & N_{33}^1
\end{pmatrix}, \quad
N_3 = \begin{pmatrix}
0 & 0 & 0 & 1 \\
0 & 0 & N_{33}^1 & N_{32}^1 \\
1 & N_{32}^1 & N_{33}^1 & N_{33}^2 \\
0 & N_{33}^1 & N_{32}^1 & N_{33}^2
\end{pmatrix}.
$$

Demanding that the fusion matrices mutually commute reveals that either $N_{32}^1$ or $N_{33}^1$ is 0 and the other is 1. Hence, the proof bifurcates into two cases.

**Case 1:** $N_{32}^1 = 1$ and $N_{33}^1 = 0$

Returning to the commutativity of the fusion matrices, we are reduced to one equation:

$$
2 = \left( N_{33}^2 \right)^2 - \left( N_{33}^3 \right)^2.
$$

However, such an equation lacks integer solutions which can be seen by reduction modulo 4.

**Case 2:** $N_{32}^1 = 0$ and $N_{33}^1 = 1$.

In this case the commutativity of the fusion matrices reveals that $N_{33}^2 = N_{33}^3$, which we will simply call $M$ for brevity. Applying the equation (2.12), and dimension count, we can determine the $S$–matrix to be

$$
\tilde{S} = \left( \begin{smallmatrix} 1 \\ M \pm \sqrt{1 + M^2} \\ M \pm \sqrt{1 + M^2} \end{smallmatrix} \right) \otimes \left( \begin{smallmatrix} 1 \\ 1 \\ 1 \end{smallmatrix} \right).
$$

If one proceeds without appealing to the Frobenius-Schur indicators then the Tambara-Yamagami with dimensions $1, 1, 1, \sqrt{3}$ appear. This can of course be excluded since such categories do not admit a braiding [Siehler].
Where $\theta := \theta_2 = \theta_3$ and $\theta_1 = 1$, which follows from the fact that some column of the $S$–matrix must be a multiple of the first. However, $\frac{2 \theta_2}{\theta_3}$ must satisfy the characteristic polynomial of $N_2$, which factors into two quadratics. Inserting this quotient into the factors, we find that $\theta$ must satisfy either a degree 4 or degree 8 polynomial over $\mathbb{Z}$. Since $\theta$ is a primitive root of unity we can apply the inverse Euler phi function to bound the degree of the minimal polynomial of $\theta$. Proceeding through all cases, we find that $M = 0$ and $\mathcal{C}$ is pointed. □

While this cyclotomic analysis has been quite fruitful, the remaining, properly premodular case proves to be resistant and so other approaches are necessary. We begin by recalling that every fusion category admits a (possibly trivial) grading. Since the category has small rank, the grading possibilities allow for further stratification of the problem.

**Proposition 4.7.** If $\mathcal{C}$ is a self-dual rank 4 non-pointed properly premodular category $\langle X_0, X_1 \rangle = \mathcal{C}' \cong \text{Rep}(\mathbb{Z}_2)$, then there are three cases.

1. $\mathcal{C}$ admits a universal $\mathbb{Z}_2$ grading
2. $\mathcal{C}$ does not admit a universal $\mathbb{Z}_2$ grading and $X_1 \otimes X_2 = X_2$
3. $\mathcal{C}$ does not admit a universal $\mathbb{Z}_2$ grading and $X_1 \otimes X_2 = X_3$

**Proof.** If $\mathcal{C}$ admits a nontrivial universal grading, then it must be by $\mathbb{Z}_2$. On the other hand, if $\mathcal{C}$ does not admit a universal grading, then $\mathcal{C}_{ad} = \mathcal{C}$ [DGNO]. Since $X_1$ generates $\mathcal{C}' \cong \text{Rep}(\mathbb{Z}_2)$, we can conclude that if $\mathcal{C}_{ad} = \mathcal{C}$ then either $X_1 \otimes X_2 = X_2$ or $X_1 \otimes X_2 = X_3$. □

With this proposition in hand we again proceed by cases. First, we consider with the relatively simple case: $\mathcal{C}$ admits a universal $\mathbb{Z}_2$ grading.

**Proposition 4.8.** Suppose $\mathcal{C}$ is a self-dual rank 4 non-pointed properly premodular category admitting a universal $\mathbb{Z}_2$ grading such that $\mathcal{C}' \cong \text{Rep}(\mathbb{Z}_2)$, then $\mathcal{C}$ is a Deligne product of the Fib with $\text{Rep}(\mathbb{Z}_2)$ or sVec.

**Proof.** Dimension count coupled with the representation theory of $\mathbb{Z}_2$ completely determines the fusion relations up to $N_{22}$. However, we can apply [O2] to conclude that $N_{22} \in \{0, 1\}$. $N_{22} = 0$ leaves a pointed category and so we must have $N_{22} = 1$, and $d := d_2 = d_3 = \frac{1+\sqrt{5}}{2}$. Applying equation (2.12) and the fact that a column of the $S$–matrix must be a multiple of the first we find that $\theta_1 = \pm 1$, $\theta := \theta_2 = \theta_1 \theta_3$, and

$$\tilde{S} = \begin{pmatrix} 1 & 1 & d & d \\ d & d & 1+\theta & 1+\theta \\ d & d & 1+\theta & 1+\theta \\ d & d & 1+\theta & 1+\theta \end{pmatrix} \quad T = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & \pm 1 & 0 & 0 \\ 0 & \pm \theta & 0 & 0 \\ 0 & 0 & \pm \theta & 0 \end{pmatrix}.$$ 

Since the normalized columns of the $S$–matrix are characters of the fusion ring, it must be that $\frac{1+\theta}{\theta^2}$ is a simultaneous root of the characteristic polynomials of $N_2$ and $N_3$. This gives the desired result. □
Finally, we come to the last two cases where \( C' \cong \text{Rep}(\mathbb{Z}_2) \) and there is no universal grading. These are by far the most complicated cases. To dispense with the first case we make use of the minimal modularization [Bruguieres].

**Proposition 4.9.** Suppose \( C \) is a self-dual, rank 4, non-pointed, properly premodular category such that \( C' \cong \text{Rep}(\mathbb{Z}_2) \), \( C \) does not admit a nontrivial universal grading, and \( X_1 \otimes X_2 = X_2 \), then

\[
\check{S} = \begin{pmatrix}
1 & 1 & 1 & 1 \\
2 & 2 & 2^{1+2\theta} & 2^{1+2\theta} \\
2 & 2 & 2^{1+2\theta} & 2^{1+2\theta}
\end{pmatrix}
\]

\[T = \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1
\end{pmatrix}
\]

\[N_1 = \begin{pmatrix}
0 & 1 & 0 & 0 \\
1 & 0 & 0 & 0 \\
1 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}
\]

\[N_2 = \begin{pmatrix}
0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
1 & 1 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}
\]

\[N_3 = \begin{pmatrix}
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
1 & 1 & 1 & 0
\end{pmatrix}
\]

and \( \theta \) is a primitive 5th root of unity. Such categories are realized by \( C = C(\text{so}(5), 10)_{ad} \).

**Proof.** The representation theory of \( \mathbb{Z}_2 \), dimension count, equation (2.9), and equation (2.12) give

\[N_1 = \begin{pmatrix}
0 & 1 & 0 & 0 \\
1 & 0 & 1 & 0 \\
1 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}
\]

\[N_2 = \begin{pmatrix}
0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
1 & 1 & N_{22}^{2} & N_{23}^{2} \\
0 & 0 & N_{33}^{2} & N_{33}^{2}
\end{pmatrix}
\]

\[N_3 = \begin{pmatrix}
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
1 & 1 & N_{33}^{2} & N_{33}^{2}
\end{pmatrix}
\]

\[\check{S} = \begin{pmatrix}
d_1 & d_2 & d_3 & d_4 \\
d_2 & 2^{1+2\theta} & N_{22}^{2}d_2 & N_{23}^{2}d_2 \\
d_3 & N_{23}^{2}d_2 & N_{23}^{2}d_2 & N_{23}^{2}d_2 \\
d_4 & N_{23}^{2}d_2 & N_{23}^{2}d_2 & N_{23}^{2}d_2
\end{pmatrix}
\]

\[\begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1
\end{pmatrix}
\]

Applying [Bruguieres] Proposition 4.2], we can deduce that \( C \) admits a modularization \( \check{C} \). We can now apply [Bruguieres] Proposition 4.4 and the equivalence between Bruguieres modularization and the de-equivariantization to deduce that \( \check{C} \) has rank 5 with simple objects \( I, Y_1, Y_2, Z_1, Z_2 \) such that \( Y_i^* \in \{Y_1, Y_2\} \) and \( Z_i^* \in \{Z_1, Z_2\} \). Utilizing Proposition [4.4] it is determined that \( \check{C} \) is pointed and hence \( d_2 = \pm 2 \) and \( d_3 = \pm 2 \). Dimension count then allows us to eliminate all fusion coefficients except for \( N_{33}^{2} \). Applying [NR, Theorem 4.2], we know that \( C \) is Grothendieck equivalent to \( \text{Rep}(D_4) \) and is group-theoretical. This gives \( d_2 = d_3 = 2 \), and determines the fusion coefficients. Applying equations (2.13) and (2.14), we find \( \theta_3 = \theta_2^{-1} \) and that \( \theta_2 \) is a primitive 5th root of unity. \( \square \)

The final case requires not only the minimal modularization of Bruguieres but also the second Frobenius-Schur indicators.

**Proposition 4.10.** Suppose \( C \) is a self-dual rank 4 non-pointed properly premodular category such that \( C' \cong \text{Rep}(\mathbb{Z}_2) \), \( C \) does not admit a nontrivial universal grading, and \( X_1 \otimes X_2 = X_3 \) then

\[
\check{S} = \begin{pmatrix}
1 & 1 & 1
\end{pmatrix} \otimes \begin{pmatrix}
1 \pm \sqrt{2}
\end{pmatrix}
\]

\[T = \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1
\end{pmatrix}
\]

\[N_2 = \begin{pmatrix}
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
1 & 1 & 1 & 1 \\
0 & 1 & 1 & 1
\end{pmatrix}
\]

\[N_3 = \begin{pmatrix}
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
0 & 1 & 1 & 1 \\
1 & 1 & 1 & 1
\end{pmatrix}
\]
such a category is realized by $\mathcal{C} = \mathcal{C} (\mathfrak{sl}(2), 8)_{ad}$ and its conjugates.

Proof. Applying dimension count, equation (2.9), and the usual representation theory for $\mathbb{Z}_2$, we can determine the fusion rules up to two parameters:

\[
N_1 = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \quad N_2 = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & N & M \\ 0 & 1 & N & M \end{pmatrix}, \quad N_3 = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & M & N \\ 1 & 0 & N & M \end{pmatrix}.
\]

Furthermore, we can deduce that $M, N \neq 0$ lest we reduce to the fusion rules of Proposition 4 or a pointed category. Next, we may use equation (2.12), dimension count, and that $\tilde{s}_{ij} = l \tilde{s}_{i0}$ for some $j$ and some $l \in \mathbb{C}^*$, to find the $S$- and $T$-matrices:

\[
\tilde{S} = \left( \frac{1}{N+M+\sqrt{4+(M+N)^2}} \right) \otimes \left( \begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array} \right), \quad T = \left( \begin{array}{cccc} 1 & 0 & 0 & 0 \\ 0 & \delta & 0 & 0 \\ 0 & 0 & 0 & \delta \theta \\ 0 & 0 & \theta & 0 \end{array} \right),
\]

where $\epsilon, \delta = \pm 1$. We treat $\delta = 1$ and $\delta = -1$ in separate cases.

Case 1: $\delta = 1$

Here we can apply [Bruguieres] to deduce that $\mathcal{C}$ is modularizable. Letting $H : \mathcal{C} \to \hat{\mathcal{C}}$ denote its minimal modularization then we have $X_2 \in M_{\mathcal{C}} X_3$ and so $H (X_2) \cong H (X_3)$. Furthermore, $\| \text{Stab}_{\mathcal{M}_\mathcal{C}} X \| = 1$ for all simple $X$ and thus, $\dim H (X_2) = \dim (X_2)$. Consequently, the trivial object in $\mathcal{C}$ as well as $H (X_2)$ account for $1 + d^2$ of the dimension of $\hat{\mathcal{C}}$. However, $\dim \hat{\mathcal{C}} = \frac{1}{2} \dim (\mathcal{C}) = 1 + d^2$ and so $\hat{\mathcal{C}}$ is a rank 2 modular category with simple objects $\mathbb{I}$ and $H (X_2)$. Such categories have been classified in [RSW] and are the Semion and the Fibonacci. In these situations, we find either that $\hat{\mathcal{C}}$ is pointed or that $M = N = 0$ and so we can exclude the case of $\delta = 1$.

Case 2: $\delta = -1$.

Applying the equations (2.13) and (2.14) to further reduces the solution space. Discarding any solutions where either $M$ or $N$ is 0 or $\mathcal{C}$ is symmetric leaves 7 possible families of solutions. One of these families contains a pythagorean triple with 1 which forces $N < 0$ and hence can be discarded. Two of the other families of solutions have $M$ and $N$ related by

\[
M = \frac{-N \theta^2 \pm \sqrt{\theta \left(1 + \theta^2\right) \left(1 - (1 + N^2) \theta + \theta^2\right)}}{\theta \left(1 + \theta (\theta - 1)\right)}.
\]

Since $\theta \neq 0$, this can be arranged into a monic integral degree 6 polynomial $\theta$. Since $\theta$ is a root of unity we can apply the inverse Euler phi function to find a possible list of values for $\theta$. Direct calculation reveals that none of these roots of unity can satisfy this polynomial in a manner consistent with $M, N > 0$.

The remaining four families can be reduced by resolving a labeling ambiguity.
to give
\[
\tilde{S} = \left( \frac{1}{N + \sqrt{1+N^2}} \right)^{N+\sqrt{1+N^2}} \otimes \left( \begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array} \right) \quad T = \left( \begin{array}{cccc} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{array} \right)
\]
\[
N_2 = \left( \begin{array}{cccc} 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & N & N \\ 1 & 0 & N & N \end{array} \right) \quad N_3 = \left( \begin{array}{cccc} 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & N & N \\ 1 & 0 & N & N \end{array} \right).
\]
Applying Corollary \ref{cor:3} to \(X_2\), we find that \(N \pm \frac{N^2-1}{\sqrt{N^2+1}} \in \mathbb{Z}\). Denoting this integer by \(L\) and simplifying we find
\[
4 = (N^2 + 1) \left( 3 + L^2 - 2LN \right)
\]
However, \(N^2 + 1 \neq 0\) and so, reducing modulo \(N^2 + 1\), we find that \(4 \equiv 0 \mod N^2 + 1\).
This only occurs for \(N \in \{-1, 0, 1\}\). Since \(N = 0\) leads to \(C\) being pointed and we know \(N \geq 0\), we can conclude that \(N = 1\). \(\square\)

The results of this section can be compiled to give the following theorem.

**Corollary 4.11.** If \(C\) is a non-pointed rank 4 premodular category, then exactly one of the following is true

1. \(C\) is symmetric and is Grothendieck equivalent to \(\text{Rep}(G)\) where \(G\) is \(\mathbb{Z}_4\), \(\mathbb{Z}_2 \times \mathbb{Z}_2\), \(D_{10}\), or \(\mathbb{A}_4\).
2. \(C\) is properly premodular and is Grothendieck equivalent to a Galois conjugate of one of the following: \(\text{C}(\text{sl}(2), 8)_{\text{ad}}\), \(\text{C}(\text{sl}(2), 6)_{\text{ad}}\), \(\text{C}(\text{so}(5), 10)_{\text{ad}}\), \(\text{Fib} \boxtimes \text{Rep}(\mathbb{Z}_2)\), or \(\text{Fib} \boxtimes \text{sVec}\).
3. \(C\) is modular and is Galois conjugate to a modular category from \[\text{RSW}\] or has \(S\)-matrix
\[
\begin{pmatrix}
1 & -1 & \tau & \bar{\tau} \\
-1 & 1 & -\tau & -\bar{\tau} \\
\tau & -\tau & 1 & -1 \\
\bar{\tau} & -\bar{\tau} & -1 & 1
\end{pmatrix},
\]
where \(\tau = \frac{1 + \sqrt{5}}{2}\) is the golden mean and \(\bar{\tau} = \frac{1 - \sqrt{5}}{2}\) is its Galois conjugate.
APPENDIX A. RANK 5 MODULAR CATEGORIES

Completion of the classification of rank 4 premodular categories required recourse to the minimal modularization of [Bruguières]. This necessitated understanding certain rank 5 modular categories. While a complete classification of rank 5 premodular categories is currently open, this appendix provides a partial result.

Take $\mathcal{C}$ to be a rank 5 modular category with $S$–matrix $\tilde{S}$, dimensions $d_a = \tilde{s}_{0a}$, and Galois group $\text{Gal}(\mathcal{C}) = \text{Gal}(\mathbb{Q}(\tilde{s}_{ab})/\mathbb{Q})$. We further assume that $\# \{d_i\} \leq 3$ and that $\mathcal{C}$ is non-integral. The non-integral assumption is not restrictive since [HR] proved that all rank 5 integral modular categories are pointed.

Recall, for future use, that [RSW, Theorem 2.10] tells us that $\text{Gal}(\mathcal{C})$ is an abelian subgroup of $\mathfrak{S}_5$ and if $\sigma \in \text{Gal}(\mathcal{C})$, then

$$\sigma(\tilde{s}_{bc}) = \frac{1}{d_{\sigma(0)}} \epsilon_{\sigma(c),\sigma} \tilde{s}_{\sigma(b),\sigma(c)},$$

$$\tilde{s}_{bc} = \epsilon_{\sigma(b),\sigma} \epsilon_{c,\sigma} \tilde{s}_{\sigma(b),\sigma^{-1}(c)},$$

for some $\epsilon_{a,\sigma} = \pm 1$.

Since $\mathcal{C}$ is non-integral, we know that 0 is moved by $\text{Gal}(\mathcal{C})$. This observation motivates the following lemma.

**Lemma A.1.** If $\mathcal{C}$ is modular and $\sigma \in \text{Gal}(\mathcal{C})$ with $\sigma(0) \neq 0$ then $\epsilon_{\sigma(0),\sigma} = 1$

**Proof.** Since $\tilde{s}_{00} = 1$ and $\sigma$ fixes $\mathbb{Q}$ pointwise, we have

$$1 = \sigma(1) = \sigma(\tilde{s}_{00}) = \frac{1}{d_{\sigma(0)}} \epsilon_{\sigma(0),\sigma} \tilde{s}_{\sigma(0),\sigma} = \epsilon_{\sigma(0),\sigma}.$$

□

**Lemma A.2.** If $\mathcal{C}$ is a non-integral rank 5 modular category with objects $X_i$ such that $X_0 = \mathbb{I}$, $\dim X_1 = \dim X_2$ and $\dim X_3 = \dim X_4$, then there does not exist $\sigma$ in $\text{Gal}(\mathcal{C})$ of order 2 or 3 moving 0.

**Proof.** Here we consider the order 2 and 3 cases separately starting with order 2. By relabeling and applying Lemma [A1] we may assume $\sigma(0) = 1$ and hence $\epsilon_{1,\sigma} = 1$. Then by relabeling, there are two cases $\sigma(2) = 2$ and $\sigma(3) = 2$.

**Case 1:** $\sigma(3) = 2$. First note that $\sigma(4) = 4$. Now, applying [RSW, Theorem 2.10], $d_1 = d_2$ and $d_3 = d_4$ we have

$$\sigma(\tilde{s}_{03}) = \frac{1}{d_1} \epsilon_{2,\sigma} d_2 = \epsilon_{2,\sigma}.$$
Since \( \sigma \) has order 2 we see that \( d_4 = d_3 = \tilde{s}_{03} = \epsilon_{2,\sigma} \). On the other hand we know that \( \tilde{s}_{03} = d_3 = d_4 = \tilde{s}_{04} \) and so we have
\[
\epsilon_{2,\sigma} = \sigma(\tilde{s}_{03}) = \sigma(\tilde{s}_{04}) = \frac{1}{d_1} \epsilon_{4,\sigma} d_4 \epsilon_{2,\sigma} - \frac{1}{d_1}.
\]
Rearranging we see that \( d_2 = d_1 = \epsilon_{4,\sigma} \) while \( d_4 = d_3 = \epsilon_{2,\sigma} \). This contradicts that \( C \) is non-integral.

**Case 2:** \( \sigma(2) = 2 \). Again applying [RSW] Theorem 2.10(3)], we have \( \sigma(\tilde{s}_{02}) = \epsilon_{2,\sigma} \) and consequently, \( d_1 = \tilde{s}_{02} = \epsilon_{2,\sigma} = \pm 1 \).

Furthermore, \( \sigma \) has order 2, \( \sigma(3) \neq 2 \), and \( \sigma(0) = 1 \) and so we must have \( \sigma = (0, 1) \) or \( \sigma = (0, 1)(3, 4) \).

In either case we can apply \( \tilde{S}\tilde{S}^\dagger = D^2 I \) and examine the \((0, 1)\) entry to find
\[
0 = \epsilon_{0,\sigma} \epsilon_{2,\sigma} + 2 \epsilon_{2,\sigma} + (\epsilon_{3,\sigma} + \epsilon_{4,\sigma}) d_3^2.
\]
Since \( \epsilon_{i,\sigma} = \pm 1 \) we must have \( d_3^2 \in \{ \pm \frac{1}{2}, \pm \frac{3}{2} \} \), but \( d_3 \) is a real algebraic integer and hence, we have a contradiction.

So, it remains to consider the case where \( \sigma \) has order 3. Again, we may assume that \( \sigma(0) = 1 \) and hence \( \epsilon_{1,\sigma} = 1 \). Therefore, \( \sigma = (013) \) or \( \sigma = (012) \). Proceeding case-by-case we have

**Case 3:** \( \sigma = (013) \). Applying [RSW] Theorem 2.10(3)], we find that \( d_2 = \pm 1 \), \( d_3 = \pm 1 \).

**Case 4:** \( \sigma = (012) \). When applying [RSW] Theorem 2.10(3)] and \( \left( \tilde{S}\tilde{S}^\dagger - D^2 I \right)_{01} = 0 \), we find that \( d_3 \) is not a real algebraic integer.

\( \square \)

Next we show that there cannot be a 5-cycle moving 0 in the Galois group.

**Lemma A.3.** If \( C \) is a non-integral rank 5 modular category with objects \( X_i \) such that \( X_0 = \mathbb{I} \), \( \dim X_1 = \dim X_2 \), \( \dim X_3 = \dim X_4 \), then \( \text{Gal}(C) \neq \mathbb{Z}_5 \).

**Proof.** By relabeling we may assume \( \sigma = (0 1 2 3 4), (0 1 3 2 4), \) or \( (0 1 3 4 2) \).

**Case 1:** \( \sigma = (0 1 2 3 4) \). Applying [RSW] Theorem 2.10(3)], gives \( d_1 = \tilde{s}_{01} = \epsilon_{2,\sigma} \) and \( \tilde{s}_{00} = \epsilon_{0,\sigma} \). Since the Galois group fixes \( \mathbb{Z}_5 \), we know \( \sigma(\tilde{s}_{02}) = \epsilon_{2,\sigma} \). Coupling this with [RSW] Theorem 2.10(3)] tells us that \( d_3 = \pm 1 \), contradicting that \( C \) is non-integral.

**Case 2:** \( \sigma = (0 1 3 2 4) \). Applying to \( \tilde{s}_{01} \) and \( \tilde{s}_{02} \) gives \( d_3 = \pm 1 \). Next applying \( \sigma \) to \( \tilde{s}_{03} \) and noting that the Galois group fixes \( \pm 1 \), we find \( d_1 = \pm 1 \), again contradicting that \( C \) is non-integral.

**Case 3:** \( \sigma = (0 1 3 4 2) \). Applying [RSW] Theorem 2.10(3)] to \( \tilde{s}_{03} \), we find \( d_3 = \pm 1 \). On the other hand, applying \( \sigma \) to \( \tilde{s}_{04} \) gives \( d_1 = \pm 1 \). Since \( d_1 = d_2 \) and \( d_3 = d_4 \) we have a contradiction.

\( \square \)

Having restricted the types of subgroups of \( \mathfrak{S}_5 \) that can appear as the Galois group of such a category gives the following partial classification.
Proposition A.4. If $\mathcal{C}$ is a rank 5 modular category with simple objects $X_i$ such that $X_0 = \mathbb{I}$, $\dim X_1 = \dim X_2$ and $\dim X_3 = \dim X_4$, then $\mathcal{C}$ is pointed.

Proof. First note that if $\mathcal{C}$ is integral then $\mathcal{C}$ is pointed by [HR]. So we may assume that $\mathcal{C}$ is non-integral and hence 0 is moved by the Galois group. Since the Galois group must be an abelian subgroup of $S_5$ moving zero, the only options up to relabeling are

| Isomorphism class | representative group |
|-------------------|----------------------|
| $\mathbb{Z}_2$    | $\langle (0, 1) \rangle$ |
| $\mathbb{Z}_2 \times \mathbb{Z}_2$ | $\langle (0, 1), (2, 3) \rangle$ |
| $\mathbb{Z}_2 \times \mathbb{Z}_2$ | $\langle (0, 1)(2, 3), (0, 2)(1, 3), (0, 3)(1, 2) \rangle$ |
| $\mathbb{Z}_4$    | $\langle (0, 1, 2, 3) \rangle$ |
| $\mathbb{Z}_6$    | $\langle (0, 1, 2), (3, 4) \rangle$ |
| $\mathbb{Z}_5$    | $\langle (0, 1, 2, 3, 4) \rangle$ |

Even after relabeling, each of these will contain an element of order 2, 3, or 5 moving zero. Applying the prior three lemmas give the desired result. □

Acknowledgements

I’d like to thank Eric Rowell for very useful discussions, guidance, and inspiration. I’d also like to thank Tobias Hagge, David Jordan, Richard Ng, and Zhenghan Wang for their enlightening discussions at Texas A&M and AIM.
