† Dedicated on 90-th Birthday to Sir Roger Penrose as a tribute to his ideas and achievements.

Abstract: We construct recently introduced palatial NC twistors by considering the pair of conjugated (Born-dual) twist-deformed $D = 4$ quantum inhomogeneous conformal Hopf algebras $U_θ(su(2, 2) \ltimes T^4)$ and $U_θ(su(2, 2) \ltimes \bar{T}^4)$, where $T^4$ describes complex twistor coordinates and $\bar{T}^4$ the conjugated dual twistor momenta. The palatial twistors are suitably chosen as the quantum-covariant modules (NC representations) of the introduced Born-dual Hopf algebras. Subsequently, we introduce the quantum deformations of $D = 4$ Heisenberg-conformal algebra (HCA) $su(2, 2) \ltimes H^4$ ($H^4 = \bar{T}^4 \ltimes_θ T^4$ is the Heisenberg algebra of twistorial oscillators) providing in twistorial framework the basic covariant quantum elementary system. The class of algebras describing deformation of HCA with dimensionfull deformation parameter, linked with Planck length $\lambda_p$, is called the twistorial DSR (TDSR) algebra, following the terminology of DSR algebra in space-time framework. We describe the examples of TDSR algebra linked with Palatial twistors which are introduced by the Drinfeld twist and the quantization map in $H^4$. We also introduce generalized quantum twistorial phase space by considering the Heisenberg double of Hopf algebra $U_θ(su(2, 2) \ltimes T^4)$.

Keywords: quantum deformations; quantum gravity; classical and quantum twistor geometry

1. Introduction

1.1. Towards Quantum Gravity

One can distinguish two basic levels in quantization procedure of physical models describing contemporary fundamental interactions:

(i) The first level can be called quantum-mechanical with canonically quantized phase space coordinates and possible presence of classical gravity only as a static background. On such a level, we find all familiar relativistic quantum field theories, e.g., QED and QCD (fields quantized, space-time geometry flat and Minkowskian).

(ii) The second level also has quantized gravity and noncommutative space-times (all fields, including gravity and space-time geometry are quantized).

Quantum gravity (QG) remains a subject of rather hypothetical models (see, e.g., [1–4]), however it is mostly agreed that QG effects require at ultra-short distances the replacement of classical Einsteinian space-time by quantum noncommutative space-time geometry (see [5]). The QG-generated noncommutativity corrections appear as proportional to the powers of Planck mass $m_p$ or inverse powers of Planck length $\lambda_p$.

$$\lambda_p = \frac{\hbar}{m_p c} = \sqrt{\frac{\hbar G}{c^3}}$$

where $c$ is the light velocity and $G$ is the gravitational Newton constant. The QG origin of Planck length can be seen from Formula (1), with simultaneous presence of $\hbar$ and $G$.

In order to study algebraically the QG modifications of the space-time geometry in Special Relativity, one can look at the $\lambda$-dependent deformations $U_λ(\mathbb{P}^{3,1})$ of the Poincaré
algebra $\mathcal{P}^{3,1} = o(3,1) \ltimes \mathcal{P}^{3,1}$, where $\mathcal{P}^{3,1}$ denotes the four-momenta sector and $\lambda$ describes an elementary length parameter which can be fixed $\lambda = \lambda_p$. Further, we consider the Minkowski space-time coordinates $x_\mu \in M^{3,1}$ together with covariantly acting Poincaré symmetry and introduce the semi-direct product algebra
\[ \mathbb{A} = \mathcal{P}^{3,1} \ltimes M^{3,1} \simeq o(3,1) \ltimes (\mathcal{P}^{3,1} \ltimes M^{3,1}) \]  
where $\mathcal{P}^{3,1} \ltimes M^{3,1}$ describes the relativistic phase space $\mathcal{P}^{3,1} = (M^{3,1}; \mathcal{P}^{3,1})$, which after the first quantization level is endowed with relativistic Heisenberg algebra structure. Such algebra $\mathbb{A}_\hbar$, also called Heisenberg–Lorentz algebra, can be further deformed into quantum algebra $U_\hbar (\mathbb{A}_\hbar)$, which, to describe quantum symmetry, should have Hopf algebra or Hopf-algebroid structure. We stress that only $U_\hbar (\mathbb{A}_\hbar)$ has the algebraic structure of Hopf algebroid [8–13].

Such class of deformations of algebra (2) provides so-called DSR (Doubly Special Relativity) algebra describing quantum space-times with covariantly acting quantum symmetry. We use the original name for DSR algebras [14–17], however some authors use the name DSR for “Deformed Special Relativity’, which has a vague informative content. The name “doubly” is due to the dependence on two parameters: $c$ (light velocity) and $\lambda_p$ (Planck length, or $m_p \sim (\hbar \lambda_p)^{-1}$). The first parameter, $c$, appears in the physical basis of the relativistic classical algebra $\mathbb{A}$ and the second parameter, $\lambda$, determines the QG-induced modification of the algebraic structure (2).

It was argued already in the 1930s [18] that QG models should at the basic level depend on three fundamental nonvanishing constants, $c$, $\hbar$ and $G$, where $G$ can be replaced by $\lambda_p$ or $m_p$ (see (1)); if the cosmological constant or de Sitter radius of the Universe is finite, it introduces additional geometric parameter. The variant of DSR algebra with additional de Sitter radius as additional geometric parameter was called Triply Special Relativity (TSR); see [19].

The model of quantum space-time symmetries, which was an inspiration for introducing DSR algebras, is provided by the $\kappa$-deformed Poincaré–Hopf algebra [20,21] with semi-direct product structure presented in [22] in so-called bicrossproduct basis.

Our aim is to describe some class of quantum-deformed twistors and provide the counterpart of DSR algebra in the noncommutative framework of quantum twistors. It should be recognized here that there are already several interesting papers dealing with quantum deformations of twistors and their geometries (see, e.g., [23–29]).

1.2. Elements of Twistor Theory

For more than half of a century, Roger Penrose and his collaborators (see, e.g., [23,30–32]) have promoted the idea that the space-time manifold is a secondary geometric construction, and primary geometric objects are twistors. In $D = 4$ flat space-time, twistors are introduced as four-dimensional complex conformal spinors $t_A \in T^4$, endowed with the $D = 4$ conformal-invariant pseudo-Hermitian $U(2,2)$ scalar product
\[ (\bar{t}, t) = \bar{t}_A \eta^{AB} t_B, \quad A, B = 1, 2, 3, 4 \]  
where $\bar{t}_A \in T^4$ are the complex-conjugated dual twistors and $\eta^{AB} = (1, 1, -1, -1)$. If we introduce twistors as the pair of $D = 4$ Weyl spinors ($\alpha = 1, 2$)
\[ t_A = (\pi_\alpha, \omega^\alpha) \]  
the alternative $U(2,2)$ frame should be used, with the metric
\[ \eta^{AB} = \begin{pmatrix} 0 & 1_2 \\ 1_2 & 0 \end{pmatrix}, \]
leading to the formula
\[ (\hat{I}, t) \equiv \hat{I}_A \eta^{AB} \hat{I}_B = \pi_\alpha \omega^\alpha + H.C. \] (6)

We recall that the points \( z_\mu \) of complex Minkowski space-time are specified in \( T^4 \) by two-dimensional planes with twistor coordinates, \((\pi_\alpha, \omega^\alpha)\), satisfying the Cartan–Penrose incidence relation
\[ \omega^\alpha = iz^{\bar{\beta}_\alpha} \pi_{\bar{\beta}_\alpha}, \quad z^{\bar{\beta}_\alpha} = \frac{1}{2} (\sigma^\mu)^{\bar{\beta}_\alpha} z_\mu. \] (7)

The quantum-mechanical twistors \( \hat{I}_A, \hat{\bar{I}}_A \) on first basic quantization level are provided by the oscillator-like canonical commutation relations (CCR) [23,30].
\[ [\hat{I}_A, \hat{I}_B] = i \hbar \eta_{AB} \] (8)
\[ [\hat{I}_A, \hat{\bar{I}}_B] = [\hat{\bar{I}}_A, \hat{I}_B] = 0. \] (9)

One can call \( \hat{I}_A \) the twistor coordinates and \( \hat{\bar{I}}_A \) the twistor momenta; they introduce the twistorial analog of the relativistic quantum-mechanical phase-space algebra for conformal-covariant twistorial models. We recall that one can obtain the twistor realization of \( D = 4 \) conformal algebra \( o(4, 2) \simeq su(2, 2) \) given by the bilinear products of Quantum-Mechanical (QM) twistors \( \hat{I}_A, \hat{\bar{I}}_A \) (see also Section 3.1).

The twistors \( \hat{I}_A \in T^4 \) satisfying the Cartan–Penrose incidence relations (7) provide the geometric alternative for the description by complex Minkowski space-time geometry. The real Minkowski coordinates \( x_\mu(z_\mu = x_\mu + iy_\mu) \) are obtained if the \( 2 \times 2 \) Hermitian matrix \( z^{\bar{\beta}_\alpha} \) is parameterized as follows
\[ z^{\bar{\beta}_\alpha} = \begin{pmatrix} x_0 + x_3 & x_1 + ix_2 \\ x_1 - ix_2 & x_0 - x_3 \end{pmatrix} = (z^{\bar{\beta}_\alpha})^s \] (10)

In such a case, one gets from (7) that \( (i, t) = 0 \), i.e., the real Minkowski coordinates have as twistor counterparts the null twistor planes (so-called \( a \)-planes), with vanishing norm (6).

For the discussion of QG effects, it is more appropriate and realistic to consider twistors corresponding to curved space-time. The simplest examples of nonflat space-times are the ones with constant curvature \( R \) or cosmological constant \( \Lambda = \pm \frac{1}{R^2} \), where \( \Lambda > 0 \) for de Sitter and \( \Lambda < 0 \) for anti-de Sitter geometries. In such a case, the standard quantization relations (8) and (9) for twistors should be modified, with respective deformation determined by the \( \Lambda \)-dependent antisymmetric constant second rank twistor \( I_{AB} \), called in twistor theory the infinity twistor (see, e.g., [30]). In the basis (4), it is given by the following formula (we choose further \( \Lambda > 0 \))
\[ I_{AB} = \begin{pmatrix} \frac{\Lambda}{6} \epsilon_{\alpha \beta} & 0 \\ 0 & \epsilon^{\alpha \beta} \end{pmatrix}, \quad I_{AB} = -I_{BA}. \] (11)

One can introduce in twistorial phase space \( (T^4, T^4) \) the deformation of Poisson structure described by the following complex-holomorphic \((2, 0)\) symplectic two-form [27]
\[ \Omega_2 = d(I_{AB} t^A dt^B) = I_{AB} dt^A \wedge dt^B = \frac{\Lambda}{6} d\pi_\alpha \wedge d\pi^\alpha + d\omega_\alpha \wedge d\omega^\alpha \] (12)
generated by the holomorphic \((1, 0)\) Liouville one-form \( \Omega_1 = I_{AB} t^A dt^B \), where \( \Omega_2 = d\Omega_1 \). In dual twistor space \( T^4 \), the complex-anti-holomorphic \((0, 2)\) symplectic two-form (we denote \( \hat{I}_A = t^A = \eta_{AB} \bar{I}^B \))
\[ \Omega_2 = d(T^{AB} \hat{I}_A d\hat{I}_B) = T^{AB} d\hat{I}_A \wedge d\hat{I}_B = \frac{\Lambda}{6} d\bar{\pi}_\alpha \wedge d\bar{\pi}^\alpha + d\bar{\omega}_\alpha \wedge d\bar{\omega}^\alpha \] (13)
is complex-conjugated to (12), which leads to the relation

\[ I^{AB} = \frac{1}{2} \epsilon^{ABCD} I_{CD} = \begin{pmatrix} \epsilon_{\mu\nu} & 0 \\ 0 & \epsilon^{\mu\nu} \end{pmatrix}. \]  

(14)

It appears that, within the framework of Hopf-algebraic quantum deformations of inhomogeneous conformal algebras \( su(2,2) \), one gets separately the deformations of twistors \( \hat{t}^A \in T^4 \) and \( \hat{\ell} \in \mathcal{T}^4 \), which lead to the quantum-mechanical (first level) quantization of symplectic structures (12) and (13).

The deformed twistors obtained by the quantization of symplectic Poisson structures (12)–(14) are called the palatial twistors [27]. After the quantization procedure, one gets the holomorphic and anti-holomorphic noncommutativity relations modifying (9) as follows (further, in many formulae, we put \( \hbar = c = 1 \)).

\[ [\hat{\ell}^A, \hat{\ell}^B] = \hbar I^{AB}, \quad [\hat{t}^A, \hat{\ell}_B] = \hbar I_{AB}. \]  

(15)

1.3. Twist Deformations: From Space-Time to Twistors

Let us recall the well-known twisting procedure (see, e.g., [33,34]) of the Poincaré algebra \( \mathcal{U}(o(3,1) \ltimes P^{3,1}) \) which is semi-dual to twisted Poincaré algebra \( \mathcal{U}(o(3,1) \ltimes M^{3,1}) \).

For these two basic relativistic algebras (in Minkowski space-time and four-momentum space), one introduces the following basic Abelian twists

\[ \hat{L} = \exp \left( i \frac{\lambda^2}{2} \theta_{\mu\nu} p_{\mu} \otimes p_{\nu} \right), \quad p_{\mu} \in P^{3,1} \]  

(16)

\[ \hat{F} = \exp \left( i \frac{1}{2\lambda^2} \theta_{\mu\nu} x^\mu \otimes x^\nu \right), \quad x^\mu \in M^{3,1} \]  

(17)

where \( \theta_{\mu\nu} = -\theta_{\nu\mu} \) are real and dimensionless; the dimensionfull deformation parameter \( \lambda \) representing an elementary length in QG applications may be chosen as Planck length \( \lambda_p \). If we insert the twists (16) and (17) into the formulae for twist-deformed Hopf algebra modules (see, e.g., [5,35]), we get the quantization maps

\[ \hat{x}^\mu = \hbar^{-1} (\downarrow 1)(x^\mu \otimes 1) \]  

\[ \hat{p}_\mu = \hbar^{-1} (\uparrow 1)(p_\mu \otimes 1) \]  

(18)

One obtains explicitly the well-known noncommutative \( \theta \)-deformed coordinates called also DFR (Doplicher, Fredenhagen, Roberts) quantum space-times [36,37], where standard parameters \( \theta_{\mu\nu}^{DSR} \) in DSR deformation are dimensionfull—\( \theta_{\mu\nu}^{DSR} = \lambda^2 \theta_{\mu\nu} \), with the dimensionality \( |\theta_{\mu\nu}^{DSR}| = L^2 \) and \( |\theta_{\mu\nu}| = L^0 \). The choice of \( \theta_{\mu\nu} \) is purely geometric, selects directions in space-time, which are being deformed. We obtain from (18)

\[ [\hat{x}^\mu, \hat{x}^\nu] = i\lambda^2 \theta_{\mu\nu}. \]  

(19)

For the noncommutative \( \theta \)-deformed four-momenta we get

\[ [\hat{p}_\mu, \hat{p}_\nu] = \frac{i}{\lambda^2} \theta_{\mu\nu}. \]  

(20)

If we wish to obtain both deformations (19) and (20) inside one algebraic structure, we observe that due to Jacobi identity the canonical relations \( [x_\mu, p_\nu] = i\hbar \delta_{\mu\nu} \) should be modified and both deformations (19) and (20) can be embedded together only in a Hopf algebroid (see, e.g., [8–11]).

The paper is organized as follows. In Section 2, we describe the pair of twisted inhomogeneous \( D = 4 \) conformal algebras \( isu(2,2) \equiv su(2,2) \ltimes T^4, isu(2,2) \equiv su(2,2) \ltimes T^4 \). Using Hopf-algebraic twisting, we derive the NC relations (15) for holomorphic (chiral) and anti-holomorphic (anti-chiral) palatial twistors as the twist-generated quantum deformations. If we twist the primitive coproducts of \( su(2,2) \) generators, we can show that
the twistorial NC phase space coordinates \((\hat{T}^4, \hat{\mathcal{H}}^4)\) are covariant as Hopf algebra module under the action of respective twist-deformed inhomogeneous \(su(2,2)\) algebras.

In Section 3, we introduce the new notion of twistorial DSR (TDSR) algebra, in particular as \(\Theta_{AB}\)-deformed twistorial \(D = 4\) Heisenberg-conformal algebra \(su(2,2) \ltimes H_{k4}^4\), where \(H_{k4}^4 = \mathcal{T}_4 \ltimes \mathcal{T}_4\) containing both sectors \(\mathcal{T}_4\), \(\mathcal{T}_4\) simultaneously \(\Theta\)-deformed. For such purpose, we use the quantization map which follows from the quantized versions of symplectic structures (12) and (13), and suitably modifies the Kronecker delta in the relation (8). We propose the twist quantization by a Drinfeld twist \(\tilde{F}\) (see also Section 3.1)), which is related with the twists (29) and (30) and only in the linear approximation in \(\lambda\) of the quantization map provides the palatial twistors. Further, we consider generalized twistorial quantum phase spaces defined by twisted Heisenberg doubles of \(isu(2,2)\) and \(isu(2,2)\) Hopf algebras. In such a framework, following Brain and Majid, the quantum deformation of twistor geometry considered in Section 1.2 can be obtained by cotwist quantization of inhomogeneous conformal quantum groups \(ISU(2,2)\) and \(\tilde{ISU}(2,2)\), which, respectively, are Hopf-dual to twist-deformed \(isu(2,2)\) and \(\tilde{isu}(2,2)\) quantum symmetry algebras.

In the concluding Section 4, we present an outlook, with directions for possible future research.

2. Twisted Inhomogeneous \(D = 4\) Conformal Algebras, Born Duality and Palatial Twistors

2.1. From Poincaré to Inhomogeneous Conformal Algebras

If we pass from the \(D = 4\) relativistic space-time description of the Universe to twistorial geometric framework, the \(D = 4\) Lorentz algebra \(o(3,1) \simeq SL(2;\mathbb{C}) \oplus SL(2;\mathbb{C})\), with the four-vectors \(x_{\mu}, p_{\nu}\) replaced by \(D = 4\) conformal algebra \(o(4,2) \simeq su(2,2)\) with fundamental translational degrees of freedom described by twistors \((\hat{t}_A, \hat{\mathcal{T}}_A) \in \mathcal{T}_4\) spanning the canonical twistorial phase space. In the space-time approach, the orbital part of Lorentz algebra generators \(M_{\mu\nu}\) can be realized in terms of \(D = 4\) relativistic phase space variables \((x_\mu \in M^{3,1}, p_\mu \in \mathcal{B}^{3,1})\) \((\mu, \nu = 0,1,2,3)\) as follows

\[
o(3,1) : \quad M_{\mu\nu} = \hat{x}_{\mu} \hat{p}_{\nu}. \tag{21}\]

where the Formula (21) is applicable only to the spinless systems; for the extension with spin in the context of quantum deformations, see, e.g., [13].

Using the twistorial canonical oscillator algebra (8) and (9), one can analogously express in terms of twistorial phase space coordinates \((\hat{t}_A, \hat{\mathcal{T}}_A)\), the conformal generators \(S_{\alpha\beta} \in su(2,2)\) \((A, B = 1,2,3,4)\) (Using the basis (4) the physical 15 generators of \(D = 4\) conformal algebra can be expressed by the following bilinear formulas (see also Section 3.1)).

\[
p_{\alpha\beta} = \pi_\alpha \pi_\beta \quad M_{\alpha\beta} = \pi_\alpha \omega_\beta \quad M_{\hat{\alpha}\hat{\beta}} = \pi_\alpha \pi_{\hat{\beta}}
D = \pi_\alpha \omega^a + H.C. \quad K_{\alpha\beta} = \omega_{\alpha} \omega_\beta
\]

\[
S_{AB} = \hat{t}_A \hat{t}_B - \frac{1}{4} (t, t) \eta_{AB} \quad \eta^{AB} S_{AB} = 0 \tag{22}\]

where \(S_{AB}\) are the \(4 \times 4\) pseudo-Hermitian complex matrix \(u(2,2)\) generators

\[
S_{AB}^* = \eta_{AC} S_{CD} \eta_{DB}. \tag{23}\]

One can introduce the pair of Poincaré groups \((P_3^{3,1} = O(3,1) \ltimes M^{3,1}, P_4^{3,1} = O(3,1) \ltimes p^{3,1})\), with \(M^{3,1}, p^{3,1}\) describing Minkowski coordinates and four-momenta, as two cosets related by the Fourier transform

\[
M^{3,1} = \frac{P_3^{3,1}}{o(3,1)} \ni \{ x_\mu \} \quad p^{3,1} = \frac{P_4^{3,1}}{o(3,1)} \ni \{ p_\mu \}. \tag{24}\]
The twistorial counterparts of relations (24) appear as follows

\[ T^4 = \frac{ISU(2,2)}{SU(2,2)} \quad T^4 = \frac{ISU(2,2)}{SU(2,2)} \]

(25)

where \( ISU(2,2) = SU(2,2) \ltimes T^4 \) and \( ISU(2,2) = SU(2,2) \ltimes T^4 \) describe the semi-dual pair of twistorial inhomogeneous \( D = 4 \) conformal groups. The twistorial counterparts of relations (24) appear as follows

\[ T \]

The coset (27) parameterizes complex 2-planes in \( T^4 \times SU(2,2) \) and \( T^4 \times SU(2,2) \). The complex Minkowski coordinates \( z^{\alpha\beta} \in CM(4) \) (see (10)) can be introduced as parameterizing the following complex Grassmanian

\[ M(4) = \frac{SU(2,2)}{S(U(2) \otimes U(2))} \]

(26)

The coset (27) parameterizes complex 2-planes in \( T^4 \) which are determined by non-parallel pairs of intersecting twistors \( t_A^i (i = 1, 2; A = 1, \ldots 4; (t^1, t^2) \neq 0) \) and satisfy the pair (7) of Cartan–Penrose incidence relations. The complex Minkowski coordinates \( z^{\alpha\beta} = \frac{i}{2} (\sigma^\alpha)_{\beta\gamma} z^{\gamma\delta} \) are expressed by the pair of intersecting twistor coordinates \( t_A^i = (\pi^i, \omega^{ij}) \) as follows

\[ z^{\alpha\beta} = -\frac{i}{\pi^{1a} \pi^{2b}} (\omega^{1a} \pi^{2b} - \omega^{2a} \pi^{1b}) \]

(28)

The primary aim of the Penrose program during the last fifty years was to encode any curved Einsteinian space-time structure in geometric twistorial framework; in particular, it was important to find the vocabulary permitting to translate any general relativity solution in space-time into the twistorial language. This goal was however achieved only partially, with modest hopes that the program of finding the twistor formulation of general relativity theory will be fully successful. However, in last decade, Roger Penrose became inspired by the idea that perhaps it is an easier task to construct the twistorial noncommutative version of quantum gravity. Such a view, conceptually attractive, however still faces the basic question of how the appropriate formulation of quantum gravity in the space-time picture would look. On the twistorial side, some first steps towards the construction of twistorial quantum gravity model were provided by Penrose (see also [29]).

2.2. Twist-Deformed Inhomogeneous Conformal Hopf Algebras and Holomorphic/Anti-Holomorphic Quantum Twistors

Our first task is to show how the relations (15) can be obtained in the framework of quantum deformations of inhomogeneous \( D = 4 \) conformal algebras, with the respective holomorphic twistor coordinates \( t_A \in T^4 \) or anti-holomorphic twistorial conformal momenta \( t_A \in T^4 \). For such a purpose, we consider the pair of semi-dual Hopf algebras \( \mathbb{H}_0 \equiv U(isu(2,2)) = U(su(2,2) \ltimes T^4) \) and \( \mathbb{H}_0 \equiv U(isu(2,2)) = U(su(2,2) \ltimes T^4) \), with Hermitian-conjugated generators in \( T^4 \) and \( T^4 \), but with the same twistorial realization of \( D = 4 \) conformal subalgebra \( su(2,2) \). Subsequently, one gets the holomorphic and anti-holomorphic palatial twistors if the Hopf algebras \( \mathbb{H}_0 \) and \( \mathbb{H}_0 \) are twisted, respectively by the following pair of twists,
\[ \mathcal{F} = \exp(-\frac{1}{2\lambda} \Theta_{AB} \hat{t}_A \wedge \hat{t}_B), \]  
(29) 

\[ \mathcal{F} = \exp(-\frac{1}{2\lambda} \Theta_{AB} \hat{t}_A \wedge \hat{t}_B^\dagger), \]  
(30) 

where further, in Section 3.1 we justify the same dependence of twists (29) and (30) from the elementary length parameter \( \lambda \).

In the general case, the antisymmetric numerical tensor \( \Theta_{AB} \) can be chosen as complex, but, in the case of Palatini twistor, because \( \Theta_{AB} = I_{AB} \), they are real. The pair of twists (29) and (30) are dual under the twistorial Born map

\[ \hat{t}_A \leftrightarrow \hat{t}_A^\dagger, \quad \Theta_{AB} \rightarrow \Theta_{AB} \]  
(31)

which, as the twistorial counterpart of the Born duality map \( x_\mu \leftrightarrow p_\mu \) [39,40], interchanges the twistorial momenta \( \hat{t}_A \) and the twistorial coordinates \( \hat{t}_A^\dagger \).

The conformal twists (29) and (30) deforming, respectively, \( isu(2,2) \) and \( isu(2,2) \) Hopf–Lie algebras are the twistorial counterpart of the Poincaré twists (16) and (17)—the second one employed quite often in the space-time approach (see [33,34]). Further, the pair of Formulae (18) has the following counterpart in twistorial description

\[ \hat{t}_A = m[\mathcal{F}^{-1}(\triangleright \otimes 1)(\hat{t}_A \otimes 1)] = (\mathcal{F}^{-1}_{(1)} \triangleright \hat{t}_A) \mathcal{F}^{-1}_{(2)} \]  
(32) 

\[ \hat{t}_A^\dagger = m[\mathcal{F}^{-1}(\triangleright \otimes 1)(\hat{t}_A^\dagger \otimes 1)] = (\mathcal{F}^{-1}_{(1)} \triangleright \hat{t}_A^\dagger) \mathcal{F}^{-1}_{(2)}. \]  
(33) 

The generators \( \hat{t}_A^\dagger \) describe the \( U_\mathcal{F}(isu(2,2)) \) Hopf algebra modules and \( \hat{t}_A^\dagger \) span the module of Hopf algebra \( U_\mathcal{F}(isu(2,2)) \). Using the Hopf-algebraic action consistent with relation (6)

\[ \hat{t}_A \triangleright \hat{t}_B = \eta_{AB} \quad \hat{t}_A \triangleright \hat{t}_B = -\eta_{AB} \]  
(34)

one gets the following explicit formulae for conformal quantum twistors

\[ U_\mathcal{F}(isu(2,2)) : \quad \hat{t}_A^\dagger = \hat{t}_A + \frac{1}{\lambda} \Theta_{A}^{\dagger} \hat{t}_B \]  
(35) 

\[ U_\mathcal{F}(isu(2,2)) : \quad \hat{t}_A = \hat{t}_A - \frac{1}{\lambda} \Theta_{A} \hat{t}_B. \]  
(36)

Using the Formula (32) for \( \hat{t}_A^\dagger \) and (33) for \( t_A \), one gets additionally

\[ \hat{t}_A = t_A = \hat{t}_A^\dagger. \]  
(37)

We obtain the following two algebras describing twist-deformed quantum twistorial phase space coordinates \( (\hat{t}_A^\dagger, \hat{t}_A) \) and \( (\hat{t}_A, \hat{t}_A^\dagger) \)

\[ [\hat{t}_A^\dagger, \hat{t}_B] = 2 \frac{\lambda}{A} \Theta_{AB} \quad [\hat{t}_A^\dagger, \hat{t}_B] = 0 \quad [\hat{t}_A^\dagger, \hat{t}_B^\dagger] = \eta_{AB} \]  
(38) 

\[ [\hat{t}_A, \hat{t}_B^\dagger] = 2 \frac{\lambda}{A} \Theta_{AB} \quad [\hat{t}_A, \hat{t}_B^\dagger] = 0 \quad [\hat{t}_A, \hat{t}_B] = \eta_{AB}. \]  
(39)

It should be stressed that the twistorial quantum phase space coordinates \( (\hat{t}_A^\dagger, \hat{t}_A) \) satisfy the following Hermitian-conjugated algebra

\[ \hat{t}_A = (\hat{t}_A^\dagger)^\dagger \quad \hat{t}_A^\dagger = (\hat{t}_A)^\dagger. \]  
(40)

The shifts described by Formulae (35) and (36) are the examples of the Bogolyubov transformation (see [41]) of twistorial oscillators satisfying the relations (8) and (9).
2.3. The Twisted Conformal Covariance of Quantum Twistors and Born Duality Map

The relations (39) and (38) are quantum-covariant under the action of the twisted inhomogeneous conformal Hopf algebras $\mathbb{H}_F = U_F(isu(2,2))$ and $\mathbb{H}_k = U_k(isu(2,2))$, respectively. In order to demonstrate such a property, one should calculate the twist-deformed coproducts using the familiar similarity maps

$$\Delta_F(\hat{g}) = \mathcal{F}^{-1} \circ \Delta_0(\hat{g}) \circ \mathcal{F}$$

$$\Delta_F(\hat{g}) = \mathcal{F}^{-1} \circ \Delta_0(\hat{g}) \circ \mathcal{F}$$

where $\Delta_0(\hat{g}) = \hat{g} \otimes 1 + 1 \otimes \hat{g}$ and the generators $S_{AB} \in su(2,2)$ can be represented in terms of twistor coordinates $(\hat{t}_A, \hat{\bar{t}}_A)$ (see (21)). From Formulae (29), (30), (41) and (42), one obtains that

$$\Delta_F(\hat{t}_A) = \Delta_0(\hat{t}_A) \quad \Delta_F(\hat{\bar{t}}_A) = \Delta_0(\hat{\bar{t}}_A)$$

and

$$\Delta_F(\hat{S}_{AB}) = \Delta_0(\hat{S}_{AB}) + \lambda^{-1}(\Theta_B^D t_A \otimes i_D + \Theta_C^D t_C \otimes i_A)$$

$$\Delta_F(\hat{S}_{AB}) = \Delta_0(\hat{S}_{AB}) + \lambda^{-1}(\Theta_B^D t_A \otimes i_D + \Theta_C^D t_C \otimes i_A)$$

Due to the modification using (44) and (45) of the primitive coproducts of $S_{AB}$, one can show that

$$\mathbb{H}_F : \hat{g} \triangleright ([\hat{t}^F_A, \hat{t}^F_B] - \frac{2}{\lambda} \Theta_{AB}) = 0$$

$$\mathbb{H}_F : \hat{g} \triangleright ([\hat{t}^F_A, \hat{t}^F_B] - \frac{2}{\lambda} \Theta_{AB}) = 0$$

where we use the standard Hopf-algebraic formula defining the action $\triangleright$ of generators $\hat{h} \in \mathbb{H}$ on the products $\hat{a} \cdot \hat{b}$ ($\hat{a}, \hat{b} \in \mathcal{H}$)

$$\hat{h} \triangleright (\hat{a} \cdot \hat{b}) = (h(1) \triangleright \hat{a})(h(2) \triangleright \hat{b}).$$

where $\mathcal{H}$ is the $\mathbb{H}$-module algebra. We recall that, in the case of noncommutative $\theta_{\mu\nu}$-deformed quantum space-times and quantum four-momenta (see (19) and (20)), one gets analogously in coproducts $\Delta_F(M_{\mu\nu})$ and $\Delta_F(M_{\mu\nu})$ the additional terms which are linear in $\theta_{\mu\nu}$ and bilinear in four-momenta (for twist (16)) or bilinear in space-time coordinates (for twist (17)); these terms are needed for the twisted quantum Poincaré invariance of the algebraic relations (19) and (20) (see also [33]).

For coordinate and momenta twistors, one can consider the quantum covariance under two different inhomogeneous twisted conformal Hopf algebras $U_F(isu(2,2))$ and $U_k(isu(2,2))$, but they can be mapped into each other if we supplement the twistorial Born map (31) with the following exchange relation ($\Theta_{AB}$ in the general case are complex, but it should be observed that $\theta_{\mu\nu}$ in both Formulae (19) and (20) is real and not changing under the map (49)).

$$\Theta_{AB} \leftrightarrow \Theta_{BA}$$

The superposition of maps (31) and (49) leads to the following Born substitution rule of the twist factors (29) and (30)

$$\mathcal{F} \leftrightarrow \mathcal{F}$$

The relations (49) and (50) describe the Born partial duality (semi-duality) of inhomogeneous conformal Hopf-algebras $U_F(isu(2,2))$ and $U_k(isu(2,2))$ (see, e.g., [42–44]) with interchanged subalgebras of twistorial momenta and coordinates.

3. Twistorial DSR Algebra as Deformed Smashed Product of $su(2,2)$ and Twistorial Quantum Phase Space

3.1. Twistorial DSR (TDSR) Algebra

During 2000–2001, the notion of Double Special Relativity (DSR) was proposed, with the postulate that the geometry of special relativity in the presence of QG corrections is
modified by quantum corrections, with Planck mass or Planck length playing the role of mass-like deformation parameter. In fact, in Snyder model \[45\], introducing first in the literature NC quantum space-time coordinates \( \hat{x}_\mu \) by means of the relation

\[
[x_\mu, x_\nu] = g_{\mu\nu} \quad [\hat{x}] = L^2
\]

one usually assumes that \( g = \beta^2 \) (where \( \beta \) is a dimensionless constant) and one can consider Snyder model as the first historical example of DSR model. In the Hopf-algebraic framework of quantum groups, the general DSR algebra can be described as quantum algebra \( \mathcal{U}_A(\mathcal{H}_{DSR}) \), where \( \mathcal{H}_{DSR} \) is given by the Formula (2).

If we wish to introduce the twistorial counterpart of DSR theory, described by the corresponding class of twistorial DSR algebras, one should replace the algebra \( \mathcal{H}_{DSR} \) (see (2)) by the algebra \( \mathcal{H}_{TDSR} \)

\[
\mathcal{H}_{TDSR} = \bar{isu}(2,2) \ltimes T^4 \simeq isu(2,2) \ltimes T^4 \simeq su(2,2) \ltimes H_A^4
\]

where \( H_A^4 = T^4 \ltimes h \) denotes the quantum twistorial phase space, described by the twistorial oscillators algebra (see (8) and (9)). Subsequently, one can introduce the twistorial DSR (TDSR) algebra as described by the following quantum deformations:

\[
\mathcal{U}_A(\mathcal{H}_{TDSR}) \equiv \mathcal{U}_A(su(2,2) \ltimes h) H_A^4
\]

In Formula (53), we use the particular case of semi-direct product, called smash product (see, e.g., \[46,47\]) of the Hopf algebra \( \bar{H} \) and its module algebra \( A \)

\[
\mathcal{H} = \bar{H} \ltimes A.
\]

If \( h, h' \in \bar{H} \) and \( a, b \in A \), the multiplication rule in \( \mathcal{H} \) is described by the following formula

\[
(h \otimes a) \cdot (h' \otimes b) = h \cdot h'_{(1)} \otimes (a \circ h'_{(2)}) b
\]

which uses as input the coalgebraic sector in \( \bar{H} \).

One can propose two ways of constructing TDSR algebra (53), in analogy with the two ways of describing the relativistic quantum NC phase space in Snyder model (see \[48–50\]):

(1) by proposing the quantum twistorial map as given by Formulae (35) and (36) (further in this section we link such a map with a cochain twist quantization);

(2) by calculating for the quantum Hopf algebras \( \mathcal{U}_A(isu(2,2)) \) and \( \mathcal{U}_A(ish(2,2)) \) the Heisenberg double construction, which provides the generalized twistorial quantum phase space spanned by the quantum symmetry generators and the dual conformal quantum matrix group coordinates (for \( \kappa \)-deformed Poincaré–Heisenberg double see \[11,51\]; for \( \theta_{L\mu} \)-deformed Poincaré–Heisenberg double, see \[52,53\]).

3.2. De Sitter Twistors and Length/Mass Dimensionalities

In order to introduce into the twistor algebra in (8) and (9) the dimensionfull parameters, one can use the twistorial realization of conformal algebra generators \( (P_\mu, M_{(a\beta)}, M_{(a\dot{\beta})}, K_\mu, D) \), where

\[
[P_\mu] = L^{-1} \quad [M_{(a\beta)}] = [M_{(a\dot{\beta})}] = [D] = L^0, \quad [K_\mu] = L
\]

describe the length dimensionalities \( [L] = [M]^{-1} \) ([M] describes the mass dimensionality). Recalling twistorial realization of conformal algebra

\[
P_{a\dot{\beta}} = \pi_a \pi_{\dot{\beta}} \quad \quad M_{(a\beta)} = (M_{(a\dot{\beta})})^\dagger = \pi_{(a\omega_{\beta})}^\dagger \\
D = \pi_a \omega^{\alpha} + H.C. \quad \quad K_{a\dot{\beta}} = \omega_{a\alpha} \alpha_{\dot{\beta}}
\]
we can easily deduce that the length dimensions of Weyl spinors \( (\pi_\alpha, \omega_\alpha) \), \( (\bar{\pi}_\bar{\alpha}, \bar{\omega}_\bar{\alpha}) \) (see (4)) are the following

\[
[\pi_\alpha] = [\pi_\bar{\alpha}] = L^{-\frac{1}{2}} \quad [\omega_\alpha] = [\omega_\bar{\alpha}] = L^{\frac{1}{2}}
\]  

(59)

In particular, one can introduce the rescaled dimensionless \([u] = [\bar{u}] = L^0\) twistor components as follows

\[
u_A = \left( \frac{\lambda^\frac{1}{2} \pi_\alpha}{\lambda^{-\frac{1}{2}} \omega_\alpha} \right) \quad \bar{u}_A = \left( \frac{\lambda^\frac{1}{2} \bar{\pi}_\bar{\alpha}}{\lambda^{-\frac{1}{2}} \bar{\omega}_\bar{\alpha}} \right)
\]  

(60)

where \( \lambda \) is the fundamental length parameter. Generalizing the particular choice in (11) and (14) for palatial twistors to the antisymmetric tensorial matrix \( \Theta_{AB} \)

\[
\Theta_{AB} = \begin{pmatrix}
\theta_{\alpha\gamma} & \theta_{\alpha\delta}
\theta_{\bar{\beta}\bar{\gamma}} & \theta_{\bar{\beta}\bar{\delta}}
\end{pmatrix}
\]  

(61)

we postulate the following dimensionalities

\[
[\theta_{\alpha\gamma}] = L^2 \quad [\theta_{\alpha\delta}] = [\theta_{\bar{\beta}\bar{\gamma}}] = L \quad [\theta_{\bar{\beta}\bar{\delta}}] = L^0.
\]  

(62)

consistent with the assignment \( \Theta_{AB} = I_{AB} \).

Using (59) and (29)–(30), one obtains (recall the \([\lambda] = L\) that the expression

\[
f \equiv -2i\lambda \ln F = \Theta_{AB}^I A \wedge B = \theta_{\alpha\gamma} \pi^\alpha \wedge \pi^\gamma + \theta_{\alpha\delta} \pi^\alpha \wedge \Theta^{\delta\gamma} + \theta_{\bar{\beta}\bar{\gamma}} \bar{\omega}^\bar{\gamma} \wedge \pi^\bar{\gamma} + \theta_{\bar{\beta}\bar{\delta}} \bar{\omega}^\bar{\delta} \wedge \Theta^{\bar{\gamma}\bar{\delta}} = \lambda \Theta_{AB}^{(0)} u^A \wedge u^B
\]  

(63)

where \( \theta_{\alpha\gamma} = \lambda^2 \theta_{\alpha\gamma}^{(0)} \), \( \theta_{\alpha\delta} = \lambda \theta_{\alpha\delta}^{(0)} \), \( \theta_{\bar{\beta}\bar{\gamma}} = \theta_{\bar{\beta}\bar{\delta}}^{(0)} \) and \( \Theta_{AB}^{(0)} \) is dimensionless. It follows that \([f] = L\); similarly, one gets \([\bar{f}] = L\).

Due to these numerical values of dimensionalities in front of the exponent (63) in Formulae (29) and (30) the numerical factor \( \lambda^{-1} \) appears. It should be observed that, contrary to the case of space-time twists (16) and (17), in both twistorial twists (29) and (30), the scaling normalization factor is the same.

3.3. Twist Deformation of Twistors by Drinfeld Twist

One can construct the Drinfeld twist (see, e.g., \([38,54,55]\)) by multiplication of two-cocycle twists (29) and (30) in various ways, related by BCH-type formulas. Such twist can be used for twist quantization of the Heisenberg-conformal algebra (52), which becomes a quasi-bialgebroid described by the smash product of the conformal \( su(2,2) \) and canonical twistorial Heisenberg algebra as the \( su(2,2) \) module.

We consider the following cochain twist (see, e.g., \([34]\); \( \lambda \sim \frac{1}{m_p} \) is real).

\[
\mathbb{F} = \exp \left[ \frac{1}{2\lambda} (\Theta_{AB}^I A \wedge B + \Theta_{AB}^{I\bar{A}} A \wedge \bar{B}) \right]
\]  

(64)

In Formula (64), the exponential factor is dimensionless. Because \( \mathbb{F} \) does not satisfy the two-cocycle condition, the resulting twisted coproducts are not coassociative and the twist quantization will generate the quasi-bialgebroid structure.

One gets the twist-deformed quantum twistor variables \( \xi_R = (\hat{I}_A, \hat{I}_A) (R = 1 \cdots 8) \) as describing the twist quantization of Hopf algebra module

\[
\xi_{\mathbb{F}^R} = m(\mathbb{F}^{-1} \circ (\triangleright \otimes 1) \circ (\xi_R \otimes 1)).
\]  

(65)

If in (65), we insert (34) and (64), then calculate the contribution generated by the linear \( \lambda \)-term in \( f = \ln \mathbb{F} \), we get
\[ \hat{P}^i_A = \hat{I}_A + \lambda^{-1} \hat{\Theta}^i_A \hat{I}_B + o(\lambda^{-2}) \]  
\[ \hat{P}^i_B = \hat{I}_A - \lambda^{-1} \hat{\Theta}^i_A \hat{I}_B + o(\lambda^{-2}) \]  

(66)  

(67)

i.e., the linear term in the \( \lambda^{-1} \) power expression gives the quantization maps analogous to (35) and (36). Taking only the linear term into consideration, we obtain the following modification of twistorial CCR (see (8) and (9))

\[ [\hat{P}^i_A, \hat{P}^j_B] = (\eta_{AB} - 4\lambda^{-2} \hat{\Theta}^i_A \hat{\Theta}^j_B) \]  
\[ [\hat{P}^i_A, \hat{P}^j_B] = 2\lambda^{-1} \hat{\Theta}^i_A \hat{\Theta}^j_B \]  
\[ [\hat{P}^i_A, \hat{P}^j_B] = 2\lambda^{-1} \hat{\Theta}^i_B \hat{\Theta}^j_A. \]  

(68)  

(69)

The relations (66)–(69) without higher order terms in \( \lambda^{-1} \) can be treated as describing the quantization map for \( \Theta_{AB} \)-deformed twistorial Heisenberg algebra.

The canonical conformal covariance relations for coordinate and momentum twistors \((A, B = 1 \ldots 4; \hat{S}_{AB} \in su(2, 2))\)

\[ [\hat{S}_{AB}, \hat{I}_C] = \eta_{BC} \hat{I}_A \]  
\[ [\hat{S}_{AB}, \hat{I}_C] = -\eta_{AC} \hat{I}_B \]  

(70)  

(71)

after twisting by \( \mathbb{F} \) do not remain valid. We arrive at higher order terms in Formulae (66) and (67) and in (70) and (71) additional terms which contain, besides the \( su(2, 2) \) generators \( S_{AB} \) (see (22)), the bilinear products \( \hat{I}_A \hat{I}_B, \hat{I}_A \hat{I}_B, \) which together form the set of generators of \( Sp(8; R) \) algebra, which is realized linearly on the eight-dimensional real twistor space \( \rho_R = (\hat{I}_A + \hat{I}_A, i(\hat{I}_A - \hat{I}_A)). \) The algebra \( Sp(8; R) \) is known as providing the generalization of \( D = 4 \) conformal symmetries in the presence of tensorial central charges \( [56], \) and it leads to numerous applications, e.g., in the Vasiliev higher spin algebras \([57,58]\). One can conclude therefore that the twist (64), which simultaneously deforms both the twistorial coordinates and momenta, could be better adjusted to the twist quantization of inhomogeneous generalized conformal algebra \( isp(8; R) = R^8 \times Sp(8; R). \)

We recall that, for the algebra (52) and its \( \mathbb{F} \)-twisted quantum version, the coalgebraic sector can be defined only in the framework of quasi-bialgebroids (quasi-Hopf algebroids) \([8-13,59]\).

3.4. Heisenberg Doubles and Generalized Twistorial Quantum Phase Space

It can be shown that, in the \( D = 4 \) space-time framework, both \((4 + 4)\)-dimensional quantum phase space as well as the \((10 + 10)\)-dimensional one which also contains the Lorentz sector can be described as the Heisenberg doubles, providing various generalizations and extensions of Heisenberg algebra.

The Heisenberg double is a special example of the smash product (54), when \( \mathbb{A} \) is identified with the dual Hopf algebra \( \mathbb{H}^* \). In such a case, the nondegenerate bilinear Hopf pairing \( \langle \cdot, \cdot \rangle: \mathbb{A} \otimes \mathbb{A} \rightarrow \mathbb{C} \) between two Hopf algebra \( \mathbb{H} \) and \( \mathbb{H}^* \) is used, with the following action \( \mathbb{H} \triangleright \mathbb{H}^* \)

\[ h \triangleright a = a(1) < h, a(2) >. \]  

(72)

Subsequently, one can write

\[ h \triangleright (ab) = a(1) < h(1), a(2) > b(1) < h(2), b(2) > = (h(1) \triangleright a)(h(2) \triangleright b) \]  

(73)

in accordance with the action (48) on the Hopf algebra module. One can derive in \( \mathbb{H} \) the cross relations between the algebraic sectors of \( \mathbb{H} \) and \( \mathbb{H}^* \) \((h \equiv h \otimes 1, a \equiv 1 \otimes a)\)

\[ h \cdot a = a(1) < h(1), a(2) > h(2) \]  

(74)

which completes the multiplication table in \( \mathbb{H} \otimes \mathbb{H}^* \).

In applications of the Heisenberg double \( \mathbb{H} \ltimes \mathbb{H}^* \) to physical models, the Hopf-algebra \( \mathbb{H} \) usually describes the generalized quantum momenta, while the dual Hopf algebra \( \mathbb{H}^* \)
provides the sector of generalized quantum positions. In the four-dimensional space-time approach, one obtains the generalized \((10 + 10)\)-dimensional quantum phase space expressed as the Heisenberg double \( \mathcal{H}^{(P)} \) (\( \mathcal{H} = \mathcal{U}(\mathcal{G}) \)) denotes the enveloping Hopf–Lie algebra and \( \mathcal{H}^* = \mathcal{C}(\mathcal{G}) \) is the Hopf algebra of functions on the Lie group manifold \( \mathcal{G} \):

\[
\mathcal{H}^{(P)} = \mathcal{U}(i\hat{\delta}(3,1)) \times \mathcal{C}(IO(3,1))
\]

where \( i\hat{\delta}(3,1) \) describes Poincaré algebra and \( IO(3,1) \) the dual Poincaré group. In the quantum case, e.g., in applications to QG, both Hopf algebras in (75) can be quantum-deformed in a way preserving the Hopf-algebraic duality property, e.g., by twisting or \( \kappa \)-deformation [11,51,52].

In the twistor approach, one can choose as the generalized twistorial quantum phase space the following Heisenberg double

\[
\mathcal{H}^{(T)} = \mathcal{U}_A(isu(2,2)) \times \mathcal{C}_A(ISU(2,2))
\]

where the Planck length plays the role of dimensionful deformation parameter. In particular, one can consider in (76) the twist deformations with twists \( F, \bar{F} \) (see (29) and (30)).

If we observe that the twistors \( \hat{t}_A, \hat{\bar{t}}_A \) as well as the twists (29) and (30) are related by the Born map (see (31)), we obtain the following table of four Hopf algebras, describing possible twist-deformed inhomogeneous \( D = 4 \) quantum conformal symmetries and \( D = 4 \) inhomogeneous quantum conformal groups

\[
\begin{align*}
\mathcal{U}_A(isu(2,2)) & \overset{\text{Hopf duality}}{\rightleftharpoons} \mathcal{C}_A(ISU(2,2)) \\
\text{Born } \dagger \text{ duality} & \text{Born } \dagger \text{ duality}
\end{align*}
\]

(77)

By Hopf duality, the twist quantization of the algebra \( isu(2,2) \) (\( \bar{isu}(2,2) \)) is mapped into the cotwist quantization of the group \( ISU(2,2) \) (\( \bar{ISU}(2,2) \)) with the following properties of algebraic and coalgebraic sectors

\[
\begin{align*}
\text{Twist quantization} & \quad \overset{\text{Hopf duality}}{\rightleftharpoons} \quad \text{cotwist quantization} \\
\text{multiplication in algebra not changed, coproducts modified} & \quad \overset{\text{Hopf duality}}{\rightleftharpoons} \quad \text{multiplication in algebra modified, coproducts unchanged}
\end{align*}
\]

(78)

In \( D = 4 \), the most general \((23 + 23)\)-dimensional twistorial DSR (TDSR) algebra can be described by the deformed Heisenberg double (76) with \((4 + 4)\) NC degrees of freedom in \( T^4 \oplus \bar{T}^4 \) and \((15 + 15)\)-dimensional conformal sector as the subalgebra described by the \( su(2,2) \) Heisenberg double.

If the Hopf algebras \( \mathcal{U}(isu(2,2)), \mathcal{U}(\bar{isu}(2,2)) \) are twist-deformed, the cotwist-deformed algebras \( \mathcal{C}(ISU(2,2)), \mathcal{C}(ISU(2,2)) \) provide noncommutative matrix entries of quantum \( SU(2,2) \) group. The noncommutativity of matrix group elements \( g_A^B \in SU(2,2) \) is determined by RTT relations (see, e.g., [7,26])

\[
R^{AC}_{\bar{B}D} g^{B_{\bar{E}}}_{\bar{L}} \bar{E}^{\bar{F}} = g^{A_{\bar{E}}}_{\bar{L}} R^{BD}_{\bar{E}F}
\]

(79)

where the \( R \)-matrix is expressed by the following cotwist formula

\[
R^{AC}_{\bar{B}D} = (\mathcal{F}^T \mathcal{F}^{-1})^{AC}_{\bar{B}D}.
\]

(80)
The cotwist $F_{BD}^{AC}$ dual to the twist $F$ is determined by the following evaluation map:

$$F_{BD}^{AC}(s, s') \equiv \langle F|s_B^A \otimes s_D^C > .$$ (81)

The noncommutative multiplication formula of cotwisted SU(2, 2) matrix elements is given by the formula

$$s \odot s' = F(s_{(1)}^{(1)} \cdot s_{(2)}^{(2)} \cdot F^{-1}(s_{(3)}^{(3)} \cdot s_{(4)}^{(4)}).$$ (82)

Because the twistor coordinates and momenta $T^I, \bar{T}^I$ as well as the complex Minkowski space-time coordinates are expressed by the element of SU(2, 2) group (see (25)–(27)), the NC multiplication rule (82) defines the noncommutativity of cotwist-deformed twistor coordinates $\bar{t}_A, \bar{t}_A$ as well as the complex quantum Minkowski coordinates $2^{3\bar{F}}$. Further, using the cotwist-deformed multiplication rule (82), one can also derive the cotwist deformation of incidence relations (7).

4. Outlook

The aim of this paper is the presentation of some aspects of the NC framework for quantum-deformed twistors. Our inspiration came from the paper by Penrose [27] who under the name of palatial twistors introduced the “physical” class of $\Theta_{AB}$-deformed dS (de Sitter) twistors, with the parameters $\theta_{AB}$ determined geometrically by real de Sitter infinity twistor $I_{AB}$ (see (11)).

In our scheme, we reduce the multiparameter deformations effectively to the one-Parametric ones by using the geometric degree of freedom which describes the variable Planck length or variable Planck mass. As an example, one can provide the generalized $\kappa$-deformations depending on the constant four-vector $a_\mu$, generating the following $a_\mu$-dependent quantum space-times [60]:

$$[\hat{x}_\mu, \hat{x}_\nu] = i(a_\mu x_\nu - a_\nu x_\mu)$$ (83)

where $a_\mu = \lambda a_\mu^{(0)} (|\lambda| = L, [a_\mu^{(0)}] = L^0)$ and the fourvector $a_\mu^{(0)}$ are chosen as normalized, namely $(a_\mu^{(0)^2} = -1$ for standard time-like $\kappa$-deformation, $a_\mu^{(0)^2} = 1$ for tachyonic space-like $\kappa$-deformation and $a_\mu^{(0)^2} = 0$ for light cone $\kappa$-deformation.

The following are some directions in which one can continue the studies presented in this paper:

1. If we consider the twistor correspondence with complexified space-times, one should introduce the pair of dual twistors $(t_A, w_A; t_A w^A = 0)$ called ambitwistors, not linked by complex conjugation (Hermitian conjugation in quantized case), which provide the description of complex null geodesies in complexified Minkowski space $M^C_{d=4}$ [61–63]. In such a case, if $w^\lambda = (\lambda^\alpha, \mu_\alpha)$, one can introduce the symplectic 2-form (see (13))

$$\hat{\Theta}_2 = d(\hat{I}^{AB} w_A d w_B) = \hat{I}^{AB} d w_A \wedge d w_B = \frac{\lambda}{6} d\lambda_\alpha \wedge d\lambda^\alpha + d\mu_\alpha \wedge d\mu_\alpha$$ (84)

where $\lambda = \frac{1}{r^2}$ appears as the second cosmological constant. In such a case, the curvatures $R$ and $r$ associated with twistors $t_A$ and $w_A$ can be different; in particular, if $R \gg r$, they may provide the tool to describe two de Sitter geometries characterizing the cosmological macroscopic distances and the ultrashort Planckian ones. It appears that the duality map $t_A \leftrightarrow w_A$, which implies the interchange relation $R \leftrightarrow r$, can be linked with Born duality relation (see, e.g., [39,40,64,65]). One can speculate that the presence of the pair of dual radii $(r, R)$ in ambitwistor framework can lead to the description of quantum effects simultaneously at ultrashort (radius $r$) and at macroscoping (radius $R$) cosmological distances.

2. The $D = 4$ twistorial construction presented here can be quite easily generalized to $D = 3$ and $D = 6$ twistors, described by the $D = 3$ and $D = 6$ conformal groups $Sp(4;\mathbb{R}) \simeq O(3,2)$ and $U_6(4;\mathbb{H}) \simeq O(6,2)$. We add that the $D = 4$ conformal group...
SU(2, 2) can also be described as the antiunitary one \(U_{\alpha}(4; \mathbb{C})\) [66,67]. In such a way, we deal with the antiunitary family of groups \(U_{\alpha}(4; \mathbb{F})\), where field \(\mathbb{F} = R, C, H\). In addition, since the 1970s, supertwistors [68] have been studied, which are a well recognized tool in the studies of superparticles, superstrings, supersymmetric gauge theories and supergravity.

3. Various quantum deformations of \(SU(2, 2)\) and of its complexification \(SL(4; \mathbb{C})\) have been used since the 1990s ([69–72]; see also [73]). One can recall that S. Zakrzewski, after classifying the \(D = 4\) Lorentz matrices [74], proposed the algebraic technique to classify the classical r-matrices of Poincaré algebras [75]. After providing the classical \(SU(2, 2)\) r-matrices, it should be possible to obtain also the r-matrices for inhomogeneous (pseudo) unitary algebras.

4. Recently, the twistorial field-theoretic approach to formulate gauge theories and gravity in twistor space has been promoted (see, e.g., [76,77]), with the dynamics described by twistorial actions. By using local twistor geometry, one obtains in a natural way conformal gravity [78]; the twistorial model of Einstein gravity with non-zero cosmological constant can also be obtained by embedding into twistorial conformal gravity [76,77]. The formulation of QG in twistorial framework, by analogy with the approach presented in [5], may require as well the noncommutative twistorial quantum geometry.
