A VARIATIONAL CHARACTERIZATION OF
LANGEVIN–SMOLUCHOWSKI DIFFUSIONS∗

TO THE MEMORY OF MARK H.A. DAVIS, 1945 – 2020

Ioannis Karatzas† Bertram Tschiderer‡

9th October 2020

ABSTRACT. We show that Langevin–Smoluchowski measure on path space is invariant under time-reversal, followed by stochastic control of the drift with a novel entropic-type criterion. Repeated application of these forward-backward steps leads to a sequence of stochastic control problems, whose initial/terminal distributions converge to the Gibbs probability measure of the diffusion, and whose values decrease to zero along the relative entropy of the Langevin–Smoluchowski flow with respect to this Gibbs measure.

MSC 2010 subject classifications: Primary 93E20, 94A17; secondary 35Q84, 60G44, 60J60

Keywords and phrases: Langevin–Smoluchowski diffusion, relative entropy, Gibbs measure, time reversal, stochastic control, alternating forward-backward dynamics

1 INTRODUCTION

Diffusions of Langevin–Smoluchowski type have some important properties. They possess invariant (Gibbs) probability measures described very directly in terms of their potentials and towards which, under appropriate conditions, their time-marginals converge as time increases to infinity and in a manner that conforms to the second law of thermodynamics: the relative entropy of the current distribution, with respect to the invariant one, decreases to zero. The seminal paper [JKO98] revealed another remarkable, local aspect of this decrease towards equilibrium: the family of time-marginals is, at (almost) every point in time, a curve of steepest descent relative to perturbations of the potential, when distances are measured according to the Wasserstein metric in configuration space.

We establish in this paper yet another variational property of such diffusions, this time a global one: their law is invariant under the combined effects of time-reversal, and of stochastic control of the drift under a novel, entropic-type criterion. Here, one minimizes over admissible controls the

∗We are grateful to Promit Ghosal for his interest in this work and for encouraging us to consider its iterative aspects.

relative entropy of the “terminal” state with respect to the invariant measure, plus an additional term thought of as “entropic cost of time-reversal”: the difference in relative entropy with respect to the Langevin–Smoluchowski measure, computed based on the “terminal” state as opposed to the entire path. To the best of our knowledge, such a cost criterion is considered here for the first time.

The setting under consideration bears similarities to the celebrated Schrödinger bridge problem, but also considerable differences. Both problems are posed on a fixed time horizon of finite length, and both involve the relative entropy with respect to the invariant measure. But here this entropy is modified by the addition of the above-mentioned entropic cost of time-reversal, and there is no fixed, target distribution on the terminal state. Yet the trajectory that emerges as the solution of the stochastic control problem has time-marginals that replicate exactly those of the original Langevin–Smoluchowski flow, whence the “invariance” property mentioned in the abstract.

We refer to [Léo14a], [CGP16], [CGP20] for overviews on the classical Schrödinger bridge problem, and to the recent paper [BCGL20] for a detailed study of the mean-field Schrödinger problem. A related controllability problem for a Fokker–Planck equation and its connection to Schrödinger systems and stochastic optimal control, is considered in [Bla92]. More information about the Schrödinger equation, diffusion theory, and time reversal, can be found in the book [Nag93].

1.1 Preview

In Section 2 we introduce the Langevin–Smoluchowski measure \( \mathbb{P} \) on path space, under which the canonical process \((X(t))_{t \geq 0}\) has dynamics (2.1) with initial distribution \(P(0)\). Then, in Section 3, this process is studied under time-reversal. That is, we fix a terminal time \( T \in (0, \infty) \) and consider the time-reversed diffusion \( \overline{X}(s) = X(T - s), 0 \leq s \leq T \). Classical theory of time reversal shows that \( \overline{X} \) is again a diffusion process, and gives an explicit description of its dynamics.

Section 4 develops our main result, Theorem 4.1. An equivalent change of probability measure \( \mathbb{P}^\gamma \sim \mathbb{P} \) adds to the drift of \( \overline{X} \) a measurable, adapted process \( \gamma(T - s), 0 \leq s \leq T \). In broad brushes, this allows us to define, in terms of relative entropies, the quantities

\[
H^\gamma := H(\mathbb{P}^\gamma | Q) \bigg|_{\sigma(\overline{X}(T))}, \quad D^\gamma := H(\mathbb{P}^\gamma | \mathbb{P}) \bigg|_{\sigma(\overline{X})} - H(\mathbb{P}^\gamma | \mathbb{P}) \bigg|_{\sigma(\overline{X}(T))}.
\]

(1.1)

Here, \( Q \) is the probability measure on path space, inherited from the Langevin–Smoluchowski dynamics (2.1) with initial distribution given by the invariant Gibbs probability measure \( Q \). Theorem 4.1 establishes then the variational characterization

\[
\inf_\gamma (H^\gamma + D^\gamma) = H(\mathbb{P}(T) | Q),
\]

(1.2)

where \( \mathbb{P}(T) \) denotes the distribution of the random variable \( X(T) \) under \( \mathbb{P} \). The process \( \gamma^* \) that realizes the infimum in (1.2) gives rise to a probability measure \( \mathbb{P}^{\gamma^*} \), under which the time-reversed diffusion \( \overline{X} \) is of Langevin–Smoluchowski type in its own right, but now with initial distribution \( P(T) \). In other words, with the constraint of minimizing the sum of the quantities \( H^\gamma \) and \( D^\gamma \) of (1.1), Langevin–Smoluchowski measure on path space is invariant under time-reversal.

Sections 5 and 6 develop ramifications of the main result, including the following consistency property: starting with the time-reversal \( \overline{X} \) of the Langevin–Smoluchowski diffusion, the solution of a related optimization problem, whose value is now \( H(\mathbb{P}(2T) | Q) \), leads to the original forward Langevin–Smoluchowski dynamics, but now with initial distribution \( P(2T) \). Iterating these procedures we obtain an alternating sequence of forward-backward Langevin–Smoluchowski dynamics with initial distributions converging to \( Q \), along which the values of the corresponding optimization problems as in (1.2) are given by \( (H(\mathbb{P}(kT) | Q))_{k \in \mathbb{N}} \) and decrease to zero.
2 The setting

Let us consider a Langevin–Smoluchowski diffusion process \((X(t))_{t \geq 0}\) of the form
\[
\text{d}X(t) = - \nabla \Psi(X(t)) \, \text{d}t + \text{d}W(t),
\]
with values in \(\mathbb{R}^n\). Here \((W(t))_{t \geq 0}\) is standard \(n\)-dimensional Brownian motion, and the “potential” \(\Psi : \mathbb{R}^n \to [0, \infty)\) is a \(C^\infty\)-function growing, along with its derivatives of all orders, at most exponentially as \(|x| \to \infty\). We posit also an “initial condition” \(X(0) = \Xi\), a random variable independent of the driving Brownian motion and with given distribution \(P(0)\); for concreteness, we shall assume that this initial distribution has a continuous probability density function \(p_0(\cdot)\) with finite second moment.

Under these conditions, the Langevin–Smoluchowski equation (2.1) admits a pathwise unique, strong solution, up until an “explosion time” \(\varepsilon\); such explosion never happens, i.e., \(P(\varepsilon = \infty) = 1\), if in addition the coercivity condition (2.9) below holds. This condition propagates the finiteness of the second moment to the collection of time-marginal distributions \(P(t) = \text{Law}(X(t)), \ t \geq 0\), which are then determined uniquely. In fact, adapting the arguments in [Rog85] to the present situation, we check that each time-marginal distribution \(P(t)\) has probability density \(p(t, \cdot)\) such that the resulting function \((t, x) \mapsto p(t, x)\) is continuous and strictly positive on \((0, \infty) \times \mathbb{R}^n\); differentiable with respect to the spatial variable \(x\) for each \(t > 0\); and such that the logarithmic derivative \((t, x) \mapsto \nabla \log p(t, x)\) is continuous on \((0, \infty) \times \mathbb{R}^n\). These arguments also lead to the Fokker–Planck [Fri75, Gar09, Ris96, Sch80], or forward Kolmogorov [Kol31], equation
\[
\partial p(t, x) = \frac{1}{2} \Delta p(t, x) + \text{div} (\nabla \Psi(x) p(t, x)), \quad (t, x) \in (0, \infty) \times \mathbb{R}^n
\]
with initial condition
\[
p(0, x) = p_0(x), \quad x \in \mathbb{R}^n.
\]
Here and throughout this paper, \(\partial\) denotes differentiation with respect to the temporal argument.

2.1 Invariant measure, likelihood ratio, and relative entropy

We introduce now the function
\[
q(x) := e^{-2\Psi(x)}, \quad x \in \mathbb{R}^n
\]
and note that it satisfies the stationary version
\[
\frac{1}{2} \Delta q(x) + \text{div} (\nabla \Psi(x) q(x)) = 0, \quad x \in \mathbb{R}^n
\]
of the forward Kolmogorov equation (2.2). We introduce also the \(\sigma\)-finite measure \(Q\) on the Borel subsets \(\mathcal{B}(\mathbb{R}^n)\) of \(\mathbb{R}^n\), which has density \(q\) as in (2.4) with respect to \(n\)-dimensional Lebesgue measure. This measure \(Q\) is invariant for the diffusion of (2.1); see Exercise 5.6.18 in [KS88]. When finite, \(Q\) can be normalized to an invariant probability measure for (2.1), to which the time-marginals \(P(t)\) “converge” as \(t \to \infty\); more on this convergence below. We shall always assume tacitly that such a normalization has taken place, when \(Q\) is finite.

One way to think of the above-mentioned convergence, is by considering the likelihood ratio
\[
\ell(t, x) := \frac{p(t, x)}{q(x)}, \quad (t, x) \in (0, \infty) \times \mathbb{R}^n.
\]
It follows from (2.2), (2.5) that this function satisfies the backward Kolmogorov equation
\[
\partial \ell(t, x) = \frac{1}{2} \Delta \ell(t, x) - \langle \nabla \ell(t, x), \nabla \Psi(x) \rangle, \quad (t, x) \in (0, \infty) \times \mathbb{R}^n.
\]
In terms of the likelihood ratio function (2.6), let us consider now the relative entropy

$$H(P(t) \mid Q) := \mathbb{E}_P \left[ \log \ell(t, X(t)) \right] = \int_{\mathbb{R}^n} \log \left( \frac{p(t, x)}{q(x)} \right) p(t, x) \, dx, \quad t \geq 0$$

(2.8)
of the probability distribution $P(t)$ with respect to the invariant measure $Q$. This is a well-defined number in $[0, \infty]$, if $Q$ is a probability measure. As we are not imposing this as a blanket assumption, we shall rely on Appendix C of [KST20b], where it is shown that the relative entropy $H(P(t) \mid Q)$ is well-defined and takes values in $(-\infty, \infty)$, whenever $P(t)$ belongs to the space $\mathcal{P}_2(\mathbb{R}^n)$ of probability measures with finite second moment (see also [Léo14b] for a more general discussion). This, in turn, is the case whenever $P(0)$ has finite second moment, and the coercivity condition

$$\forall x \in \mathbb{R}^n, |x| \geq R: \quad \langle x, \nabla \Psi(x) \rangle \geq -c|x|^2$$

(2.9)
is satisfied by the potential $\Psi$ in (2.1), for some real constants $c \geq 0$ and $R \geq 0$; see the first problem on page 125 of [Fri75], or Appendix B in [KST20b]. The prototypical such potential is $\Psi(x) = \frac{1}{2} |x|^2$, leading to Ornstein–Uhlenbeck dynamics in (2.1); but $\Psi \equiv 0$ and the “double well” $\Psi(x) = (x^2 - a^2)^2$ for $a > 0$, are also allowed.

We shall impose throughout the coercivity condition (2.9), as well as the integrability requirements

$$\int_{\mathbb{R}^n} |x|^2 p_0(x) \, dx < \infty, \quad \int_{\mathbb{R}^n} \log \left( \frac{p_0(x)}{q(x)} \right) p_0(x) \, dx < \infty.$$  

(2.10)

Of these two requirements, the first amounts to $P(0) \in \mathcal{P}_2(\mathbb{R}^n)$, as has been already alluded to. The second requirement amounts to $H(P(0) \mid Q) < \infty$ in (2.8); and the decrease of the relative entropy$^1$ function $[0, \infty) \ni t \mapsto H(P(t) \mid Q) \in (-\infty, \infty]$ implies then that the quantity in (2.8) is finite for all $t \geq 0$.

In fact, under the above-stated conditions, the rate of decrease for the relative entropy, measured with respect to distances traveled in $\mathcal{P}_2(\mathbb{R}^n)$ in terms of the quadratic Wasserstein metric

$$W_2(\mu, \nu) = \left( \inf_{Y \sim \mu, Z \sim \nu} \mathbb{E} |Y - Z|^2 \right)^{1/2}, \quad \mu, \nu \in \mathcal{P}_2(\mathbb{R}^n)$$

(2.11)

(cf. [Vil03, AGS08, AG13]) is, at Lebesgue-almost all times $t_0 \in [0, \infty)$, the steepest possible along the Langevin–Smoluchowski curve $(P(t))_{t \geq 0}$ of probability measures. Here, we are comparing the curve $(P(t))_{t \geq 0}$ against all such curves $(P^B(t))_{t \geq t_0}$ of probability measures generated as in (2.1) — but with an additional drift $\nabla B$ for suitable (smooth and compactly supported) perturbations $B$ of the potential $\Psi$ in (2.1). This local optimality property of Langevin–Smoluchowski diffusions is due to [JKO98]; it was established by [KST20a] in the form just described. We develop in this paper yet another, global this time, optimality property for such diffusions.

2.2 The probabilistic setting

In (2.8) and throughout this paper, we are denoting by $\mathbb{P}$ the unique probability measure on the space $\Omega = C([0, \infty); \mathbb{R}^n)$ of continuous, $\mathbb{R}^n$-valued functions, under which the canonical coordinate process $X(t, \omega) = \omega(t)$, $t \geq 0$ has the property that

$$W(t) := X(t) - X(0) + \int_0^t \nabla \Psi(X(\theta)) \, d\theta, \quad t \geq 0$$

(2.12)

$^1$A classical aspect of thermodynamics; for a proof of this fact in the present context, see Theorem 3.1 in [KST20a]. When $Q$ is a probability measure, the relative entropy $H(P(t) \mid Q)$ decreases all the way to zero as $t \to \infty$, i.e.,

$$\lim_{t \to \infty} H(P(t) \mid Q) = 0,$$

quantifying the convergence of $P(t)$ to $Q$ in total variation, in light of the Pinsker–Csiszár inequality $2 \|P(t) - Q\|_{TV}^2 \leq H(P(t) \mid Q)$. This entropic decrease to zero is exponentially fast, whenever the Hessian of $\Psi$ dominates a positive multiple of the identity matrix.
is standard $\mathbb{R}^n$-valued Brownian motion, and independent of the random variable $X(0)$ with distribution
\[ P[X(0) \in A] = \int_A p_0(x) \, dx, \quad A \in \mathcal{B}(\mathbb{R}^n). \] (2.13)

The $P$-Brownian motion $(W(t))_{t \geq 0}$ of (2.12) is adapted to, in fact generates, the canonical filtration $\mathcal{F} = (\mathcal{F}(t))_{t \geq 0}$ with
\[ \mathcal{F}(t) := \sigma(X(s) : 0 \leq s \leq t). \] (2.14)

By analogy to the terminology “Wiener measure”, we call $P$ the “Langevin–Smoluchowski measure” associated with the potential $\Psi$.

### 3 Reversal of time

The densities $p(t, \cdot)$ and $q(\cdot)$ satisfy the forward Kolmogorov equations (2.2) and (2.5), respectively. Whereas, their likelihood ratio $\ell(t, \cdot)$ in (2.6) satisfies the backward Kolmogorov equation (2.7). This suggests that, in the study of relative entropy and its temporal or spatial dissipation, it might make sense to look at the underlying Langevin–Smoluchowski diffusion under time-reversal. Such an approach proved very fruitful in [DPP89], [FJ16] and [KST20a]; it will be important in our context here as well.

Thus, we fix an arbitrary terminal time $T \in (0, \infty)$ and consider the time-reversed process
\[ \overline{X}(s) := X(T - s), \quad \overline{\sigma}(s) := \sigma(\overline{X}(u) : 0 \leq u \leq s); \quad 0 \leq s \leq T \] (3.1)
along with the filtration $\overline{\mathcal{G}} = (\overline{\mathcal{G}}(s))_{0 \leq s \leq T}$ this process generates. Then standard theory on time-reversal shows that
\[ \overline{W}(s) := \overline{X}(s) - \overline{X}(0) + \int_0^s \left( \nabla \Psi(\overline{X}(u)) - \nabla L(T - u, \overline{X}(u)) \right) \, du, \quad 0 \leq s \leq T \] (3.2)
is, under $P$, a $\overline{\mathcal{G}}$-standard Brownian motion with values in $\mathbb{R}^n$ and independent of $\overline{X}(0) = X(T)$ (see, for instance, [Föl85, Föl86], [HP86], [Mey94], [Nel01], and [Par86] for the classical results; an extensive presentation of the relevant facts regarding the time reversal of diffusion processes can be found in Appendix G of [KST20b]).

Here
\[ L(t, x) := \log \ell(t, x), \quad (t, x) \in (0, \infty) \times \mathbb{R}^n \] (3.3)
is the logarithm of the likelihood ratio function in (2.6); and on the strength of (2.7), this function solves the semilinear Schrödinger-type equation
\[ \partial L(t, x) = \frac{1}{2} \Delta L(t, x) - \langle \nabla L(t, x), \nabla \Psi(x) \rangle + \frac{1}{2} |\nabla L(t, x)|^2. \] (3.4)

Another way to express this, is by saying that the so-called Hopf–Cole transform $\ell = e^L$ turns the semilinear equation (3.4), into the linear backward Kolmogorov equation (2.7). This observation is not new; it has been used in stochastic control to good effect by Fleming [Fle77, Fle82], Holland [Hol77], and in a context closer in spirit to this paper by Dai Pra and Pavon [DPP90], Dai Pra [DP91].

### 4 A stochastic control problem

Yet another way to cast the equation (3.4), is in the Hamilton–Jacobi–Bellman form
\[ \partial L(t, x) = \frac{1}{2} \Delta L(t, x) - \langle \nabla L(t, x), \nabla \Psi(x) \rangle - \min_{g \in \mathbb{R}^n} \left( \langle \nabla L(t, x), g \rangle + \frac{1}{2} |g|^2 \right), \] (4.1)
where the minimization is attained by the gradient $g_s = -\nabla L(t, x)$. This, in turn, suggests a stochastic control problem related to the backwards dynamics

$$d\bar{X}(s) = \left(\nabla L(T - s, \bar{X}(s)) - \nabla\Psi(\bar{X}(s))\right) ds + d\bar{W}(s)$$  \hspace{1cm} (4.2)

of (3.2), which we formulate now as follows.

For any measurable process $[0, T] \times \Omega \ni (t, \omega) \mapsto \gamma(t, \omega) \in \mathbb{R}^n$, such that the time-reversed process $\gamma(T - s), 0 \leq s \leq T$ is adapted to the backward filtration $\mathcal{G}$ of (3.1), and that satisfies the condition

$$\mathbb{P}\left[\int_0^T |\gamma(T - s)|^2 ds < \infty\right] = 1,$$  \hspace{1cm} (4.3)

we consider the exponential $(\mathcal{G}, \mathbb{P})$-local martingale

$$Z^\gamma(s) := \exp\left(\int_0^s \left(\gamma(T - u), d\bar{W}(u) - \frac{1}{2} \int_0^s |\gamma(T - u)|^2 du\right)\right), \quad 0 \leq s \leq T.$$  \hspace{1cm} (4.4)

We denote by $\Gamma$ the collection of all processes $\gamma$ as above, for which $Z^\gamma$ is a true $(\mathcal{G}, \mathbb{P})$-martingale. This collection is not empty: it contains all such uniformly bounded processes $\gamma$, and quite a few more (e.g., conditions of Novikov [KS88, Corollary 3.5.13] and Kazamaki [RY99, Proposition VIII.1.14]).

Now, for every $\gamma \in \Gamma$, we introduce an equivalent probability measure $\mathbb{P}^\gamma \sim \mathbb{P}$ on path space, via

$$\frac{d\mathbb{P}^\gamma}{d\mathbb{P}}|_{\gamma(s)} = Z^\gamma(s), \quad 0 \leq s \leq T.$$  \hspace{1cm} (4.5)

Then, by the Girsanov theorem [KS88, Theorem 3.5.1], the process

$$\bar{W}^\gamma(s) := \bar{W}(s) - \int_0^s \gamma(T - u) du, \quad 0 \leq s \leq T$$  \hspace{1cm} (4.6)

is standard $\mathbb{R}^n$-valued $\mathbb{P}^\gamma$-Brownian motion of the filtration $\mathcal{G}$, thus independent of the random variable $\bar{X}(0) = X(T)$. Under the probability measure $\mathbb{P}^\gamma$, the backwards dynamics of (4.2) take the form

$$d\bar{X}(s) = \left(\nabla L(T - s, \bar{X}(s)) + \gamma(T - s) - \nabla\Psi(\bar{X}(s))\right) ds + d\bar{W}^\gamma(s);$$  \hspace{1cm} (4.7)

and it follows readily from this decomposition and the semilinear parabolic equation (3.4), that the process

$$M^\gamma(s) := L(T - s, \bar{X}(s)) + \frac{1}{2} \int_0^s |\gamma(T - u)|^2 du, \quad 0 \leq s \leq T$$  \hspace{1cm} (4.8)

is a local $\mathcal{G}$-submartingale under $\mathbb{P}^\gamma$, with decomposition

$$dM^\gamma(s) = \frac{1}{2} \left|\nabla L(T - s, \bar{X}(s)) + \gamma(T - s)\right|^2 ds + \left\langle \nabla L(T - s, \bar{X}(s)), d\bar{W}^\gamma(s)\right\rangle.$$  \hspace{1cm} (4.9)

In fact, introducing the sequence

$$\sigma_n := \inf\left\{s \geq 0 : \int_0^s \left(\left|\nabla L(T - u, \bar{X}(u))\right|^2 + |\gamma(T - u)|^2\right) du \geq n\right\} \wedge T, \quad n \in \mathbb{N}_0$$  \hspace{1cm} (4.10)

of $\mathcal{G}$-stopping times with $\sigma_n \uparrow T$, we see that the stopped process $M^\gamma(\cdot \wedge \sigma_n)$ is a $\mathcal{G}$-submartingale under $\mathbb{P}^\gamma$, for every $n \in \mathbb{N}_0$. In particular, we observe

$$H(P(T) | Q) = \mathbb{E}_{P}[L(T, X(T))] = \mathbb{E}_{P^\gamma}[L(T, \bar{X}(0))]
\leq \mathbb{E}_{P^\gamma}\left[L(T - \sigma_n, \bar{X}(\sigma_n)) + \frac{1}{2} \int_0^{\sigma_n} \left|\gamma(T - u)\right|^2 du\right],$$  \hspace{1cm} (4.11)

where $\sigma_n := \inf\{s \geq 0 : \int_0^s \left(\left|\nabla L(T - u, \bar{X}(u))\right|^2 + |\gamma(T - u)|^2\right) du \geq n\} \wedge T, \quad n \in \mathbb{N}_0$.
since \( P^\gamma = P \) on \( \mathcal{G}(0) = \sigma(\overline{X}(0)) = \sigma(X(T)) \). Now (4.11) holds for every \( n \in \mathbb{N}_0 \), thus
\[
H(P(T) \mid Q) \leq \liminf_{n \to \infty} E_{P^\gamma} \left[ L(T - \sigma_n, \overline{X}(\sigma_n)) + \frac{1}{2} \int_0^{\sigma_n} |\gamma(T-u)|^2 \, du \right]. \tag{4.12}
\]

But as we remarked already, the minimum in (4.1) is attained by \( g_* = -\nabla L(t, x) \); likewise, the drift term in (4.9) vanishes, if we select the process \( \gamma_* \in \Gamma \) via
\[
\gamma_*(t, \omega) := -\nabla L(t, \omega(t)), \quad \text{thus} \quad \gamma_*(T-s) = -\nabla L(T-s, \overline{X}(s)), \quad 0 \leq s \leq T. \tag{4.13}
\]
With this choice, the backwards dynamics of (4.7) take the form
\[
d\overline{X}(s) = -\nabla \Psi(\overline{X}(s)) \, ds + d\overline{W}^{\gamma_*}(s); \tag{4.14}
\]
that is, precisely of the Langevin–Smoluchowski type (2.1), but now with the “initial condition” \( \overline{X}(0) = X(T) \) and independent driving \( \mathcal{G} \)-Brownian motion \( \overline{W}^{\gamma_*} \), under \( P^{\gamma_*} \). Since \( P^{\gamma_*} = P \) holds on the \( \sigma \)-algebra \( \mathcal{G}(0) = \sigma(\overline{X}(0)) = \sigma(X(T)) \), the initial distribution of \( \overline{X}(0) \) under \( P^{\gamma_*} \) is equal to \( P(T) \). Furthermore, with \( \gamma = \gamma_* \), the process of (4.8), (4.9) becomes a \( P^{\gamma_*} \)-local martingale, namely
\[
M^{\gamma_*}(s) = L(T, X(T)) + \int_0^s \langle \nabla L(T-u, \overline{X}(u)), d\overline{W}^{\gamma_*}(u) \rangle, \quad 0 \leq s \leq T; \tag{4.15}
\]
and we have equality in (4.11), thus also
\[
H(P(T) \mid Q) = \lim_{n \to \infty} E_{P^{\gamma_*}} \left[ L(T - \sigma_n, \overline{X}(\sigma_n)) + \frac{1}{2} \int_0^{\sigma_n} |\gamma_*(T-u)|^2 \, du \right]. \tag{4.16}
\]

We conclude that the infimum over \( \gamma \in \Gamma \) of the right-hand side in (4.12) is attained by the process \( \gamma_* \) of (4.13), which gives rise to the Langevin–Smoluchowski dynamics (4.14) for the time-reversed process \( \overline{X}(s) = X(T-s), 0 \leq s \leq T, \) under \( P^{\gamma_*} \). We formalize this discussion as follows.

**Theorem 4.1.** Consider the stochastic control problem of minimizing over the class \( \Gamma \) of measurable, adapted processes \( \gamma \) satisfying (4.3) and inducing an exponential martingale \( Z^\gamma \) in (4.4), with the notation of (4.10) and with the backwards dynamics of (4.7), the expected cost
\[
I(\gamma) := \liminf_{n \to \infty} E_{P^\gamma} \left[ L(T - \sigma_n, \overline{X}(\sigma_n)) + \frac{1}{2} \int_0^{\sigma_n} |\gamma(T-u)|^2 \, du \right]. \tag{4.17}
\]

Under the assumptions of Section 2, the infimum \( \inf_{\gamma \in \Gamma} I(\gamma) \) is equal to the relative entropy \( H(P(T) \mid Q) \) and is attained by the “score process” \( \mathcal{G}_* \) of (4.13). This choice leads to the backwards Langevin–Smoluchowski dynamics (4.14), and with \( \gamma = \gamma_* \) the limit in (4.17) exists as in (4.16).

**Proof.** The last thing we need to check for the proof of Theorem 4.1, is that the minimizing process \( \gamma_* \) of (4.13) belongs indeed to the collection \( \Gamma \) of admissible processes. By its definition, the process \( \gamma_* \) is measurable, and its time-reversal is adapted to the backward filtration \( \mathcal{G} \) of (3.1). Theorem 4.1 in [KST20a] gives
\[
E_P \left[ \int_0^T |\nabla L(T-u, \overline{X}(u))|^2 \, du \right] = E_P \left[ \int_0^T |\nabla L(\theta, X(\theta))|^2 \, d\theta \right] < \infty, \tag{4.18}
\]
which implies a fortiori that the condition in (4.3) is satisfied for \( \gamma = \gamma_* \).

It remains to show that the process \( Z^{\gamma_*} \) defined in the manner of (4.4), is a true martingale. A very mild dose of stochastic calculus leads to
\[
dL(T-s, \overline{X}(s)) = \langle \nabla L(T-s, \overline{X}(s)), d\overline{W}(s) \rangle + \frac{1}{2} |\nabla L(T-s, \overline{X}(s))|^2 \, ds \tag{4.19}
\]
on account of (3.4), (4.2). Therefore, we have
\[
\int_0^s \langle \gamma_s(T-u), d\overline{W}(u) \rangle - \frac{1}{2} \int_0^s |\gamma_s(T-u)|^2 \, du \\
= - \int_0^s \langle \nabla L(T-u, \overline{X}(u)), d\overline{W}(u) \rangle - \frac{1}{2} \int_0^s |\nabla L(T-u, \overline{X}(u))|^2 \, du \\
= L(T, X(T)) - L(T-s, X(T-s)) = \log \left( \frac{\ell(T, X(T))}{\ell(T-s, X(T-s))} \right),
\]
which expresses the exponential process of (4.4) with \( \gamma = \gamma_s \) as
\[
Z^{\gamma_s}(s) = \frac{\ell(T, X(T))}{\ell(T-s, X(T-s))}, \quad 0 \leq s \leq T.
\]

Now, let us argue that the process \( Z^{\gamma_s} \) is a true \((\overline{G}, \overline{P})\)-martingale. It is a positive local martingale, thus a supermartingale. It will be a martingale, if it has constant expectation. But \( Z^{\gamma_s}(0) \equiv 1 \), so it is enough to show that \( \overline{E}_P[Z^{\gamma_s}(T)] = 1 \). Let us denote by \( P(s, y; t, \xi) \) the transition kernel of the Langevin–Smoluchowski dynamics, so that \( \overline{P}[X(s) \in dy, X(t) \in d\xi] = p(s, y) P(s, y; t, \xi) \, dy \, d\xi \) for \( 0 \leq s < t \leq T \) and \( (y, \xi) \in \mathbb{R}^n \times \mathbb{R}^n \). Then the invariance of \( Q \) gives
\[
\int_{\mathbb{R}^n} q(y) P(0, y; T, \xi) \, dy = q(\xi), \quad \xi \in \mathbb{R}^n;
\]
consequently
\[
\overline{E}_P[Z^{\gamma_s}(T)] = \overline{E}_P \left[ \frac{p(T, X(T))}{q(X(0))} \frac{q(X(0))}{p(0, X(0))} \right]
\]
\[
= \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} p(T, \xi) \frac{q(y)}{q(\xi)} p(0, y) P(0, y; T, \xi) \, dy \, d\xi
\]
\[
= \int_{\mathbb{R}^n} \frac{p(T, \xi)}{q(\xi)} \left( \int_{\mathbb{R}^n} q(y) P(0, y; T, \xi) \, dy \right) \, d\xi
\]
\[
= \int_{\mathbb{R}^n} p(T, \xi) \, d\xi = 1,
\]
implying that \( Z^{\gamma_s} \) is a true martingale and completing the proof of Theorem 4.1. \( \square \)

**Remark 4.2 (Reincarnation of time-marginals).** Let us denote by \( \overline{P}_s(s) \) the distribution of the random variable \( \overline{X}(s) = X(T-s) \) under the probability measure \( \overline{P}^{\gamma_s} \), for \( 0 \leq s \leq T \). Since \( \overline{X}(s) \) is under \( \overline{P}^{\gamma_s} \) a Langevin–Smoluchowski diffusion in its own right, we deduce
\[
\overline{P}_s(s) = P(T+s), \quad 0 \leq s \leq T
\]
on the strength of uniqueness in distribution for the Langevin–Smoluchowski flow, and of its time-homogeneity. In other words, the branch \( (P(T+s))_{0 \leq s \leq T} \) of the original Langevin–Smoluchowski curve of time-marginals, gets “reincarnated” as \( (\overline{P}_s(s))_{0 \leq s \leq T} \), the curve of time-marginals arising from the solution of the stochastic control problem in Theorem 4.1. But now, under the probability measure \( \overline{P}^{\gamma_s} \), the states of the Langevin–Smoluchowski diffusion \( \overline{X}(s) \) corresponding to the curve \( (\overline{P}_s(s))_{0 \leq s \leq T} \) traverse the time interval \([0, T]\) in the opposite temporal direction.
4.1 Entropic interpretation of the expected cost

Let us observe from (4.4) – (4.6) that

$$\log \left( \frac{dP^\gamma}{dP} \big|_{\mathcal{G}(\sigma_n)} \right) = \int_0^{\sigma_n} \langle \gamma(T-u), dW^\gamma(u) \rangle + \frac{1}{2} \int_0^{\sigma_n} \left| \gamma(T-u) \right|^2 du$$  (4.30)

holds for every $\gamma \in \Gamma$ and $n \in \mathbb{N}_0$. Thus, as the $P^\gamma$-expectation of the stochastic integral in (4.30) vanishes, the expected quadratic cost, or “energy”, term in (4.17) is itself a relative entropy:

$$E_{P^\gamma} \left[ \frac{1}{2} \int_0^{\sigma_n} \left| \gamma(T-u) \right|^2 du \right] = E_{P^\gamma} \left[ \log \left( \frac{dP^\gamma}{dP} \big|_{\mathcal{G}(\sigma_n)} \right) \right].$$  (4.31)

By contrast, when $Q$ is a probability measure on $\mathcal{B}(\mathbb{R}^n)$, and denoting by $Q$ the probability measure induced on $\Omega = C([0, \infty); \mathbb{R}^n)$ by the canonical process driven by the Langevin–Smoluchowski dynamics (2.1) with $Q$ as the distribution of $X(0)$, the first term in (4.17) can be cast as

$$E_{P^\gamma} \left[ L(T - \sigma_n, \overline{X}(\sigma_n)) \right] = E_{P^\gamma} \left[ \log \left( \frac{dP}{dQ} \big|_{\sigma(\sigma_n)} \right) \right] \quad (4.32)$$

$$= E_{P^\gamma} \left[ \log \left( \frac{dP^\gamma}{dQ} \big|_{\sigma(\sigma_n)} \right) \right] - E_{P^\gamma} \left[ \log \left( \frac{dP^\gamma}{dP} \big|_{\sigma(\sigma_n)} \right) \right].$$  (4.33)

It follows that, in this case, the expected cost of (4.17) is equal to the sum $H_n^\gamma + D_n^\gamma$ of two non-negative quantities:

$$H_n^\gamma := E_{P^\gamma} \left[ \log \left( \frac{dP^\gamma}{dQ} \big|_{\sigma(\sigma_n)} \right) \right],$$  (4.34)

the relative entropy of the probability measure $P^\gamma$ with respect to the probability measure $Q$, when both are restricted to the $\sigma$-algebra generated by the random variable $\overline{X}(\sigma_n)$; and

$$D_n^\gamma := E_{P^\gamma} \left[ \log \left( \frac{dP^\gamma}{dP} \big|_{\sigma(\sigma_n)} \right) \right] - E_{P^\gamma} \left[ \log \left( \frac{dP^\gamma}{dP} \big|_{\sigma(\sigma_n)} \right) \right];$$  (4.35)

the difference between the relative entropies of the probability measure $P^\gamma$ with respect to the probability measure $P$, when restricted to the $\sigma$-algebra generated by the collection of random variables $(\overline{X}(u \wedge \sigma_n))_{0 \leq u \leq T}$ and by the random variable $\overline{X}(\sigma_n)$, respectively. The difference in (4.35) is non-negative, because conditioning on a smaller $\sigma$-algebra can only decrease the relative entropy; this difference can be thought of as an “entropic cost of time-reversal”.

It develops from this discussion that the expected cost on the right-hand side of (4.17) is non-negative when $Q$ is a probability measure.

5 From local to square-integrable martingales

Whenever the process $M^\gamma$ of (4.8), (4.9) happens to be a true submartingale under $P^\gamma$ (as, for instance, with $\gamma \equiv 0$ on account of Theorem 4.1 in [KST20a]), the expected cost (4.17) takes the form

$$E_{P^\gamma} \left[ L(0, X(0)) + \frac{1}{2} \int_0^T \left| \gamma(T-u) \right|^2 du \right].$$  (5.1)

Likewise, we derive from Theorem 4.1 the identity

$$H(P(T) \mid Q) = E_{P^\gamma} \left[ L(0, X(0)) + \frac{1}{2} \int_0^T \left| \nabla L(T-u, \overline{X}(u)) \right|^2 du \right],$$  (5.2)
whenever the process $M^{\gamma^*}$ of (4.15) is a true $\mathbb{P}^{\gamma^*}$-martingale. This is the case, for instance, whenever
\[
\mathbb{E}_{\mathbb{P}^{\gamma^*}} \left[ \langle M^{\gamma^*}, M^{\gamma^*} \rangle(T) \right] = \mathbb{E}_{\mathbb{P}^{\gamma^*}} \left[ \int_0^T |\nabla L(T - u, \overline{X}(u))|^2 \, du \right] < \infty \tag{5.3}
\]
holds; and then the stochastic integral in (4.15) is an $L^2(\mathbb{P}^{\gamma^*})$-bounded martingale (see, for instance, [KS88, Proposition 3.2.10] or [RY99, Corollary IV.1.25]). Using (4.29), we can express the expectation of (5.3) more explicitly as
\[
\int_{\mathbb{R}^n} \int_0^T |\nabla \log \ell(t, x)|^2 \, p(2T - t) \, dt \, dx. \tag{5.4}
\]
The shift in the temporal variable makes it difficult to check whether the quantity in (5.4) is finite. At least, we have not been able to apply directly arguments similar to those in Theorem 4.1 of [KST20a], where the expectation (5.3) is taken with respect to the probability measure $\mathbb{P}$, in the manner of (4.18) (and thus, the argument $2T - t$ in (5.4) is replaced by $t$). This problem is consonant with the fact that the term in (4.32), (4.33) is not quite a relative entropy, but a linear combination of relative entropies.

The goal of this section is to find a square-integrable $\mathbb{P}^{\gamma^*}$-martingale $\overline{M}^{\gamma^*}$, which is closely related to the local martingale $M^{\gamma^*}$ of (4.15). The idea is to correct the shift in the temporal variable appearing in (5.4), by reversing time once again.

First, we need to introduce some notation. We denote by $\overline{p}(s, \cdot)$ the probability density function of the random variable $\overline{X}(s) = X(T - s)$ under the probability measure $\mathbb{P}^{\gamma^*}$, for $0 \leq s \leq T$. From (4.29), we deduce the relation
\[
\overline{p}(s, x) = p(T + s, x), \quad (s, x) \in [0, T] \times \mathbb{R}^n. \tag{5.5}
\]
The associated likelihood ratio function and its logarithm are defined respectively by
\[
\lambda(s, x) := \frac{\overline{p}(s, x)}{\overline{q}(x)}, \quad \Lambda(s, x) := \log \lambda(s, x) = L(T + s, x), \quad (s, x) \in [0, T] \times \mathbb{R}^n. \tag{5.6}
\]
From the definition (5.6), and the equations (3.4), (4.1), we see that the function $(s, x) \mapsto \Lambda(s, x)$ satisfies again the semilinear Schrödinger-type equation
\[
- \partial \Lambda(s, x) + \frac{1}{2} \Delta \Lambda(s, x) - \langle \nabla \Lambda(s, x), \nabla \Psi(x) \rangle = \min_{b \in \mathbb{R}^n} \left( \langle \nabla \Lambda(s, x), b \rangle + \frac{1}{2} |b|^2 \right). \tag{5.7}
\]
In the setting introduced above, the relative entropy with respect to $Q$ of the distribution $\overline{\mathbb{P}}_*(s)$ of $\overline{X}(s)$ under $\mathbb{P}^{\gamma^*}$ is
\[
H(\overline{\mathbb{P}}_*(s) \mid Q) = \mathbb{E}_{\mathbb{P}^{\gamma^*}} \left[ \Lambda(s, \overline{X}(s)) \right] = \int_{\mathbb{R}^n} \log \left( \frac{\overline{p}(s, x)}{\overline{q}(x)} \right) \overline{p}(s, x) \, dx, \quad 0 \leq s \leq T. \tag{5.8}
\]
Again, the assumption that $H(P(0) \mid Q)$ is finite, and the decrease of the relative entropy function $[0, \infty) \ni t \mapsto H(P(t) \mid Q) \in (-\infty, \infty]$, imply that the relative entropy in (5.8) is finite for all $0 \leq s \leq T$.

Finally, the relative Fisher information of $\overline{\mathbb{P}}_*(s)$ with respect to $Q$ is defined as
\[
I(\overline{\mathbb{P}}_*(s) \mid Q) := \mathbb{E}_{\mathbb{P}^{\gamma^*}} \left[ |\nabla \Lambda(s, \overline{X}(s))|^2 \right] = \int_{\mathbb{R}^n} |\nabla \Lambda(s, x)|^2 \overline{p}(s, x) \, dx, \quad 0 \leq s \leq T. \tag{5.9}
\]
5.1 Reversing time once again

Let us consider on the filtered probability space \((\Omega, \mathcal{F}, \mathbb{P}^{\gamma^*})\) the canonical process \((X(t))_{0 \leq t \leq T}\), whose time-reversal (3.1) satisfies the backwards Langevin–Smoluchowski dynamics (4.14). Reversing time once again, we find that \(X(t) = \overline{X}(T - t),\) \(0 \leq t \leq T\) satisfies the stochastic differential equation
\[
\text{d}X(t) = \left(\nabla \Lambda(T - t, X(t)) - \nabla \Psi(X(t))\right) \text{d}t + \text{d}W^{\gamma^*}(t), \quad 0 \leq t \leq T, \tag{5.10}
\]
where the process
\[
W^{\gamma^*}(t) := \overline{W}^{\gamma^*}(T - t) - \overline{W}^{\gamma^*}(T) - \int_{0}^{t} \nabla \log \overline{p}_{\gamma}(T - \theta, X(\theta)) \text{d}\theta, \quad 0 \leq t \leq T \tag{5.11}
\]
is Brownian motion on \((\Omega, \mathcal{F}, \mathbb{P}^{\gamma^*})\). We recall here Proposition 4.1 from [KST20b]. Comparing the equation (5.10) with (2.1), we see that the \(\mathbb{P}^{\gamma^*}\)-Brownian motion \((W^{\gamma^*}(t))_{0 \leq t \leq T}\) and the \(\mathbb{P}\)-Brownian motion \((W(t))_{0 \leq t \leq T}\) are related via
\[
W(t) = W^{\gamma^*}(t) + \int_{0}^{t} \nabla \Lambda(T - \theta, X(\theta)) \text{d}\theta, \quad 0 \leq t \leq T. \tag{5.12}
\]

5.2 The dynamics of the relative entropy process

We look now at the relative entropy process
\[
\Lambda(T - t, X(t)) = \log \left(\frac{\overline{p}_{\gamma}(T - t, X(t))}{q(X(t))}\right), \quad 0 \leq t \leq T \tag{5.13}
\]
on \((\Omega, \mathcal{F}, \mathbb{P}^{\gamma^*})\). Applying Itô’s formula and using the equation (5.7), together with the forward dynamics (5.10), we obtain the following result.

Proposition 5.1. On the filtered probability space \((\Omega, \mathcal{F}, \mathbb{P}^{\gamma^*})\), the relative entropy process (5.13) is a submartingale with stochastic differential
\[
\text{d}\Lambda(T - t, X(t)) = \frac{1}{2} \left| \nabla \Lambda(T - t, X(t)) \right|^2 \text{d}t + \left< \nabla \Lambda(T - t, X(t)) , \text{d}W^{\gamma^*}(t) \right> \tag{5.14}
\]
for \(0 \leq t \leq T\). In particular, the process
\[
\overline{M}^{\gamma^*}(t) := \Lambda(T - t, X(t)) - \Lambda(T, X(0)) - \frac{1}{2} \int_{0}^{t} \left| \nabla \Lambda(T - \theta, X(\theta)) \right|^2 \text{d}\theta, \quad 0 \leq t \leq T \tag{5.15}
\]
is an \(L^2(\mathbb{P}^{\gamma^*})\)-bounded martingale, with stochastic integral representation
\[
\overline{M}^{\gamma^*}(t) = \int_{0}^{t} \left< \nabla \Lambda(T - \theta, X(\theta)) , \text{d}W^{\gamma^*}(\theta) \right>, \quad 0 \leq t \leq T. \tag{5.16}
\]

Proof. The last thing we need to verify for the proof of Proposition 5.1, is that
\[
E_{\mathbb{P}^{\gamma^*}} \left[ \left| \overline{M}^{\gamma^*}, \overline{M}^{\gamma^*} \right|(T) \right] = E_{\mathbb{P}^{\gamma^*}} \left[ \int_{0}^{T} \left| \nabla \Lambda(T - t, X(t)) \right|^2 \text{d}t \right] < \infty. \tag{5.17}
\]
We observe that the expectation in (5.17) is equal to
\[
E_{\mathbb{P}^{\gamma^*}} \left[ \int_{0}^{T} \left| \nabla \Lambda(s, \overline{X}(s)) \right|^2 \text{d}s \right] = E_{\mathbb{P}} \left[ \int_{T}^{2T} \left| \nabla L(t, X(t)) \right|^2 \text{d}t \right]. \tag{5.18}
\]
This is because (3.1), (5.6) give \(\nabla \Lambda(s, \overline{X}(s)) = \nabla L(t, X(2T - t))\) with \(t = T + s \in [T, 2T]\); and because the \(\mathbb{P}^{\gamma^*}\)-distribution of \(X(2T - t) = \overline{X}(s)\) is the same as the \(\mathbb{P}\)-distribution of \(X(T + s) = X(t)\), on account of (4.29). But, as (4.18) holds for any finite time horizon \(T > 0\), the quantity in (5.18) is finite as well.

\[
\square
\]
5.3 Relative entropy dissipation

Exploiting the trajectorial evolution of the relative entropy process (5.13), provided by Proposition 5.1, allows us to derive some immediate consequences on the decrease of the relative entropy function \([0, T] \ni s \mapsto H(\mathcal{P}_s(s) \mid Q) \in (-\infty, \infty)\) and its rate of dissipation. The submartingale-property of the relative entropy process (5.13) shows once more, that this function is non-decreasing. More precisely, we have the following rate of change for the relative entropy.

**Corollary 5.2.** For all \(s, s_0 \geq 0\), we have

\[
H(\mathcal{P}_s(s) \mid Q) - H(\mathcal{P}_s(s_0) \mid Q) = -\frac{1}{2} \int_{s_0}^{s} I(\mathcal{P}_s(u) \mid Q) \, du.
\] (5.19)

**Proof.** Let \(s, s_0 \geq 0\) and choose \(T \geq \max\{s, s_0\}\). Taking expectations under \(P^{\gamma_*}\) in (5.14), and noting that the stochastic integral process in (5.16) is a martingale, leads to

\[
E_{P^{\gamma_*}}[\Lambda(s, X(s))] - E_{P^{\gamma_*}}[\Lambda(s_0, X(s_0))] = -\frac{1}{2} \int_{s_0}^{s} E_{P^{\gamma_*}}[|\nabla \Lambda(u, X(u))|^2] \, du.
\] (5.20)

Recalling the relative entropy (5.8) and the relative Fisher information (5.9), we obtain (5.19).

**Corollary 5.3.** For Lebesgue-almost every \(s \geq 0\), the rate of relative entropy dissipation equals

\[
\frac{d}{ds} H(\mathcal{P}_s(s) \mid Q) = -\frac{1}{2} I(\mathcal{P}_s(s) \mid Q).
\] (5.21)

6 From backwards dynamics “back” to forward dynamics

Starting with the forward Langevin–Smoluchowski dynamics (2.1), we have seen in Section 4 that the combined effects of time-reversal, and of stochastic control of the drift under an entropic-type criterion, lead to the backwards dynamics

\[
dX(s) = -\nabla \Psi(X(s)) \, ds + dW^\gamma_*(s), \quad 0 \leq s \leq T,
\] (6.1)

which are again of the Langevin–Smoluchowski type, but now viewed on the filtered probability space \((\Omega, \mathcal{G}, P^{\gamma_*})\). We will see now that this universal property of Langevin–Smoluchowski measure is consistent in the following sense: starting with the backwards Langevin–Smoluchowski dynamics of (6.1), after another reversal of time, the solution of a related stochastic control problem leads to the original forward Langevin–Smoluchowski dynamics (2.1) we started with. This consistency property should come as no surprise, but its formal proof requires the results of Section 5, which perhaps appeared artificial at first sight.

Let us recall from Subsection 5.1 that reversing time in (6.1) leads to the forward dynamics

\[
dX(t) = \left(\nabla \Lambda(T - t, X(t)) - \nabla \Psi(X(t))\right) \, dt + dW^\gamma_*(t), \quad 0 \leq t \leq T
\] (6.2)
on the filtered probability space \((\Omega, \mathcal{F}, P^{\gamma_*})\). By analogy with Section 4, we define an equivalent probability measure \(\Pi^\beta \sim P^{\gamma_*}\) as follows.

For any measurable process \([0, T] \times \Omega \ni (t, \omega) \mapsto \beta(t, \omega) \in \mathbb{R}^n\), adapted to the forward filtration \(\mathcal{F}\) of (2.14) and satisfying the condition

\[
P^{\gamma_*}\left[\int_0^T |\beta(t)|^2 \, dt < \infty\right] = 1,
\] (6.3)
we consider the exponential $(\mathbb{F}, \mathbb{P}^\gamma)$-local martingale
\[ Z^\beta(t) := \exp \left( \int_0^t \langle \beta(\theta), dW^\gamma(\theta) \rangle - \frac{1}{2} \int_0^t |\beta(\theta)|^2 d\theta \right), \quad 0 \leq t \leq T. \quad (6.4) \]

We denote by $\mathcal{B}$ the collection of all processes $\beta$ as above, for which $Z^\beta$ is a true $(\mathbb{F}, \mathbb{P}^\gamma)$-martingale.

Now, for every $\beta \in \mathcal{B}$, we introduce an equivalent probability measure $\Pi^\beta \sim \mathbb{P}^\gamma$ on path space, via
\[ \frac{d\Pi^\beta}{d\mathbb{P}^\gamma} \big|_{\mathcal{F}(t)} = Z^\beta(t), \quad 0 \leq t \leq T. \quad (6.5) \]

Then we deduce from the Girsanov theorem that, under the probability measure $\Pi^\beta$, the process
\[ W^\beta(t) := W^\gamma(t) - \int_0^t \beta(\theta) d\theta, \quad 0 \leq t \leq T \quad (6.6) \]
is $\mathbb{R}^n$-valued $\mathbb{F}$-Brownian motion, and the dynamics (6.2) become
\[ dX(t) = \left( \nabla \Lambda(T - t, X(t)) + \beta(t) - \nabla \Psi(X(t)) \right) dt + dW^\beta(t), \quad 0 \leq t \leq T. \quad (6.7) \]

We couple these dynamics with the stochastic differential (5.14) and deduce that the process
\[ N^\beta(t) := \Lambda(T - t, X(t)) + \frac{1}{2} \int_0^t |\beta(\theta)|^2 d\theta, \quad 0 \leq t \leq T \quad (6.8) \]
is a local $\Pi^\beta$-submartingale with decomposition
\[ dN^\beta(t) = \frac{1}{2} \left[ \nabla \Lambda(T - t, X(t)) + \beta(t) \right] dt + \left\langle \nabla \Lambda(T - t, X(t)), dW^\beta(t) \right\rangle. \quad (6.9) \]

In fact, introducing the sequence
\[ \tau_n := \inf \left\{ t \geq 0 : \int_0^t \left( |\nabla \Lambda(T - \theta, X(\theta))|^2 + |\beta(\theta)|^2 \right) d\theta \geq n \right\} \wedge T, \quad n \in \mathbb{N}_0 \quad (6.10) \]
of $\mathbb{F}$-stopping times with $\tau_n \uparrow T$, we see that the stopped process $N^\beta(\cdot \wedge \tau_n)$ is an $\mathbb{F}$-submartingale under $\Pi^\beta$, for every $n \in \mathbb{N}_0$. In particular, we observe
\[ H(P(2T) \mid Q) = H(\overline{\mathcal{F}}(T) \mid Q) = E_{\mathbb{P}^\gamma} \left[ \Lambda(T, \overline{X}(T)) \right] = E_{\Pi^\beta} \left[ \Lambda(T, X(0)) \right] \]
\[ \leq E_{\Pi^\beta} \left[ \Lambda(T - \tau_n, X(\tau_n)) + \frac{1}{2} \int_0^{\tau_n} |\beta(\theta)|^2 d\theta \right], \quad (6.11) \]
since $\Pi^\beta = \mathbb{P}^\gamma$ on $\mathcal{F}(0) = \sigma(X(0)) = \sigma(\overline{X}(T))$. Now (6.11) holds for every $n \in \mathbb{N}_0$, thus
\[ H(P(2T) \mid Q) \leq \liminf_{n \to \infty} E_{\Pi^\beta} \left[ \Lambda(T - \tau_n, X(\tau_n)) + \frac{1}{2} \int_0^{\tau_n} |\beta(\theta)|^2 d\theta \right]. \quad (6.12) \]

But the minimum in (5.7) is attained by $b_\ast = -\nabla \Lambda(s, x)$; likewise, the drift term in (6.9) vanishes, if we select the process $\beta_\ast \in \mathcal{B}$ via
\[ \beta_\ast(t, \omega) := -\nabla \Lambda(T - t, \omega(t)), \quad \text{thus} \quad \beta_\ast(t) = -\nabla \Lambda(T - t, X(t)), \quad 0 \leq t \leq T. \quad (6.13) \]

With this choice, the forward dynamics of (6.7) take the form
\[ dX(t) = -\nabla \Psi(X(t)) dt + dW^{\beta_\ast}(t); \quad (6.14) \]
that is, precisely the forward Langevin–Smoluchowski dynamics (2.1) we started with, but now with the “initial condition” \( X(0) = \overline{X}(T) \) and independent driving \( \mathbb{F} \)-Brownian motion \( W^{\beta_*} \), under \( \Pi^{\beta_*} \). Since \( \Pi^{\beta_*} = P^{\gamma_*} \) holds on the \( \sigma \)-algebra \( \mathcal{F}(0) = \sigma(X(0)) = \sigma(\overline{X}(T)) \), the initial distribution of \( X(0) \) under \( \Pi^{\beta_*} \) is equal to \( P(2T) \). Furthermore, with \( \beta = \beta_* \), the process of (6.8), (6.9) becomes a \( \Pi^{\beta_*} \)-local martingale, namely

\[
N^{\beta_*}(t) = \Lambda(T, X(0)) + \int_0^t \left\langle \nabla \Lambda(T - \theta, X(\theta)) , dW^{\beta_*}(\theta) \right\rangle, \quad 0 \leq t \leq T; \quad (6.15)
\]

and we have equality in (6.11), thus also

\[
H(P(2T) \mid Q) = \lim_{n \to \infty} E_{\Pi^{\beta_*}} \left[ \Lambda(T - \tau_n, X(\tau_n)) + \frac{1}{2} \int_0^{\tau_n} |\beta_*(\theta)|^2 d\theta \right]. \quad (6.16)
\]

We conclude that the infimum over \( \beta \in \mathcal{B} \) of the right-hand side in (6.12) is attained by the process \( \beta_* \) of (6.13), which gives rise to the Langevin–Smoluchowski dynamics (6.14) for the process \( (X(t))_{0 \leq t \leq T} \), under \( \Pi^{\beta_*} \). We formalize this result as follows.

**Theorem 6.1.** Consider the stochastic control problem of minimizing over the class \( \mathcal{B} \) of measurable, adapted processes \( \beta \) satisfying (6.3) and inducing an exponential martingale \( Z^{\beta} \) in (6.4), with the notation of (6.10) and with the forward dynamics of (6.7), the expected cost

\[
\mathcal{J}(\beta) := \lim_{n \to \infty} E_{\Pi^{\beta}} \left[ \Lambda(T - \tau_n, X(\tau_n)) + \frac{1}{2} \int_0^{\tau_n} |\beta(\theta)|^2 d\theta \right]. \quad (6.17)
\]

Under the assumptions of Section 2, the infimum \( \inf_{\beta \in \mathcal{B}} \mathcal{J}(\beta) \) is equal to the relative entropy \( H(P(2T) \mid Q) \) and is attained by the “score process” \( \beta_* \) of (6.13). This choice leads to the forward Langevin–Smoluchowski dynamics (6.14), and with \( \beta = \beta_* \) the limit in (6.17) exists as in (6.16).

**Proof.** We have to show that the minimizing process \( \beta_* \) belongs to the collection \( \mathcal{B} \) of admissible processes. By its definition in (6.13), the process \( \beta_* \) is measurable, and adapted to the forward filtration \( \mathbb{F} \) of (2.14). Thanks to (5.17) in Proposition 5.1, we have

\[
E_{P^{\gamma_*}} \left[ \int_0^T |\beta(t)|^2 dt \right] = E_{P^{\gamma_*}} \left[ \int_0^T \left| \nabla \Lambda(T - t, X(t)) \right|^2 dt \right] < \infty, \quad (6.18)
\]

which implies a fortiori that the condition in (6.3) is satisfied for \( \beta = \beta_* \).

It remains to check that the process \( Z^{\beta_*} \) defined in the manner of (6.4), is a true martingale. From Proposition 5.1 we have the stochastic differential

\[
d\Lambda(T - t, X(t)) = \frac{1}{2} \left| \nabla \Lambda(T - t, X(t)) \right|^2 dt + \left\langle \nabla \Lambda(T - t, X(t)) , dW^{\gamma_*}(t) \right\rangle, \quad (6.19)
\]

and therefore

\[
\int_0^t \left\langle \beta_*(\theta) , dW^{\gamma_*}(\theta) \right\rangle - \frac{1}{2} \int_0^t |\beta_*(\theta)|^2 d\theta \quad (6.20)
\]

\[
= - \int_0^t \left\langle \nabla \Lambda(T - \theta, X(\theta)) , dW^{\gamma_*}(\theta) \right\rangle - \frac{1}{2} \int_0^t \left| \nabla \Lambda(T - \theta, X(\theta)) \right|^2 d\theta \quad (6.21)
\]

\[
= \Lambda(T, X(0)) - \Lambda(T - t, X(t)) = \log \left( \frac{\lambda(T, X(0))}{\lambda(T - t, X(t))} \right), \quad (6.22)
\]
which expresses the exponential process of (6.4) with $\beta = \beta_s$ as

$$Z^{\beta_s}(t) = \frac{\lambda(T, X(0))}{\lambda(T - t, X(t))}, \quad 0 \leq t \leq T. \quad (6.23)$$

The process $Z^{\beta_s}$ is a positive local martingale, thus a supermartingale. To see that it is a true $(\mathcal{F}, \mathbb{P}^{\beta_s})$-martingale, it suffices to argue that it has constant expectation. But $Z^{\beta_s}(0) \equiv 1$, so we have to show $\mathbb{E}_P[Z^{\beta_s}(T)] = 1$. We denote again by $P(s, y; t, \xi)$ the transition kernel of the Langevin–Smoluchowski dynamics, note that

$$\mathbb{P}^{\beta_s}[X(s) \in dy, X(t) \in d\xi] = \bar{p}_s(s, y) P(s, y; t, \xi) dy d\xi \quad (6.24)$$

for $0 \leq s < t \leq T$ and $(y, \xi) \in \mathbb{R}^n \times \mathbb{R}^n$, and recall the invariance property (4.24) of $Q$, to deduce $\mathbb{E}_P[Z^{\beta_s}(T)] = 1$ in the manner of (4.25) – (4.28). This implies that $Z^{\beta_s}$ is a true martingale and completes the proof of Theorem 6.1. \hfill \Box

### 6.1 Entropic interpretation of the expected cost

By analogy with Subsection 4.1, we interpret now the expected cost on the right-hand side of (6.17) in terms of relative entropies. From (6.4) – (6.6), we deduce that

$$\log \left( \frac{d\Pi^\beta}{d\mathbb{P}^{\gamma_s}}_{\mathcal{F}(\tau_n)} \right) = \int_0^{\tau_n} \langle \beta(\theta), dW^\beta(\theta) \rangle + \frac{1}{2} \int_0^{\tau_n} |\beta(\theta)|^2 d\theta \quad (6.25)$$

holds for every $\beta \in \mathcal{B}$ and $n \in \mathbb{N}_0$. Therefore, as the $\Pi^\beta$-expectation of the stochastic integral in (6.25) vanishes, the expected quadratic cost, or “energy”, term in (6.17) is equal to the relative entropy

$$\mathbb{E}_{\Pi^\beta} \left[ \frac{1}{2} \int_0^{\tau_n} |\beta(\theta)|^2 d\theta \right] = \mathbb{E}_{\Pi^\beta} \left[ \log \left( \frac{d\Pi^\beta}{d\mathbb{P}^{\gamma_s}}_{\mathcal{F}(\tau_n)} \right) \right] \quad (6.26)$$

In order to interpret the first term in (6.17), we assume that $Q$, and thus also the induced measure $Q$ on path space, are probability measures. Then we have

$$\mathbb{E}_{\Pi^\beta} [\Lambda(T - \tau_n, X(\tau_n))] = \mathbb{E}_{\Pi^\beta} \left[ \log \left( \frac{d\Pi^{\gamma_s}}{dQ}_{\sigma(X(\tau_n))} \right) \right] \quad (6.27)$$

$$= \mathbb{E}_{\Pi^\beta} \left[ \log \left( \frac{d\Pi^\beta}{dQ}_{\sigma(X(\tau_n))} \right) \right] - \mathbb{E}_{\Pi^\beta} \left[ \log \left( \frac{d\Pi^\beta}{d\mathbb{P}^{\gamma_s}}_{\sigma(X(\tau_n))} \right) \right]. \quad (6.28)$$

We conclude that, in this case, the expected cost of (6.17) is equal to the sum $H_n^\beta + D_n^\beta$ of two non-negative quantities:

$$H_n^\beta := \mathbb{E}_{\Pi^\beta} \left[ \log \left( \frac{d\Pi^\beta}{dQ}_{\sigma(X(\tau_n))} \right) \right], \quad (6.29)$$

the relative entropy of the probability measure $\Pi^\beta$ with respect to the probability measure $Q$ when both are restricted to the $\sigma$-algebra generated by the random variable $X(\tau_n)$; and

$$D_n^\beta := \mathbb{E}_{\Pi^\beta} \left[ \log \left( \frac{d\Pi^\beta}{d\mathbb{P}^{\gamma_s}}_{\mathcal{F}(\tau_n)} \right) \right] - \mathbb{E}_{\Pi^\beta} \left[ \log \left( \frac{d\Pi^\beta}{d\mathbb{P}^{\gamma_s}}_{\sigma(X(\tau_n))} \right) \right], \quad (6.30)$$

the difference between the relative entropies of the probability measure $\Pi^\beta$ with respect to the probability measure $\mathbb{P}^{\gamma_s}$, when restricted to the $\sigma$-algebra generated by the collection of random variables $(X(\theta \wedge \tau_n))_{0 \leq \theta \leq T}$ and by the random variable $X(\tau_n)$, respectively.
6.2 Conclusion

When the invariant (Gibbs) measure $Q$ is finite, the procedures of Sections 4 and 6 — combining time-reversal with stochastic control of the drift — lead to an alternating series of forward and backward Langevin–Smoluchowski dynamics, with initial distributions starting at $P(0)$ and converging along $(P(kT))_{k \in \mathbb{N}_0}$ to the invariant (probability) measure $Q$. Whereas, the values of the corresponding stochastic control problems decrease along $(H(P(kT) \mid Q))_{k \in \mathbb{N}}$ to zero.
