Tolerance Modelling of Vibrations of a Sandwich Plate with Honeycomb Core

Jakub Marczak

Department of Structural Mechanics, Łódź University of Technology, 90-924 Łódź, Poland; jakub.marczak@p.lodz.pl

Abstract: Sandwich structures are commonly used in many branches of modern engineering, such as aerospace or naval constructions. In this work, a vibration analysis of such structures is performed with the use of an analytical model based on a zig-zag hypothesis. Due to the assumed periodic microstructure, which may occur in any layer of the structure, the initial governing equations describing its dynamic behaviour may contain periodic, non-continuous coefficients. The main aim of the presented paper is to show an analytical solution to the issue of the vibration analysis of the mentioned structures. With the use of the tolerance averaging technique, the initial governing equations are transformed to the form with constant coefficients, which is convenient to solve using well-known mathematical methods. The derived model is a versatile solution for any type of periodically inhomogeneous sandwich plate, including sandwich plates with a honeycomb core. Eventually, in the calculation example, the application of the derived averaged model in the analysis of vibrations of such structures is presented and discussed. The convergence of results of the tolerance model and FEM analysis proves the correctness and superiority of the proposed solution.

Keywords: sandwich plate; vibrations; honeycomb core; tolerance modelling; periodic microstructure

1. Introduction

Sandwich structures are a specific group of composites, which usually consist of at least three layers. Two outer layers, so called faces, are characterised by high mechanical properties, while an inner layer, the so called core, can be specially formed to produce a higher stiffness of the whole structure, desired thermal or acoustic insulation or heat resistance. Due to their exceptional strength-to-weight ratio, they are commonly used in aerospace, naval or even civil engineering.

Even though their properties have been known for decades, there are still many groups of researchers who investigate such structures. Let us mention several interesting recent papers, such as static analysis of sandwich structure with corrugated core Tewari et al. [1], multi-scale static analysis of sandwich composites [2], the analysis of dynamic response of sandwich structures to various impacts [3–7] or the attempt of creating the easy-to-repair core [8]. Among those papers, one can find a significant number of works, which are focused on an experimental examination of certain properties of the composite. The importance of such works is unquestionable. However, the preparation of a specific experiment is always a time-consuming and costly process, which does not necessarily have to end up with reliable results. This is why the ability to create computational models of the considered structures is vitally important.

There are many methods of modelling sandwich structures. Among the analytical approaches one can distinguish classic plate theory, broken line hypothesis (zigzag theory), refined zigzag theory, sinusoidal shear deformation theory, first-order shear deformation theory or higher-order shear deformation theory. The differences between each of those theories are widely described in the literature, cf. [9–12], while their applications can be found, for example, in [13–15]. The mentioned analytical models of sandwich structures usually
produce precise results only if the layers of the considered structure are homogeneous. Meanwhile, the cores of the sandwich structures are often designed as laminates, composites or even corrugated and lattice-type structures. In such cases, the most common and versatile method of analysis is the finite element method. The application of this method can be found, for example, in [16–21]. However, it should be mentioned that creating and evaluating numerical models of sandwich plates with complicated heterogeneous cores is a time-consuming process, which additionally requires a lot of computing resources.

In this paper, an issue of dynamics of a specific type of sandwich plate with a hexagonal honeycomb core is investigated, cf. Figure 1. Due to the complicated form of the core, the most common approach to modelling such structures is the evaluation of effective properties of the inner layer, cf. [22–24]. Such an approach can be considered an effective method for obtaining the general overall performance of the considered structure. However, it neglects local fluctuations of stress and strains, which occur within the faces due to the heterogeneous core. In this paper, the analytical model, which takes into consideration the mentioned fluctuations, is presented and validated. Basing the broken line hypothesis on displacements, the initial governing equations of the three-layered sandwich structure are derived. Due to the heterogeneous core, their coefficients are a periodic, non-continuous and highly-oscillating function of the spatial coordinates. In order to overcome the difficulties in solving such system of partial differential equations, the tolerance averaging technique is used. With its concepts, it is possible to transform the initial system of partial differential equations with periodic coefficients into the form with constant coefficients, cf. [25]. Within the literature, one can find multiple applications of this technique in various mechanical issues, such as stability analysis [26–29], dynamics [30–33] or even heat conduction issues [34–37].

2. Modelling Foundations

Let us denote $Ox_1x_2x_3$ as an orthogonal Cartesian coordinate system, where $x \equiv (x_1, x_2)$, and $t$ as a time coordinate. The considered three-layered plate is assumed to be rectangular and to have spans $L_1$ and $L_2$, along $x_1$- and $x_2$-axis directions, respectively. As a result, the mid-plane of the core of the structure can be denoted $\Pi = [0, L_1] \times [0, L_2]$. Moreover, the considered structure is assumed to be symmetric toward the mentioned mid-plane; hence, for the specific $x$ coordinate, both outer layers have the same material properties and thicknesses. Eventually, let us introduce $h_c(x)$ as the thickness of the core, $h_f(x)$ as a thickness of the outer layers and $H(x) = h_c(x) + 2h_f(x)$ as a total thickness of the sandwich plate, so it is possible to denote the whole region occupied by the undeformed structure as: $\Omega \equiv \{(x, x_3) : -H(x)/2 \leq x_3 \leq H(x)/2, x \in \Pi\}$, cf. Figure 2.
At this stage of investigations, let us assume that every layer of the sandwich plate can be characterised by a specific periodic microstructure. It means that all material properties and thicknesses of every layer can be a periodic function of spatial coordinate \( x \equiv (x_1, x_2) \). Based on this assumption, it is possible to distinguish a small repeatable element called periodicity cell \( \Delta \). The periodicity cell can be given by any shape. In the easiest 2D case, it is defined as a rectangle, in which the dimensions along the \( x_1 \) - and \( x_2 \)-axis directions are defined as \( l_1 \) and \( l_2 \), respectively.

Eventually, for the sake of simplicity, let us assume that the whole structure is made of isotropic materials. Consequently, let us denote \( E_f(x), \nu_f(x), G_f(x), \rho_f(x) \) as modulus of elasticity, Poisson ratio, shear modulus and mass density of the faces, and \( E_c(x), \nu_c(x), G_c(x), \rho_c(x) \) as modulus of elasticity, Poisson ratio, shear modulus and mass density of the core.

### 3. Derivation of Initial Governing Equations

In this section, the initial governing equations describing the dynamic behaviour of the already described structure are derived and discussed. In all subsequent equations, the spatial derivative is denoted \( \partial_i \equiv \frac{\partial}{\partial x_i}, i = 1, 2, 3 \), while a time derivative is denoted with an overdot.

Let us start with the formulation of the in-plane deformation hypothesis for the considered plate. In this paper, the broken line hypothesis (or the zigzag hypothesis) is applied to the analysis of vibrations. According to this, the displacements along each spatial coordinate \( (x_1, x_2, x_3) \) are defined with specific linear piecewise functions as follows:

\[
\begin{align*}
u_1(x, x_3, t) &= \begin{cases} -x_3 \partial_1 w(x, t) - h_c \psi_1(x, t) & \frac{-H}{2} \leq x_3 < -\frac{h_c}{2}, \\ -x_3 \partial_1 w(x, t) + 2x_3 \psi_1(x, t) & \frac{-h_c}{2} \leq x_3 \leq \frac{h_c}{2}, \\ -x_3 \partial_1 w(x, t) + h_c \psi_1(x, t) & \frac{h_c}{2} < x_3 \leq \frac{H}{2}, \end{cases} \\
u_2(x, x_3, t) &= \begin{cases} -x_3 \partial_2 w(x, t) - h_c \psi_2(x, t) & \frac{-H}{2} \leq x_3 < -\frac{h_c}{2}, \\ -x_3 \partial_2 w(x, t) + 2x_3 \psi_2(x, t) & \frac{-h_c}{2} \leq x_3 \leq \frac{h_c}{2}, \\ -x_3 \partial_2 w(x, t) + h_c \psi_2(x, t) & \frac{h_c}{2} < x_3 \leq \frac{H}{2}, \end{cases} \\
u_3(x, x_3, t) &= w(x, t), \end{align*}
\]
where $w(x, t)$ is a function of vertical displacements of the mid-plane of the structure $Π$, while $ψ_1(x, t), ψ_2(x, t)$ are certain dimensionless functions representing variations of in-plane displacements caused by three-layered structure. The physical sense of those functions is shown in Figure 3.

![Figure 3. In-plane displacement hypothesis according to the broken line hypothesis.](image)

The deformation hypothesis should be followed by a small deformation assumption:

$$ε_{ij} = \frac{1}{2} \left( \partial_j u_i + \partial_i u_j \right), \quad i, j = 1, 2, 3,$$

and a stress-strain relation. In our case, a typical Hooke’s law for plates made of isotropic materials is used, so:

$$σ_{αβ} = \tilde{C}_{αβγδ} ε_{γδ}, \quad α, β, γ, δ = 1, 2,$$

where the only non-zero terms are:

\[\tilde{C}_{1111} = \tilde{C}_{2222} = \frac{E(x, x_3)}{1 - [ν(x, x_3)]^2},\]
\[\tilde{C}_{1122} = \tilde{C}_{2211} = \frac{E(x, x_3) · ν(x, x_3)}{1 - [ν(x, x_3)]^2},\]
\[\tilde{C}_{1212} = \tilde{C}_{2121} = \tilde{C}_{2112} = \tilde{C}_{1221} = G(x, x_3) = \frac{E(x, x_3)}{2[1 + ν(x, x_3)]},\]

and:

$$E(x, x_3) = \begin{cases} E_f(x) & \text{for } -H/2 ≤ x_3 < -h_c/2 \\ E_c(x) & \text{for } -h_c/2 ≤ x_3 ≤ h_c/2 \\ E_f(x) & \text{for } h_c/2 < x_3 ≤ H/2 \end{cases},$$

$$ν(x, x_3) = \begin{cases} ν_f(x) & \text{for } -H/2 ≤ x_3 < -h_c/2 \\ ν_c(x) & \text{for } -h_c/2 ≤ x_3 ≤ h_c/2 \\ ν_f(x) & \text{for } h_c/2 < x_3 ≤ H/2 \end{cases}.$$

Eventually, one should formulate the equations of equilibrium, which, for the small part of the considered plate, can be written as:

$$\partial_α β M_{αβ} + q = μ \bar{u}_3 + \partial_α \bar{μ}_α, \quad \partial_α M_{αβ} - Q_α + m_α = \bar{μ}_α, \quad α, β = 1, 2,$$
where:

\[ M_{ab}(x, t) = \int_{H(x)} c_{ab}(x, x_3, t)dx_3, \quad Q_a(x, t) = \int_{H(x)} c_{a3}(x, x_3, t)dx_3, \]

\[ \mu(x) = \int_{H(x)} \rho(x, x_3)dx_3, \quad \mu_a(x, t) = \int_{H(x)} \rho(x, x_3)\mu_a(x, x_3, t)dx_3, \]

\[ q(x, t) = c_{33}(x, x_3, t)|H(x)/2 + \mu_a m_a(x, t), \quad m_a(x, t) = c_{a3}(x, x_3, t)x_3|H(x)/2. \]

As a result of all the presented relations, it is possible to derive a set of initial governing equations of the three-layered sandwich plate, which can be presented in a simplified form as:

\[ \partial_{x}^{i} \left[ C_{\alpha \beta \gamma \delta} \partial_{x}^{j} \psi(x, t) - \dot{C}_{\alpha \beta \gamma \delta} \partial_{x}^{j} \psi^{\prime}(x, t) \right] - A_{11}(\rho_{f}, \rho_{c}) \partial_{x} \ddot{w}(x, t) + A_{12}(\rho_{f}, \rho_{c}) \partial_{x} \ddot{w}(x, t) = q(x, t)/h^{3}, \]

\[ \partial_{x}^{i} \left[ C_{\alpha \beta \gamma \delta} \partial_{x}^{j} \psi(x, t) - \dot{C}_{\alpha \beta \gamma \delta} \partial_{x}^{j} \psi^{\prime}(x, t) \right] - A_{11}(\rho_{f}, \rho_{c}) \partial_{x} \ddot{w}(x, t) + A_{12}(\rho_{f}, \rho_{c}) \partial_{x} \ddot{w}(x, t) = m_{\delta}(x, t)/h^{3}, \]

\[ \alpha, \beta, \gamma, \delta = 1, 2, \]

where:

\[ a_{1} = \left( \frac{2}{3} X^{2} + X + \frac{1}{3} \right) X, \quad a_{2} = X^{2} + X, \quad X = \frac{h(t)}{h_{t}(x)}, \]

\[ A_{11}(Y, Z) = Y \cdot a_{1} + \frac{1}{2} \cdot Z, \quad A_{12}(Y, Z) = Y \cdot a_{2} + \frac{1}{2} \cdot Z, \]

\[ B_{1} = \frac{2 \rho_{f}(x) - h_{e}(x) + \rho_{c}(x) - h_{e}(x)}{h_{e}(x)}, \quad B_{2} = \frac{2 \rho_{f}(x)}{h_{e}(x)}, \]

\[ C_{1111} = C_{2222} = A_{11} \left( \frac{E_{f}(x)}{1 - [v_{f}(x)]^{2}} \right), \quad \dot{C}_{1111} = \dot{C}_{2222} = A_{12} \left( \frac{E_{f}(x)}{1 - [v_{f}(x)]^{2}} \right), \]

\[ C_{1212} = C_{2121} = C_{21211} = A_{11} \left( G_{f}(x), G_{c}(x) \right), \quad \dot{C}_{1212} = \dot{C}_{2121} = \dot{C}_{21211} = A_{12} \left( G_{f}(x), G_{c}(x) \right), \]

\[ C_{1122} = C_{2211} = A_{11} \left( E_{f}(x)\nu_{f}(x) / [1 - [v_{f}(x)]^{2}], E_{c}(x)\nu_{c}(x) / [1 - [v_{c}(x)]^{2}] \right), \quad \dot{C}_{1122} = \dot{C}_{2211} = A_{12} \left( E_{f}(x)\nu_{f}(x) / [1 - [v_{f}(x)]^{2}], E_{c}(x)\nu_{c}(x) / [1 - [v_{c}(x)]^{2}] \right). \]

Equations (2), together with the subsequent denotations (3), constitute the initial analytical model of dynamic behaviour of the three-layered sandwich plate based on the broken line hypothesis. Based on the definitions (3) it can be observed that in the case of structure with a certain type of periodic inhomogeneity, the system of Equations (2) is characterised by periodic, non-continuous and highly oscillating coefficients, which makes it very difficult to solve. In the next step of investigations, the tolerance averaging technique is applied to transform the obtained system of equations into the form with constant coefficients.

4. Basics of Tolerance Averaging Technique

In this section, only the main concepts of the tolerance averaging technique are presented. For the detailed description of the used technique, one should refer to the literature, for example, [25].

Let us start with a definition of a tolerance parameter \( \delta \), which is an arbitrary positive number. In the whole modelling process it is assumed that certain terms with a difference smaller than the tolerance parameter \( \delta \) can be treated as equals.

Let us distinguish two points from the mid-plane of the considered structure as \( x = (x_1, x_2) \) and \( x' = (x'_1, x'_2) \). The specific periodicity cell \( \Delta \) with a centre at \( x \) is denoted as \( \Delta(x) = x + \Delta \), where, in the case of a rectangular periodicity cell \( \Delta = [-l_{1}/2, l_{1}/2] \times [-l_{2}/2, l_{2}/2] \), the close surroundings of such a cell are defined as \( \Pi(x) = \Pi \cap \bigcup_{x' \in \Delta(x)} \Delta(x') \).
\( x \in \mathcal{I}, \) where \( \mathcal{I} = \bigcup_{x' \in \Delta(x)} \Delta(x'), \) \( x \in \Pi. \) Keeping in mind those denotations, it is possible to define different types of functions, such as tolerance periodic function, slowly varying function, highly oscillating function and fluctuation shape function, which are crucial for the tolerance averaging technique.

Let \( H^2(\Pi) \) be a Sobolev space, \( \partial^k f \) be the \( k \)th gradient of function \( f = f(x), x \in \Pi, \) \( k = 0, 1, 2, \ldots, n, \) where \( \partial^0 f = f. \)

Function \( f \in H^2(\Pi) \) is called the tolerance periodic function with respect to cell \( \Delta \) and tolerance parameter \( \delta, f \in TP^k_\delta(\Delta), \) if the following conditions are held:

\[
\begin{align*}
&\forall x \in \Pi \left[ \exists \tilde{f}^{(k)}(x, \cdot) \in H^0(\Delta) \right] \left[ \left\| \partial^k f \big|_{\Pi_x} - \tilde{f}^{(k)}(x, \cdot) \right\|_{H^0(\Pi_x)} \leq \delta \right], \\
&\int_{\Delta(x)} \tilde{f}^{(k)}(\cdot, z) dz \in C^0(\Pi).
\end{align*}
\]

Function \( \tilde{f}^{(k)}(x, \cdot) \) is referred to as the periodic approximation of \( \partial^k f \) in \( \Delta(x), x \in \Pi. \)

Function \( v \in H^2(\Pi) \) is called the slowly varying function with respect to cell \( \Delta \) and tolerance parameter \( \delta, v \in SV^k_\delta(\Delta), \) if the following conditions are held:

\[
\begin{align*}
&\forall x \in \Pi \left[ \exists \bar{v}^{(k)}(x, \cdot) \in H^0(\Delta) \right] \left[ \partial^k v(x, \cdot) = \bar{v}^{(k)}(x, \cdot) \right], \\
&\partial^k \bar{v} \in C^0(\Pi).
\end{align*}
\]

Function \( h \in H^2(\Pi) \) is called the highly oscillating function with respect to cell \( \Delta \) and tolerance parameter \( \delta, h \in HO^k_\delta(\Delta), \) if the following conditions are held:

\[
\begin{align*}
&\forall x \in \Pi \left[ \exists \tilde{h}^{(k)}(x, \cdot) \in H^0(\Delta) \right] \left[ \partial^k h(x, \cdot) = \tilde{h}^{(k)}(x, \cdot) \right], \\
&\forall x \in \Pi \left[ \Delta(x) \subseteq \Pi \right] \left[ \langle \bar{h}(x) \rangle = 0 \right],
\end{align*}
\]

where \( \bar{h} \) is a certain periodic and positive function.

There are several original concepts used in the tolerance modelling procedure. One of them is the concept of an averaging operator, which for a 2D issue can be presented in the form:

\[
\langle \partial^k f \rangle(x) = \frac{1}{\Delta(x)} \int_{\Delta(x)} \tilde{f}^{(k)}(x, y) dy, \quad k = 0, 1, 2, \ldots, n, \quad x \in \mathcal{I}.
\]

Another concept is called a micro–macro decomposition of a certain physical field. According to its certain field, \( u(\cdot, t) \) can be expressed as a sum of an averaged macro-field \( U(\cdot, t) \) of a certain physical property, \( U(\cdot, t) \in SV^k_\delta(\Delta), \) and products of arbitrarily chosen fluctuation shape functions \( h^A(\cdot), h^A(\cdot) \in FS^k_\delta(\Delta), \) and unknown functions of fluctuation amplitudes \( V^A(\cdot, t), V^A(\cdot, t) \in SV^k_\delta(\Delta): \)

\[
u(u, t) = U(\cdot, t) + h^A(\cdot)V^A(\cdot, t), \quad A = 1, 2, \ldots, n.
\]

Eventually, based on all of the aforementioned concepts, a set of tolerance averaging approximations can be formulated. Exemplary transformations are presented below:
\[
\langle \phi \rangle (\cdot) = \langle \hat{\phi} \rangle (\cdot) + O(\delta),
\]
\[
\langle \phi F \rangle (\cdot) = \langle \phi \rangle (\cdot) F(\cdot) + O(\delta),
\]
\[
\langle \phi g^k (gF) \rangle (\cdot) = \langle \phi \partial g^k \rangle (\cdot) F(\cdot) + O(\delta),
\]
\[
\langle g \partial^k (\phi \Phi) \rangle (\cdot) = -\langle \phi \partial^k g \rangle (\cdot) + O(\delta),
\]
\[k = 1, 2, \ldots, n, \quad 0 < \delta \ll 1,
\]
\[
\phi, \Phi \in TP^k_\delta(\Delta), \quad F \in SV^k_\delta(\Delta), \quad g \in FS^k_\delta(\Delta),
\]
where \(O(\delta)\) is a negligibly small term.

5. Governing Equations of the Tolerance Model

In this section, a general procedure for deriving a tolerance model of vibrations of a micro-heterogeneous three-layered sandwich plate is presented and discussed.

Let us start with the initial system of governing Equations (2). As was already mentioned, in the case of a structure with specific periodic inhomogeneities, the system of Equations (2) is characterised by periodic, non-continuous coefficients. The presented tolerance modelling procedure makes it possible to transform it to a system of differential equations with constant coefficients.

At the beginning of the transformations, the whole considered structure is divided into a number of small, repeatable elements, called periodicity cells \(\Delta\). The system of governing equations remains true for any basic periodicity cell. In the next step, the micro-macro decomposition of all displacement fields present in (2) is required. Basing on definition (5), let us formulate it as follows:

\[
w(x, t) = W(x, t) + g^A(x)Q^A(x, t),
\]
\[
\psi_\alpha(x, t) = \Theta_\alpha(x, t) + h^B_\alpha(x)\Phi^B_\alpha(x, t),
\]
\[\alpha = 1, 2, A = 1, 2, \ldots, N, \quad B = 1, 2, \ldots, M,
\]
where \(W(x, t) \in SV^k_\delta, \Theta_\alpha(x, t) \in SV^k_\delta\) are vertical and in-plane macrodisplacements, respectively, \(g^A(x) \in FS^k_\delta(\Delta), h^B_\alpha(x) \in FS^k_\delta(\Delta)\) are vertical and in-plane fluctuation shape functions and \(Q^A(x, t) \in SV^k_\delta, \Phi^B_\alpha(x, t) \in SV^k_\delta\) are amplitudes of those fluctuations. Then, the averaging operator (4) should be applied to the derived system of equations and the orthogonalisation condition of those equations and an arbitrarily chosen set of fluctuation shape functions should be formulated. Eventually, a series of tolerance averaging approximations (6) should be applied, so the most convenient form of governing equations is obtained.

As a result of all the aforementioned transformations, the tolerance model of vibrations of three-layered periodic sandwich plate can be written in the following form:
\[
\langle C_\alpha \hat{\gamma} \rangle \partial_\alpha \hat{\gamma} W + \langle C_\beta \hat{\gamma} \partial_\beta \hat{\gamma} \partial_\gamma \hat{\gamma}^A \rangle Q^A - \langle C_\gamma \hat{\gamma} \partial_\alpha \hat{\gamma} \partial_\beta \hat{\gamma} \rangle - \langle C_\Sigma^\gamma \partial_\alpha \hat{\gamma} \partial_\beta \hat{\gamma} \partial_\gamma \hat{\gamma} \rangle \Phi_\delta + \\
- \langle A_{11}(\rho_f, \rho_c) \rangle \partial_{\alpha\alpha} W - \langle A_{11}(\rho_f, \rho_c) \partial_{\alpha\alpha} \hat{\gamma}^A \rangle Q^A + \langle A_{12}(\rho_f, \rho_c) \rangle \partial_\alpha \Theta_\delta + \\
+ \langle A_{12}(\rho_f, \rho_c) \partial_\alpha h^\delta_\beta \rangle \Phi_\delta + \langle B_1 \rangle W = \left( q / h^3 \right)_\delta, \\
\langle C_\alpha \hat{\gamma} \rangle \partial_\alpha \hat{\gamma} W + \langle C_\beta \hat{\gamma} \partial_\beta \hat{\gamma} \partial_\gamma \hat{\gamma}^A \rangle Q^A - \langle C_\gamma \hat{\gamma} \partial_\alpha \hat{\gamma} \partial_\beta \hat{\gamma} \rangle \partial_{\alpha\alpha} W - \langle A_{11}(\rho_f, \rho_c) \partial_{\alpha\alpha} \hat{\gamma}^A \rangle Q^A + \\
+ \langle A_{12}(\rho_f, \rho_c) \partial_\alpha h^\delta_\beta \rangle \partial_\alpha \Theta_\delta + \\
- \langle C_\beta \hat{\gamma} \partial_\beta h^\delta_\gamma \rangle \Phi_\delta - \langle A_{11}(\rho_f, \rho_c) \partial_{\alpha\alpha} h^\delta_\gamma \rangle \Phi_\delta + \langle B_1 \rangle Q^A = \left( q_\delta^K / h^2 \right)_\delta, \\
\langle C_\alpha \hat{\gamma} \partial_\alpha \hat{\gamma} h^\delta_\gamma \rangle \partial_{\alpha\alpha} W + \langle C_\beta \hat{\gamma} \partial_\beta \hat{\gamma} \partial_\gamma \hat{\gamma}^A \rangle Q^A - \langle C_\gamma \hat{\gamma} \partial_\alpha \hat{\gamma} \partial_\beta \hat{\gamma} \rangle \partial_{\alpha\alpha} W - \langle A_{11}(\rho_f, \rho_c) \partial_{\alpha\alpha} \hat{\gamma}^A \rangle Q^A + \\
+ \langle A_{12}(\rho_f, \rho_c) \partial_\alpha h^\delta_\beta \rangle \partial_\alpha \Theta_\delta + \\
- \langle C_\beta \hat{\gamma} \partial_\beta h^\delta_\gamma \rangle \Phi_\delta - \langle A_{11}(\rho_f, \rho_c) \partial_{\alpha\alpha} h^\delta_\gamma \rangle \Phi_\delta + \langle B_1 \rangle \Phi_\delta = \left( m_\delta / h^2 \right)_\delta, \\
\langle B_1 Q^A \rangle = 0, \quad \langle B_2 h^\delta_\alpha \rangle = 0, \quad a, \beta, \gamma, \delta = 1, 2, \quad A, K = 1, 2, \ldots, N, \quad B, L = 1, 2, \ldots, M,
\]

where in Equations (8) there is no summation over \( \delta \). The above system of equations is a system of \( 3 + N + M \) equations with constant coefficients, which can be solved using well-known mathematic methods. The greatest advantage of the presented solution is that the same model can be theoretically used to analyse any type of microheterogeneous sandwich plate, which can be useful during the optimisation process.

6. Free Vibration Analysis of Sandwich Plate with Honeycomb Core

In this section, free vibration frequencies of a three-layered sandwich plate with honeycomb core are evaluated using the derived tolerance model (8) and validated with the use of FEM analysis.

The considered structure is a three-layered sandwich plate simply supported on all four edges. Let us assume that its characteristic dimensions along the \( x_1 \) and \( x_2 \) axis directions are equal to \( L_1 \) and \( L_2 \), respectively. The thickness of every layer is constant throughout the structure and equal to \( h_f(x) = h_f \) and \( h_c(x) = h_c \), hence \( H(x) = 2h_f + h_c = H \). Additionally, it is assumed that every layer is made of isotropic materials only. Additionally, it should be emphasised that the structure consists of homogeneous outer layers and a core with a periodic honeycomb microstructure, cf. Figure 1. The details of the basic periodicity cell defined by the core microstructure, together with a physical sense of the introduced denotations used to describe it, are presented in Figure 4.

It can be easily noticed that the investigated structure fulfills all initial conditions of the derived averaged model. Hence, it can be used in its vibration analysis. In order to obtain free vibration frequencies of the described structure, all external loadings in (8) must be neglected. In the second step, a set of fluctuation shape functions must be assumed. The main aim of introducing such functions is the modelling of microscale disturbances in displacement fields caused by periodic microstructure, hence those functions should be properly adjusted. The most accurate way of obtaining them is solving the eigenvalue issue on the basic periodicity cell with, for example, the FEM analysis. However, the application of those exact functions, derived specially for a specific periodicity cell, is usually inconvenient in a large scale optimisation process. That is why, in this work, an approximation of those functions is introduced in the following form:
\[ g^1(x) = \begin{cases} \frac{1}{2} \left[ \cos \left( \frac{\pi}{2} \sqrt{x_1^2 + x_2^2} \right) + 1 \right] & \text{for } x_1^2 + x_2^2 \leq Z^2 \\ \frac{1}{2} \left[ \cos \left( \frac{\pi}{2} \sqrt{\left( x_1 - \frac{x_3}{\sqrt{2}} R \right)^2 + \left( x_2 - \frac{x_3}{\sqrt{2}} R \right)^2} \right) + 1 \right] & \text{for } \left( x_1 - \frac{x_3}{\sqrt{2}} R \right)^2 + \left( x_2 - \frac{x_3}{\sqrt{2}} R \right)^2 \leq Z^2 \\ \frac{1}{2} \left[ \cos \left( \frac{\pi}{2} \sqrt{\left( x_1 + \frac{x_3}{\sqrt{2}} R \right)^2 + \left( x_2 + \frac{x_3}{\sqrt{2}} R \right)^2} \right) + 1 \right] & \text{for } \left( x_1 + \frac{x_3}{\sqrt{2}} R \right)^2 + \left( x_2 + \frac{x_3}{\sqrt{2}} R \right)^2 \leq Z^2 \\ 0 & \text{otherwise} \end{cases} \]

The visualisation of the proposed fluctuation shape functions is presented in Figure 5. It can be noticed that the normalising conditions \( \langle B_1 g^1 \rangle = 0, \langle B_2 h_a^1 \rangle = 0 \) are instantly satisfied by those functions.

Apart from fluctuation shape functions, one should also assume the form of a solution of unknown displacement fields. In case of plate, which is simply supported on all four edges, it is possible to predict this form in a way that satisfies all the boundary conditions:

\[
\begin{align*}
W(x, t) &= A_W \sin(n\pi x_1 / L_1) \sin(m\pi x_2 / L_2) \sin(\omega t), \\
\Theta_1(x, t) &= A_{\Theta_1} \cos(n\pi x_1 / L_1) \sin(m\pi x_2 / L_2) \sin(\omega t), \\
\Theta_2(x, t) &= A_{\Theta_2} \sin(n\pi x_1 / L_1) \cos(m\pi x_2 / L_2) \sin(\omega t), \\
Q^1(x, t) &= A_Q \sin(n\pi x_1 / L_1) \sin(m\pi x_2 / L_2) \sin(\omega t), \\
\Phi^a(x, t) &= A_{\Phi^a} \sin(n\pi x_1 / L_1) \sin(m\pi x_2 / L_2) \sin(\omega t), \quad a = 1, 2,
\end{align*}
\]

where \( A_W, A_{\Theta_1}, A_{\Theta_2}, A_Q, A_{\Phi^a} \) are unknown amplitudes of vibrations, \( n, m \) are wave numbers and \( \omega \) is a free vibration angular frequency. By introducing definitions (10) to the system of Equations (8), one obtains a simple set of six algebraic equations, which properly transformed yield-free vibration frequencies of the considered structure. Due to
recent reports, that taking into considerations fluctuations of both in-plane and vertical
displacements may lead to imprecise results, cf. [38], in our investigations, two different
cases of tolerance model are considered. In Case I it is assumed that in-plane fluctuations
have negligibly small amplitudes, hence, they can be neglected:
\[ g_1(x) \equiv \tilde{g}_1(x), \quad h_{11} \equiv 0, \quad h_{12} \equiv 0, \]
while in Case II the vertical fluctuations are negligibly small when compared to in-plane
fluctuations:
\[ g_1(x) \equiv 0, \quad \tilde{h}_{11}(x) \equiv \tilde{h}_1(x), \quad \tilde{h}_{12}(x) \equiv \tilde{h}_2(x). \]

Consequently, the algebraic system of equations in Case I consists of four equations
only (equations derived basing on Formula (8) are equivalent to zero), while Case II
consists of five equations (equation derived basing on Formula (8) is equivalent to zero).

Figure 5. Visualisation of the assumed fluctuation shape functions: (a) \( \tilde{g}_1 \), (b) \( \tilde{h}_{11} \), (c) \( \tilde{h}_{12} \).

The tolerance model of vibrations of the three-layered sandwich plate, which takes
into considerations all of the above assumptions, is used to evaluate free vibrations of
36 different sandwich structures. Each of them is also investigated using an FEM model
created in Abaqus. Within this method the whole structure is modelled with the use of
eight-node brick elements with reduced integration (C3D8R) and proper boundary conditions.
The core of the structure is analysed using the sweep mesh, while the faces—the structured
mesh. For both parts, the approximated global size of elements is assumed to be 0.02 m, which
guarantees a good convergence of the results. In order to present the results in a concise form,
only the relative errors between tolerance models and FEM models are shown in Tables 1–4.
The relative error between the Tolerance Model in Case I and FEM model is denoted as
\( C_1 \), while \( C_2 \) stands for the relative error between the Tolerance Model in Case II and the FEM
model. Common dimensions and material properties of the structures are listed below:

\[
\begin{align*}
E_f &= 210 \text{ GPa}, \quad \nu_f = 0.3, \quad \rho_f = 7850 \text{ kg/m}^3, \\
E_c &= 5 \text{ GPa}, \quad \nu_c = 0.3, \quad \rho_c = 500 \text{ kg/m}^3, \\
h_f &= 0.0025 \text{ m}, \quad R = 0.05 \text{ m}, \quad Z = R - 2a, \\
l_1 &= \sqrt{3}R, \quad l_2 = 3R,
\end{align*}
\]
while the rest of the characteristic dimensions, such as the thickness of the core \( h_c \) and
thickness of the vertical wall of hex \( a \), are specified in Tables 1–4. Eventually, all calculations
are performed for three different dimensions of the structure, denoted as follows:

- Size I (S1)—\( L_1 = 10l_1, L_2 = 10l_2 \);
- Size II (S2)—\( L_1 = 20l_1, L_2 = 20l_2 \);
• Size III (S3)—$L_1 = 40l_1, L_2 = 20l_2$; and within several different modes, distinguished by wave numbers:
  • Mode I—$n = 1, m = 1$;
  • Mode II—$n = 1, m = 2$;
  • Mode III—$n = 1, m = 3$;
  • Mode IV—$n = 2, m = 1$;
  • Mode V—$n = 2, m = 2$;
  • Mode VI—$n = 3, m = 3$.

The results presented in Tables 1–4 should be properly interpreted, so several hints for modelling the vibrations of sandwich structures can be made. Let us formulate them in points.

• The relative errors between the results tend to decrease as the parameter $a$ (representing the thickness of the walls of honeycomb in the periodicity cell) raises. It should be noticed that the initially assumed in-plane displacement field, cf. (1), is dedicated to sandwich structures with cores filling the whole available space between faces. In the case of ‘thick’ honeycomb core, characterised by high values of parameter $a$, this assumption is still applicable, which results in generally satisfactory convergence of results. In the case of ‘thin’ honeycomb, this assumption is slowly corrupting. As a consequence, the relative errors between averaged solution and FEM can reach up to 25% (cf. $a = 0.005 \text{ m}, S_1$).

• There are significant differences in the results of the averaged models in Case I and Case II. The only difference between those cases is a set of fluctuation shape functions. It can be noticed that for structures with lower thickness of the core $h_c$, the assumption of negligibly small fluctuations of vertical displacements (Case II) is applicable. Hence, it produces results, which in general are convergent with the FEM analysis. Meanwhile, for higher values of the thickness $h_c$, it seems that the fluctuations of vertical displacements are more influential, hence they cannot be neglected (Case I).

• In order to obtain precise results within the averaged model, the considered structure should be made of a sufficiently large quantity of periodicity cells. It can be noticed that for relatively small periodic structures ($S_1$), the convergence of results in Case II is usually worse than in the case of larger structures ($S_2, S_3$). It can be caused by boundary conditions, which produce disturbances in displacement fields on a considerable span of the plate. A similar remark can be made for Case I, excluding structures with a low thickness of the core $h_c$, for which such a set of fluctuation shape functions is not applicable.

• Another reason for lower accuracy of results in the case of small periodic structures ($S_1$) can be the issue of slowly varying functions. Based on the definitions, a slowly varying function is a function, which is ‘almost’ constant on any periodicity cell, with respect to a certain tolerance parameter $\delta$. In the case of small periodic structures, this assumption can be satisfied only for higher values of parameter $\delta$, which results in lower accuracy of the proposed solution.

• It can be noticed that in several cases the discrepancies in the results between the averaged model and FEM analysis tend to raise higher modes of vibrations. The reason for this phenomenon can be also connected with difficulties in satisfying the condition of nearly constant values of slowly varying functions on a basic periodicity cell. In the case of higher modes of vibrations, this condition must yield higher values of tolerance parameter $\delta$ and, consequently, lower accuracy of the obtained results. Nevertheless, with a properly adjusted fluctuation shape functions, the averaged model can be used to estimate several basic free vibration frequencies of any of the analysed sandwich structures.
### Table 1. The relative errors between averaged models and FEM model for $a = 0.005$ m.

| $h_c$ [mm] | Mode | $S_1$ | $S_2$ | $S_3$ |
|------------|------|-------|-------|-------|

7. Final Remarks

In this article, the application of the tolerance averaging technique in the vibration analysis of a three-layered sandwich plate with a honeycomb core is presented. Despite the periodic microstructure of the core, the derived averaged model of the considered plate, based on the zig-zag hypothesis, is characterised by constant coefficients. Since the analytical solution to such a system of governing equations is relatively simple to obtain, this feature should be considered as the greatest finding of this work. Moreover, the proposed solution takes into consideration the microscale fluctuations of displacements. This feature is unreachable for other analytical methods, such as an asymptotic homogenisation method or other methods based on evaluation of effective properties of the heterogeneous layers.

In the calculation example, the free vibration analysis of the three-layered structure with basic honeycomb core is performed. Based on the results shown in Tables 1–4, one can conclude that the presented averaged solution is capable of providing reasonably precise results. However, their convergence with FEM analysis is highly dependent on several factors, such as the introduced fluctuation shape functions or the dimensions of the structure. As a consequence, the application of the averaged models in the analysis of such structures requires either ‘an engineering intuition’ or a previous experience in tolerance modelling, which stands for an unquestionable drawback of the presented solution.

On the other hand, one can notice that there is a significant difference in computing time of the proposed analytical solution and FEM models. In the case of the tolerance model, most time-consuming calculations are connected with the evaluation of coefficients of the governing Equations (8). Depending on the amount of the assumed fluctuation shape functions those calculations can require more or less computing power. However, it can be noticed that afterward the obtained coefficients can be used to analyse multiple structures with different characteristic dimensions, as long as the shape of the inhomogeneity remains constant. Those multiple investigations are usually instantly performed even by basic modern computers. Meanwhile, the creation of the geometry of the microperiodic FEM model is already a time-consuming process. Moreover, due to the assumed inhomogeneities, those models usually require a highly refined mesh, in order to provide reliable results. As a consequence, the computing resources required to perform the analysis of a single structure within FEM is incomparably higher, than in the case of the presented averaged model. Hence, it can be stated that the derived analytical solution to the issue of vibrations of the microheterogeneous sandwich plate is an efficient, time-saving option of the analysis, when compared to the FEM numerical calculations.

Moreover, one should notice that the analytical solution brings many opportunities, which are unreachable for numerical models. During the evaluation of coefficients of the governing equations, one can assume certain properties of the structure as parameters. As a consequence, it is possible to derive a calculation algorithm, which instantly produce relations between certain results and those parameters, in a large scope of calculation cases. Such relations are extremely useful during the optimisation process.

Moreover, let us emphasise that the presented solution is suitable for any kind of periodic microstructure of the core or faces. Hence, any type of periodic sandwich plate can be modelled with exactly the same calculation algorithm. In the case of the sandwich plates with honeycomb core, it is particularly important as honeycombs can differ from each other not only with dimensions $a$, $R$ and $Z$, but also with an angle $\phi$ (cf. Figure 4) or even they can have different thicknesses of vertical and skew walls. In the case of tolerance modelling, all those geometries require the proper adjustment of the periodicity cell’s definition and fluctuation shape functions only. Hence, the presented solution can be considered a convenient tool for the optimisation process. In very special cases, for example, auxetic honeycombs, some additional adjustments may be required, but such structures were not yet investigated.

Eventually, let us state that in order to validate the proposed averaged solution a comparison with experimental results should be made. Such work will be carried out in the nearest future.
