(Dated: June 14, 2021)

We compute spin-orbit torques (SOTs) in strained PtMnSb from first principles. We consider both tetragonal strain and shear strain. We find a strong linear dependence of the field-like SOTs on these strains, while the antidamping SOT is only moderately sensitive to shear strain and even insensitive to tetragonal strain. We also study the dependence of the SOT on the magnetization direction. In order to obtain analytical expressions suitable for fitting our numerical \textit{ab-initio} results we derive a general expansion of the SOT in terms of all response tensors that are allowed by crystal symmetry. Our expansion includes also higher-order terms beyond the usually considered lowest order. We find that the dependence on the strain is much smaller for the higher-order terms than for the lowest order terms. In order to judge the sensitivity of the SOT to the exchange correlation potential we compute the SOT in both GGA and LDA. We find that the higher-order terms depend significantly on the exchange-correlation potential, while the lowest order terms are insensitive to it. Since the higher-order terms are small in comparison to the lowest order terms the total SOT is insensitive to the exchange correlation potential in strained PtMnSb.

I. INTRODUCTION

The spin-orbit torque (SOT) allows us to switch the magnetization by electric current in noncentrosymmetric bulk crystals and in bilayers with structural inversion asymmetry \cite{1}. It therefore paves the way to novel spintronic memory devices. Among the noncentrosymmetric bulk crystals the half-metallic half-Heusler compounds are promising for spintronics applications \cite{2,3}. In particular, their high conduction-electron spin-polarization enhances for example the tunneling magnetoresistance and the giant magnetoresistance \cite{4,5}, and their half-metallicity suppresses the Gilbert damping \cite{10}.

The SOT in the half-Heusler NiMnSb depends strongly on the strain, which may be controlled by varying the substrate \cite{11,12}. Notably, NiMnSb thin films sputtered on GaAs substrates yield SOT effective fields per applied current that are similar in magnitude to those in Pt/Co/AlO\(_x\) magnetic bilayers \cite{13}. Tetragonal strain adds Dresselhaus spin-orbit interaction (SOI) to the microscopic half-Heusler Hamiltonian, while shear strain supplements it with both Rashba and Dresselhaus SOI.

The SOTs arising from Dresselhaus and Rashba SOI correspond to the lowest order in the expansion of the SOT with respect to the magnetization \cite{14}. In magnetic bilayers the higher-order terms in this expansion have been found to be sizeable in experiments \cite{12}, and several theoretical works have therefore considered the dependence of the SOT on the magnetization direction in detail in these bilayer systems \cite{15,16}. However, in the case of half-Heusler crystals the higher-order contributions in the expansion of the SOT in terms of the directional cosines of the magnetization have not yet been considered. Therefore, our symmetry analysis of the SOT in this paper includes also the first higher-order terms in the directional cosine expansion. Such angular expansions may be used to fit experimental SOT data \cite{15}. In the present paper we use the angular expansion in order to fit our \textit{ab-initio} data, which allows us to separate the SOT into the lowest-order Dresselhaus and Rashba SOI contributions and the remaining higher-order terms.

PtMnSb is a promising material for spintronics applications. Its half-metallicity has been established both experimentally and theoretically. It can be grown epitaxially on MgO(001) \cite{19} and on W(001)/MgO(001) \cite{20}. It exhibits a giant magneto-optical Kerr effect \cite{21,22}, which makes it attractive for magneto-optical recording. Furthermore, it exhibits a negative anisotropic magnetoresistance and it has been used for room-temperature giant magnetoresistance devices \cite{23,24}. In this paper we discuss the SOT in PtMnSb with tetragonal and shear strain obtained from first principles density-functional theory calculations.

This paper is structured as follows: In Sec. \textbf{II} we discuss the form of the SOT expected in half Heuslers based on the symmetry of the cubic, tetragonally strained, and shear-strained crystals. The tetragonally strained case is discussed in detail in Sec. \textbf{III} while the cubic and the shear-strained cases are discussed in detail in the Appendices \textbf{A} and \textbf{B}. In Sec. \textbf{III} we present our \textit{ab-initio} results on the SOTs in PtMnSb. In Sec. \textbf{III A} we describe the computational details. In Sec. \textbf{III B} we discuss the results on the odd torque and in Sec. \textbf{III C} we discuss the results on the even torque. This paper ends with a summary in Sec. \textbf{IV}.

II. SYMMETRY OF SOTS IN HALF-HEUSLER CRYSTALS

Similar to the conductivity tensor, which measures the response of the electric current to an applied electric field in linear response, we introduce the torque tensor to quantify the response of the torque to an applied electric field \[23\]. The torque \( T \) acting on the magnetization in one crystal unit cell is written as

\[
T = \sum_{ij} \hat{e}_i t_{ij} E_j ,
\]

where \( t_{ij} \) is the torque tensor, \( E_j \) is the \( j \)-th component of the applied electric field, and \( \hat{e}_i \) is a unit vector in the \( i \)-th Cartesian direction. In cubic and tetragonally strained PtMnSb the crystal lattice vectors \( a \), \( b \), and \( c \) used in the following sections are related to \( \hat{e}_i \) by \( a = a \hat{e}_1 \), \( b = b \hat{e}_2 \), and \( c = c \hat{e}_3 \), where \( a \), \( b \), and \( c \) are the lattice constants. In shear-strained PtMnSb we choose the \( a \) and \( b \) axes as follows:

\[
a = a \left( \cos \frac{\epsilon}{2}, \sin \frac{\epsilon}{2}, 0 \right)^T,
\]

\[
b = a \left( \sin \frac{\epsilon}{2}, \cos \frac{\epsilon}{2}, 0 \right)^T ,
\]

where we use \( \epsilon = 90^\circ - \gamma \) to quantify the shear strain, and \( \gamma \) is the angle between the \( a \) and \( b \) axes.

We separate the torque into even and odd parts with respect to inversion of the magnetization direction, i.e., \( t(\hat{M}) = t^{\text{even}}(\hat{M}) + t^{\text{odd}}(\hat{M}) \), where \( t^{\text{even}}(\hat{M}) = [\hat{t} \hat{M} + \hat{t}(-\hat{M})]/2 \) and \( t^{\text{odd}}(\hat{M}) = [\hat{t}(\hat{M}) - \hat{t}(-\hat{M})]/2 \). The corresponding even SOT is often referred to as the antidamping SOT, while the odd SOT is often referred to as the field-like SOT. \( t_{ij} \) is an axial tensor of rank 2. It is possible to use the symmetries of the half-Heusler crystal in order to determine the form of \( t_{ij} \). In practice only the torque perpendicular to the magnetization is of relevance and our \textit{ab-initio} approach described in Sec. IIIA computes only this perpendicular component by construction. However, in general, an axial tensor of rank 2 consistent with the crystal symmetry may predict also a component of the torque that is parallel to the magnetization. In order to avoid this irrelevant component we consider instead the symmetry of the effective magnetic field \( B \) that one would have to apply in order to generate a torque of the same size as the SOT. After determining the symmetry-allowed form of the response of \( B \) to an applied electric field we may subsequently obtain the torque from \( T = \mu \hat{M} \times B \). Here, \( \mu \) is the magnetic moment within one unit cell and \( \hat{M} \) is its direction. This approach guarantees that the torque \( T \) is perpendicular to the magnetization such that it is not necessary to remove irrelevant contributions obtained from symmetry analysis.

A. Odd torque

The effective field of the odd torque can be expressed in terms of the electric field \( E \) and the magnetization direction \( \hat{M} \) as follows:

\[
B^{\text{odd}}_i = \chi^{(a)}_{ij} E_j + \chi^{(a)}_{ijkl} \hat{M}_k \hat{M}_l + \ldots
\]

Here, \( \chi^{(a)}_{ij} \) is an axial tensor of second rank, \( \chi^{(a)}_{ijkl} \) is an axial tensor of fourth rank and summation over repeated indices is implied. Note that the effective field of the odd torque is even in the magnetization: \( B^{\text{odd}}(\hat{M}) = B^{\text{odd}}(-\hat{M}) \) because of \( T^{\text{odd}} = \mu \hat{M} \times B^{\text{odd}} \) (in our notation the torque \( T \) carries the superscript ‘odd’, when it is odd in the magnetization, i.e., \( T^{\text{odd}}(\hat{M}) = -T^{\text{odd}}(-\hat{M}) \), while the effective magnetic field \( B \) carries the superscript ‘odd’, when it is odd). In order to express the symmetry-allowed tensors \( \chi^{(a)}_{ij} \) and \( \chi^{(a)}_{ijkl} \) in terms of basis tensors we introduce the following notation to define these basis tensors:

\[
\delta^{(mn)}_{ij} = \delta_{im} \delta_{jn} \rightarrow \langle mn \rangle
\]

and

\[
\delta^{(mnpq)}_{ijkl} = \delta_{im} \delta_{jn} \delta_{ko} \delta_{lp} \rightarrow \langle mnop \rangle .
\]

The superscripts \( \langle mn \rangle \) and \( \langle mnpq \rangle \) serve to label the basis tensors. As a simple example to illustrate the use of these basis tensors consider the unit matrix. The unit matrix can be expressed as follows:

\[
\delta_{ij} = \delta^{(11)}_{ij} + \delta^{(22)}_{ij} + \delta^{(33)}_{ij} ,
\]

or simply \( \langle 11 \rangle + \langle 22 \rangle + \langle 33 \rangle \). Similarly, any given tensor may be expressed in terms of these basis tensors. The symmetry-allowed form of the torkance tensor depends on the crystallographic point group \[14,26\]. Cubic, tetragonally-strained, and shear-strained PtMnSb possess different crystallographic point groups. Therefore, we discuss the symmetry-allowed form of the torkance tensor separately for these three cases in the following. Note that in Eq. (3) we expand the effective field only in terms of the applied electric field and in terms of the magnetization but we do not expand it in terms of the strain. This is a major difference to the treatment of e.g. the piezomagnetic effects in Ref. [26], where the strain itself is considered as a perturbation. Instead, we assume here that the strain is constant and that it determines the symmetry-allowed form of the response tensor by affecting the crystallographic point group.
TABLE I. List of axial tensors of ranks 2 and 4 allowed by symmetry in tetragonally strained half Heuslers. The notation introduced in Eq. (5) is used. Arrows indicate tensors that may be replaced by others due to permutations of indices, while \( \chi \) denotes tensors that may be replaced by others due to Eq. (6).

| # | \( \chi^{(a\#)} \) | # | \( \chi^{(a\#)} \) | Remark |
|---|---|---|---|---|

| 5 | (3131) \( \rightarrow \) (3232) | 11 | (2222) \( \rightarrow \) (1111) | |

Tetragonal strain

First, we consider the case of tetragonal strain. The cases of shear strain and of cubic half Heuslers are discussed in Appendix A. For \( a = b \neq c \) and \( \alpha = \beta = \gamma = 90^\circ \) (point group 42m) we list the 11 axial tensors of rank 2 and 4 that are allowed by symmetry in Table I. In Eq. (6), the indices \( k \) and \( l \) of \( \chi_{ijkl}^{(a)} \) both couple to magnetization and are therefore interchangeable. Therefore, as indicated in Table I by arrows,

\[
\begin{align*}
\chi_{ijkl}^{(a10)} &= -\chi_{ijkl}^{(a2)} \\
\chi_{ijkl}^{(a7)} &= \chi_{ijkl}^{(a5)} \\
\chi_{ijkl}^{(a8)} &= \chi_{ijkl}^{(a6)} \\
\end{align*}
\]

Moreover, we find

\[
\chi_{ijkl}^{(a3)} - \chi_{ijkl}^{(a9)} - \chi_{ijkl}^{(a11)} \hat{M}_k \hat{M}_l = -\chi_{ij}^{(a1)}.
\]

Thus, we do not need to consider the tensors 10, 7, 8 and 11 when we express \( \chi_{ijkl}^{(a)} \) in terms of the tensors in Table I. Consequently, we can express the tensors in Eq. (8) as

\[
\begin{align*}
\chi_{ij}^{(a)} &= \alpha_1 \chi_{ij}^{(a1)} \\
\chi_{ijkl}^{(a)} &= \alpha_2 \chi_{ijkl}^{(a2)} + \alpha_3 \chi_{ijkl}^{(a3)} + \alpha_4 \chi_{ijkl}^{(a4)} + \\
&+ \alpha_5 \chi_{ijkl}^{(a5)} + \alpha_6 \chi_{ijkl}^{(a6)} + \alpha_7 \chi_{ijkl}^{(a7)} \\
\end{align*}
\]

in terms of 7 expansion coefficients \( \alpha_1, \ldots, \alpha_7 \). The tensor \( \chi_{ij}^{(a1)} = \delta_{ij}^{(22)} - \delta_{ij}^{(11)} \) describes the effective SOT field from Dresselhaus SOI. The tensors 2, 3, 4, 5, 6, and 9 describe higher-order contributions to the SOT, which have not yet been discussed in the literature.

The odd torque \( T^{\text{odd}} \) is related to its effective field by

\[
T_{ij}^{\text{odd}} = \Xi_{ij} B_{ij}^{\text{odd}},
\]

where

\[
\Xi = \mu \begin{pmatrix}
0 & -\hat{M}_3 & \hat{M}_2 \\
\hat{M}_3 & 0 & -\hat{M}_1 \\
-\hat{M}_2 & \hat{M}_1 & 0
\end{pmatrix}.
\]

Using Eq. (3), Eq. (2), and Eq. (10) we obtain

\[
T^{\text{odd}} = t^{\text{odd}} \hat{E},
\]

where

\[
t^{\text{odd}} = \mu \sum_{k=1}^{7} \alpha_k t_{ij}^{(oddk)}
\]

with

\[
g^{(odd1)} = \begin{pmatrix}
0 & -\hat{M}_3 & 0 \\
-\hat{M}_3 & 0 & 0 \\
\hat{M}_2 & \hat{M}_1 & \hat{M}_0
\end{pmatrix}
\]

\[
g^{(odd2)} = \begin{pmatrix}
-\hat{M}_1 \hat{M}_2 \hat{M}_3 & 0 & 0 \\
0 & -\hat{M}_1 \hat{M}_2 \hat{M}_3 & 0 \\
\hat{M}_2 \hat{M}_3 & \hat{M}_1 \hat{M}_2 & \hat{M}_0
\end{pmatrix}
\]

\[
g^{(odd3)} = \begin{pmatrix}
0 & \hat{M}_2 \hat{M}_3 & 0 \\
\hat{M}_2 \hat{M}_3 & 0 & 0 \\
-\hat{M}_2 \hat{M}_3 & \hat{M}_1 \hat{M}_2 & \hat{M}_0
\end{pmatrix}
\]

\[
g^{(odd4)} = \begin{pmatrix}
0 & 0 & \hat{M}_3 \hat{M}_2 \\
0 & 0 & \hat{M}_3 \hat{M}_2 \\
0 & \hat{M}_3 \hat{M}_2 & \hat{M}_1 \hat{M}_2
\end{pmatrix}
\]

\[
g^{(odd5)} = \begin{pmatrix}
\hat{M}_3 \hat{M}_2 \hat{M}_3 & -\hat{M}_2 \hat{M}_3 & 0 \\
-\hat{M}_2 \hat{M}_3 & \hat{M}_1 \hat{M}_2 \hat{M}_3 & 0 \\
0 & 0 & 0
\end{pmatrix}
\]

\[
g^{(odd6)} = \begin{pmatrix}
0 & 0 & \hat{M}_3 \hat{M}_2 \\
0 & 0 & \hat{M}_3 \hat{M}_2 \\
0 & \hat{M}_3 \hat{M}_2 & \hat{M}_1 \hat{M}_2
\end{pmatrix}
\]

\[
g^{(odd7)} = \begin{pmatrix}
0 & 0 & \hat{M}_3 \\
0 & 0 & \hat{M}_3 \\
0 & \hat{M}_3 & \hat{M}_1 \hat{M}_2
\end{pmatrix}
\]

Since

\[
g^{(odd2)} + g^{(odd5)} - g^{(odd3)} + g^{(odd7)} = g^{(odd1)}
\]

we can set \( \alpha_7 = 0 \) in Eq. (15). Thus, the odd torque tensor can be expressed in terms of 6 tensors \( g^{(odd1)}, \ldots, g^{(odd6)} \):

\[
t_{ij}^{\text{odd}} = \sum_{k=1}^{6} \beta_k g_{ij}^{(oddk)}
\]

with expansion coefficients \( \beta_1, \ldots, \beta_6 \). By fitting Eq. (16) to the odd torque given for a set of magnetization directions, one may determine the coefficients \( \beta_i \) and subsequently use Eq. (16) to predict the odd torque for any magnetization direction.

B. Even torque

The effective field of the even torque can be expressed in terms of the electric field \( \hat{E} \) and the magnetization direction \( \hat{M} \) as follows:

\[
B_{ij}^{\text{even}} = \chi_{ijkl}^{(p)} \hat{E}_k \hat{M}_l + \chi_{ijklmn}^{(p)} \
\]

\[
\hat{E}_k \hat{M}_l \hat{M}_m + \ldots
\]
Here, $\chi_{iklm}^{(p)}$ is a polar tensor of third rank, $\chi_{ijklm}^{(p)}$ is a polar tensor of fifth rank and summation over repeated indices is implied. Note that the effective field of the even torque is odd in the magnetization.

**Tetragonal strain**

**TABLE II.** List of polar tensors of rank 3 and 5 allowed by symmetry in tetragonally strained half Heuslers. The notation introduced in Eq. (18) is used. Arrows indicate tensors that may be replaced by others due to permutation of indices, while $\longleftrightarrow$ denotes tensors that may be replaced by others due to Eq. (18).

| # | $\chi^{(p\#)}$ | Note | # | $\chi^{(p\#)}$ | Note |

| 1 | $321 + 312$ | $18(13121) + (23122)$ | $→$ 17 | | |
| 2 | $231 + 132$ | $19(22321) + (11312)$ | $→$ 6 | | |
| 3 | $213 + 123$ | $20(11321) + (22312)$ | $→$ 6 | | |
| 4 | $33231 + 33132$ | $21(31211) + (32122)$ | $→$ 15 | | |
| 5 | $33321 + 33312$ | $→$ 4 | $22(13211) + (23122)$ | $→$ 17 | | |
| 6 | $22231 + 11312$ | $23(32111) + (31222)$ | $→$ 18 | | |
| 7 | $32331 + 31332$ | $24(31211) + (13222)$ | $→$ 18 | | |
| 8 | $32331 + 13332$ | $25(12311) + (21322)$ | $→$ 18 | | |
| 9 | $33231 + 33132$ | $→$ 4 | $26(21311) + (12322)$ | $→$ 18 | | |
| 10 | $32313 + 31323$ | $→$ 7 | $27(11231) + (22132)$ | $→$ 6 | | |
| 11 | $23313 + 13323$ | $→$ 8 | $28(12311) + (21322)$ | $→$ 25 | | |
| 12 | $32133 + 31233$ | $→$ 9 | $29(21311) + (12322)$ | $→$ 26 | | |
| 13 | $23133 + 13233$ | $→$ 9 | $30(22311) + (11322)$ | $→$ 6 | | |
| 14 | $23133 + 13233$ | $→$ 9 | $31(11231) + (22132)$ | $→$ 6 | | |
| 15 | $31212 + (32122)$ | $32(12111) + (21322)$ | $→$ 25 | | |
| 16 | $32212 + (31122)$ | $→$ 15 | $33(21111) + (12322)$ | $→$ 26 | | |
| 17 | $23221 + (13121)$ | $→$ 18 | | | |

Here, we discuss the case of tetragonal strain. The cases of shear strain and of cubic half Heuslers are discussed in Appendix [I]. For $a = b ≠ c$ and $α = β = γ = 90°$ we list the polar tensors that are allowed by symmetry in Table [II]. In Eq. (17), the indices $k, l$ and $m$ of $\chi_{ijkm}^{(p)}$ are contracted with the magnetization direction and are therefore interchangeable. Tensors that are related to other tensors by interchange of the indices $k, l$ and $m$ are specified in Table [II] by arrows. These tensors do not need to be considered when we expand $\chi_{ijklm}^{(p)}$. When considering the permutations of the indices $k, l$ and $m$ the list of independent tensors that are needed in the expansion of $\chi_{ijklm}^{(p)}$ is therefore reduced to the following ones: 1, 2, 3, 4, 6, 7, 8, 14, 15, 17, 23, 24, 25, 26.

Due to the relations

$$\Xi_n[\chi_{ijklm}^{(p4)} + 2\chi_{ijklm}^{(p17)}] M_k M_l M_m = 0$$

$$\Xi_n[\chi_{ijklm}^{(p6)} + \chi_{ijklm}^{(p7)} + \chi_{ijklm}^{(p25)}] M_k M_l M_m = 0$$

$$\chi_{ijklm}^{(p7)} + \chi_{ijklm}^{(p15)} + \chi_{ijklm}^{(p23)} M_k M_l M_m = \chi_{ijkl} M_k$$

$$\chi_{ijklm}^{(p8)} + \chi_{ijklm}^{(p17)} + \chi_{ijklm}^{(p24)} M_k M_l M_m = \chi_{ijkl} M_k$$

$$\chi_{ijklm}^{(p14)} + \chi_{ijklm}^{(p14)} + \chi_{ijklm}^{(p26)} M_k M_l M_m = \chi_{ijkl} M_k$$

we do not need to consider the tensors 17, 23, 24, 25, and 26. This leaves us with 3 polar tensors of rank 3 and 6 polar tensors of rank 5 to describe the SOT effective magnetic field in the tetragonal case, i.e., 9 tensors in total.

Using $T^{even} = \mu \tilde{M} \times B^{even}$ and $T^{even} = \ell^{even} E$, we arrive at

$$t_{ijkl}^{even} = \mu \sum_{k=1}^{9} \gamma_k \ell_{ijkl}^{(even)}$$  \hspace{1cm} (19)

with

$$\ell^{(even1)} = \begin{pmatrix} \hat{M}_2 M_1 M_3 & 0 & 0 \\ -\hat{M}_2 M_1 & \hat{M}_2 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

$$\ell^{(even2)} = \begin{pmatrix} 0 & 0 & -\hat{M}_1 M_3 \\ 0 & \hat{M}_2 M_3 & 0 \\ 0 & 0 & \hat{M}_2 + M_1^2 \end{pmatrix}$$

$$\ell^{(even3)} = \begin{pmatrix} -\hat{M}_3^2 & 0 & 0 \\ 0 & \hat{M}_3 & 0 \\ \hat{M}_3 M_1 - \hat{M}_2 M_3 & 0 \end{pmatrix}$$

$$\ell^{(even4)} = \begin{pmatrix} 0 & 2\hat{M}_1 M_3 M_2 & \hat{M}_3 \\ 0 & 0 & 0 \\ 0 & 0 & M_2 + M_3 \end{pmatrix}$$

$$\ell^{(even5)} = \begin{pmatrix} 0 & -\hat{M}_1 M_3 M_2 & \hat{M}_3 \\ -\hat{M}_1 M_2 M_3 & 0 & 0 \\ \hat{M}_2 M_3 M_1 & 0 & 0 \end{pmatrix}$$

$$\ell^{(even6)} = \begin{pmatrix} \hat{M}_3 M_1 M_2 & 0 & 0 \\ -\hat{M}_1 M_2 M_3 & \hat{M}_2 M_1 M_3 & 0 \\ 0 & 0 & \hat{M}_2 M_3 M_1 - \hat{M}_1 M_2 M_3 \end{pmatrix}$$

$$\ell^{(even7)} = \begin{pmatrix} 0 & 0 & -\hat{M}_3 M_1 M_2 \\ 0 & \hat{M}_3 M_1 M_2 & 0 \\ 0 & 0 & \hat{M}_3 M_1 M_2 \end{pmatrix}$$

$$\ell^{(even8)} = \begin{pmatrix} 0 & 0 & 0 \\ \hat{M}_4 M_3 & 0 & 0 \\ 0 & \hat{M}_3 M_1 M_2 & 0 \end{pmatrix}$$

$$\ell^{(even9)} = \begin{pmatrix} \hat{M}_2 M_3 M_1 & 0 & 0 \\ -\hat{M}_1 M_2 M_3 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

We performed electronic structure calculations of PtMnSb based on the generalized gradient approximation (GGA) as implemented in the FLEUR program. The unit cell is shown in Fig. 1. In order to calculate how sensitive the SOT is to the exchange correlation functional, we performed additional calculations within the local density approximation (LDA) as described in Ref. [25] with the help of Wannier90 code in order to sample the Brillouin zone, where \( \psi_{kn} \) and \( \tilde{T}_i \) denote the Bloch function for band \( n \) at \( k \)-point \( k \) and the corresponding band energy, respectively. A constant magnetic moment slightly deviates from the integer value \( \mu_B \). This deviation depends on the strain and on the magnetization direction, but it is at most 1% for the even torkance of one unit cell.

The even torkance is given by

\[
\tau_{ij}^{\text{even}} = \frac{e\hbar}{2\pi N} \sum_{knm} \text{Im} \left\{ \frac{\Gamma(\epsilon_{kn} - \epsilon_{km})}{[(\epsilon_F - \epsilon_{kn})^2 + \Gamma^2] [(\epsilon_F - \epsilon_{km})^2 + \Gamma^2]} + \frac{2\Gamma}{[\epsilon_{kn} - \epsilon_{km}] [(\epsilon_F - \epsilon_{km})^2 + \Gamma^2]} + \frac{2}{\epsilon_{kn} - \epsilon_{km}} \text{Im} \log \frac{\epsilon_{kn} - \epsilon_F - i\Gamma}{\epsilon_{km} - \epsilon_F - i\Gamma} \right\}
\]

and the odd torkance is given by

\[
\mu_{ij}^{\text{odd}} = \frac{e\hbar}{\pi N} \sum_{knm} \frac{\Gamma^2 \text{Re} \left\{ \frac{\langle \psi_{kn} | \tilde{T}_i | \psi_{km} \rangle \langle \psi_{kn} | \psi_{km} \rangle \langle \psi_{kn} | v_j | \psi_{kn} \rangle \rangle}{[(\epsilon_F - \epsilon_{kn})^2 + \Gamma^2] [(\epsilon_F - \epsilon_{km})^2 + \Gamma^2]}},
\]

where \( N \) is the number of \( k \)-points used to sample the Brillouin zone, \( e \) is the elementary positive charge, \( \tilde{T}_i \) is the \( i \)-th Cartesian component of the torque operator, \( \Gamma \) is the quasiparticle broadening, and \( \psi_{kn} \) and \( \epsilon_{kn} \) denote the Bloch function for band \( n \) at \( k \)-point \( k \) and the corresponding band energy, respectively. A constant broadening of \( \Gamma = 25 \text{ meV} \) was used in the calculations unless noted otherwise.

Due to the half-metallicity the spin magnetic moment per unit cell takes the integer value \( \mu = 4\mu_B \) when SOI is not included in the calculations, where \( \mu_B \) is Bohr’s magneton. When we compute the magnetic moments contained in muffin-tin spheres around the atoms, we find that Mn contributes most to the total magnetic moment. In detail the atomic magnetic moments (in units of \( \mu_B \)) obtained in GGA (LDA) are as follows: 3.91 (3.8) on Mn, 0.11 (0.14) on Pt, and -0.072 (-0.047) on Sb.

In our calculations of SOT we include SOI and therefore the magnetic moment slightly deviates from the integer value \( \mu = 4\mu_B \). This deviation depends on the strain and on the magnetization direction, but it is at most 1% for the strains that we consider. Therefore, \( \mu \approx 4\mu_B \) is very well satisfied in all our calculations. When we present our \textit{ab initio} results we use \( e\alpha_0 \approx 8.478 \times 10^{-30} \text{Cm} \) as the unit of torkance. A torkance of one \( e\alpha_0 \) corresponds therefore to an effective magnetic field of \( B = e\alpha_0 E/\mu \approx 0.229 \mu_T \) when the applied electric field is \( E = 1 \text{ V/m} \).

In Ref. [25] we have shown that the odd SOT is proportional to \( 1/\Gamma \) in the limit \( \Gamma \to 0 \), while the even SOT is independent of \( \Gamma \) in this limit. Therefore, it may be convenient to discuss the odd SOT per applied electric current, because this ratio is independent of \( \Gamma \) in the limit of \( \Gamma \to 0 \). The resistivity of cubic PtMnSb at \( \Gamma = 25 \text{ meV} \) is given by \( \rho_{xx} = 17\mu\Omega \text{cm} \), which we computed using the equations given in Ref. [25]. Consequently, an odd torkance of one \( e\alpha_0 \) at \( \Gamma = 25 \text{ meV} \) corresponds to an effective magnetic field per electric current-density ratio of \( B/j = e\alpha_0 E/(\mu j) = e\alpha_0 \rho_{xx}/\mu \approx 3.89 \times 10^{-14} \text{ Tm}^2/\text{A}. \)
B. Odd torque

In Fig. 2 we show the odd torque as a function of the azimuthal angle of the magnetization for different tetragonal strains. Strain increases the odd torque significantly. At large strain the odd SOT is of the same order of magnitude as in experiments on NiMnSb [13]. A suitable substrate on which PtMnSb[100] grows under tetragonal strain is W[100]. For W the theoretically estimated misfit strain is 2.1%, while the evaluation of diffraction data yields an estimated in-plane tensile strain of 0.31%-0.52% [20].

In the tetragonal systems the differences between the torques computed with GGA (filled circles) and LDA (filled triangles) are very small. However, in the cubic system GGA and LDA differ even qualitatively: Here, the torque has maxima close to 120° and close to 240° when GGA is used. However, when LDA is used it has a maximum at 0° instead. When we use Eq. [16] to fit the ab-initio results we obtain very good agreement between the fit and the data, as shown in the figure.

In Fig. 3 we show the odd torque as a function of the polar angle θ. It varies only moderately with the angle θ, in contrast to the strong variation with the angle φ shown in Fig. 2. When the tetragonal strain is η = 1.45% the odd torque is of the same order of magnitude as the even and odd torques in magnetic bilayers such as Co/Pt and Mn/W [23].

In Fig. 4 we show the strain-dependence of the parameters βk in Eq. [16] for several strains η = (c - c_{cub})/c_{cub} when the odd torque is obtained from GGA.

In Fig. 4 we show the strain-dependence of the parameters β_k in Eq. [16], which we use to fit the ab-initio results. In cubic PtMnSb we find that the relations...
Eq. (A8) are satisfied well. The coefficient $\beta_1$ varies linearly with strain and depends strongly on it, while the coefficients $\beta_2$ through $\beta_6$ are less sensitive to strain than $\beta_1$. In Eq. (16) $\beta_1$ is the coefficient of $\vartheta_{ij}^{(oddd)}$, which describes the SOT from Dresselhaus-type SOI. However, $\beta_1$ does not vanish for zero strain. Of course, this does not imply that there is a Dresselhaus field at $\eta = 0$. Instead, it is simply a manifestation of Eq. (15), which shows that $\vartheta_{ij}^{(oddd)}$ is not linearly independent from the higher order contributions described by the tensors 2, 3, 5, and 7.

In Eq. (16) we made the choice $\alpha_7 = 0$ in order to get an unambiguous representation of the torque in terms of a set of fitting parameters, which is only possible when we expand the torque in terms of linearly independent tensors. However, it is possible to choose a different combination of tensors such that the coefficient of $\vartheta_{ij}^{(oddd)}$ is zero at $\eta = 0$. Such a combination has the advantage that one may claim that the coefficient of $\vartheta_{ij}^{(oddd)}$ corresponds to the Dresselhaus SOI. For this purpose we perform a second fitting run after determining the parameters $\beta_1, ..., \beta_6$ in Eq. (16) in the first fitting run. The second fitting run is based on

$$\vartheta_{ij}^{(odd)} = \sum_{k=1}^{7} \beta_k' \vartheta_{ij}^{(oddk)}, \quad (23)$$

where we fix $\beta_7 = \beta_1(\eta = 0)$, while $\beta_1', ..., \beta_6'$ are free fitting parameters. As shown in Fig. 5 this two-step fitting procedure leads to $\beta_1'(\eta = 0) = 0$, which can be understood easily from Eq. (16). We can thus claim that $\beta_1'$ describes the SOT from the Dresselhaus field.

In Fig. 6 we show the expansion coefficients for the SOT obtained from LDA. Interestingly, the $\beta_1'$ in Fig. 5 and Fig. 6 differ by less than 1%. Thus, the differences between LDA and GGA, which are illustrated in Fig. 2, are reflected mostly by the differences in the higher-order coefficients $\beta_2', ..., \beta_7'$. These higher-order coefficients differ significantly between GGA and LDA. However, for sufficiently large strain the contribution of the higher-order terms is relatively small compared with the Dresselhaus SOT described by $\beta_1'$. Therefore, the odd SOT is insensitive to the choice of the exchange correlation potential in strained PtMnSb, as discussed already in Fig. 2.

Next, we discuss the effect of shear strain $\epsilon$ on the odd torque. In Fig. 7 we show the odd torque as a function of the azimuthal angle $\phi$ in the shear strained crystal. The enhancement of the odd SOT with shear strain is similarly strong as the enhancement with tetragonal strain. When the shear strain is $\epsilon = 2°$ the odd torque is of the same order of magnitude as the even and odd torques in magnetic bilayers such as Co/Pt and Mn/W [25].

FIG. 5. PtMnSb: Expansion coefficients $\beta_i'$ in Eq. (23) for several strains $\eta = (c - c_{cub})/c_{cub}$ when the odd torque is obtained from GGA.

FIG. 6. PtMnSb: Expansion coefficients $\beta_i'$ in Eq. (23) for several strains $\eta = (c - c_{cub})/c_{cub}$ when the odd torque is obtained from LDA.
At $\varepsilon = 2^\circ$ the odd torkance exhibits a maximum at $\phi = 0^\circ$. In order to investigate the dependence of this maximum on $\varepsilon$ we show in Fig. 8 the odd torkance at $\phi = 0^\circ$ as a function of $\varepsilon$. In the considered range the dependence on $\varepsilon$ is approximately linear.

In Fig. 9 we show the expansion coefficients $\beta_i$ in Eq. (A9) of the odd torkance in shear-strained PtMnSb obtained in GGA. At large shear strain $\beta_1$ dominates clearly over the other contributions, i.e., the SOT from Rashba SOI is dominant. Since shear strain automatically implies tetragonal strain, a SOT from Dresselhaus SOI—described by $\beta_2$—is present as well, but it is small compared to the SOT from Rashba SOI.

In Fig. 10 we show the even torque as a function of the azimuthal angle $\phi$ for several tetragonal strains $\eta = (c - c_{\text{cub}})/c_{\text{cub}}$ when the electric current is applied along [110] direction and when the magnetization is in-plane. $\phi$ is the angle between magnetization and the [110] direction. We show the component of the even torque that is parallel to the unit vector $e_\phi$ of the spherical coordinate system. Ab-initio data are shown by filled circles, while solid lines are fits according to Eq. (19).

In Fig. 9 we show the even torkance as a function of shear-strain $\varepsilon$ [°] in PtMnSb when the polar and azimuthal angles of magnetization are $\theta = 90^\circ$ and $\phi = 0^\circ$, respectively.

C. Even Torque
maximum even torkance is smaller than the maximum odd torkance by a factor of 12.5. In contrast to magnetic bilayer systems such as Co/Pt [13], where the even SOT is typically more important than the odd SOT, in PtMnSb the odd SOT dominates.

In contrast to magnetic bilayer systems such as Co/Pt [15], where the even torque is parallel to the unit vector \( e_\phi \) of the spherical coordinate system. Ab-initio data are shown by filled circles, while solid lines are fits according to Eq. [152].

In Fig. 11 we show the even torkance in shear-strained PtMnSb at \( \Gamma = 100 \) meV. While the even torkance is more sensitive to shear strain than to tetragonal strain, it is less sensitive to shear strain than the odd torkance.

IV. SUMMARY

We discuss the constraints that crystal symmetry imposes on the form of the SOT torkance tensor in half Heuslers with tetragonal or shear strain. We discuss the lowest order tensors, which correspond to Rashba and Dresselhaus SOI, but also higher order tensors. We perform first principles DFT calculations of the SOT in half-Heusler PtMnSb as a function of tetragonal and shear strain. The odd torkance in PtMnSb depends strongly on tetragonal strain, which we attribute to the Dresselhaus SOI. We find the SOT from Dresselhaus SOI to be insensitive to the exchange-correlation functional, i.e., the differences between GGA and LDA are negligible. In contrast, the higher-order tensors differ substantially between GGA and LDA. However, these higher-order contributions are small in PtMnSb with tetragonal strain, such that the total odd torkance in PtMnSb is insensitive to the exchange-correlation functional. The even torkance depends only weakly on tetragonal strain, but it depends moderately strong on shear strain. The dependence of the odd SOT on shear strain is similarly strong as its dependence on tetragonal strain and it arises mostly from Rashba SOI. In SOT-applications PtMnSb should be grown on suitable substrates that maximize strain in order to obtain large torkances. Our results show that in strained PtMnSb torkances of the same order of magnitude as in NiMnSb experiments may be achieved.

Appendix A: Symmetry analysis for the odd torque in cubic half Heuslers and in half Heuslers under shear strain

Cubic PtMnSb

In the following we discuss the odd torque for the case of cubic half Heuslers, i.e., \( a = b = c \) and \( \alpha = \beta = \gamma = 90^\circ \) (point group \( 43m \)). In contrast to the case with tetragonal strain, symmetry does not allow axial tensors of rank 2 in cubic PtMnSb [14]. The following axial tensors of rank 4 are allowed by symmetry:

\[
\chi^{(a12)}_{ijkl} = \delta^{(1212)}_{ijkl} - \delta^{(1212)}_{ijkl} - \delta^{(3131)}_{ijkl} + \delta^{(3232)}_{ijkl} + \delta^{(1313)}_{ijkl} - \delta^{(2323)}_{ijkl},
\]

\[
\chi^{(a13)}_{ijkl} = -\delta^{(2211)}_{ijkl} + \delta^{(1122)}_{ijkl} + \delta^{(3311)}_{ijkl} - \delta^{(3232)}_{ijkl} - \delta^{(1133)}_{ijkl} + \delta^{(2233)}_{ijkl},
\]

\[
\chi^{(a14)}_{ijkl} = -\delta^{(1221)}_{ijkl} + \delta^{(1212)}_{ijkl} + \delta^{(1331)}_{ijkl} - \delta^{(2332)}_{ijkl} - \delta^{(1133)}_{ijkl} + \delta^{(3223)}_{ijkl}.
\]

Since the indices \( k \) and \( l \) of \( \chi_{ijkl} \) both couple to magnetization in Eq. (3) and since

\[
\chi^{(a12)}_{ijkl} \hat{M}_k \hat{M}_l = \chi^{(a14)}_{ijkl} \hat{M}_k \hat{M}_l
\]

we do not need to consider \( \chi^{(a14)} \) when we expand \( \chi^{(a)}_{ijkl} \) in terms of the tensors in Eq. (A1). Comparison of these
tensors to Table II yields

\begin{align}
\chi_{ijkl}^{(a12)} &= \chi_{ijik}^{(a2)} - \chi_{i jkl}^{(a3)} - \chi_{ijkl}^{(a6)}, \\
\chi_{ijkl}^{(a13)} &= \chi_{ijkl}^{(a3)} - \chi_{ijkl}^{(a4)} - \chi_{ijkl}^{(a9)},
\end{align}

(A3)

Thus, for the cubic half Heuslers, we can express the tensors in Eq. (3) as follows:

\begin{align}
\chi_{ij}^{(a)} &= 0 \\
\chi_{ijkl}^{(a)} &= \alpha_{12} \chi_{ijkl}^{(a12)} + \alpha_{13} \chi_{ijkl}^{(a13)},
\end{align}

(A4)

with two coefficients \( \alpha_{12} \) and \( \alpha_{13} \) \[14\].

The corresponding torque is given by

\[ t_{ij}^{\text{odd}} = \mu \sum_{k=12}^{13} \alpha_k \hat{t}_{ij}^{(\text{odd}k)} = \sum_{k=12}^{13} \beta_k \hat{t}_{ij}^{(\text{odd}k)}, \]

(A5)

with

\[ g^{(\text{odd12})} = g^{(\text{odd2})} - g^{(\text{odd5})} - g^{(\text{odd6})} = \\
\begin{pmatrix}
-2 \hat{M}_1 \hat{M}_2 \hat{M}_3 & \hat{M}_2 \hat{M}_3 & \hat{M}_2 \hat{M}_3 \\
\hat{M}_2 \hat{M}_3 & -2 \hat{M}_1 \hat{M}_2 \hat{M}_3 & \hat{M}_1 \hat{M}_2 \hat{M}_3 \\
\hat{M}_2 \hat{M}_3 & \hat{M}_1 \hat{M}_2 \hat{M}_3 & -2 \hat{M}_1 \hat{M}_2 \hat{M}_3
\end{pmatrix}, \]

(A6)

and

\[ g^{(\text{odd13})} = g^{(\text{odd3})} - g^{(\text{odd4})} + g^{(\text{odd7})} = \\
\begin{pmatrix}
0 & \hat{M}_1^2 \hat{M}_3 - \hat{M}_3^3 - \hat{M}_2^3 + \hat{M}_2^2 \hat{M}_2 & \hat{M}_2 \hat{M}_3 - \hat{M}_3 \hat{M}_2 \\
\hat{M}_2 \hat{M}_3 - \hat{M}_3 \hat{M}_2 & 0 & -\hat{M}_3^3 + \hat{M}_1 \hat{M}_2 \hat{M}_2 \\
-\hat{M}_2 \hat{M}_3 - \hat{M}_3 \hat{M}_2 & -\hat{M}_3 \hat{M}_2 + \hat{M}_1 \hat{M}_2 \hat{M}_3 & 0
\end{pmatrix}. \]

(A7)

Instead of using Eq. (A5) to fit the odd torque in cubic PtMnSb one can of course also use Eq. (A10). By equating Eq. (A6) and Eq. (A10) we find that in cubic PtMnSb the following relations should be satisfied:

\[ \beta_1 = -\beta_4, \]

\[ 2\beta_1 = \beta_3, \]

\[ 2\beta_1 = -\beta_2 - \beta_5, \]

\[ \beta_6 = \beta_1 + \beta_5. \]

(A8)

The corresponding torque may be written as

\[ t_{ij}^{\text{odd}} = \sum_{\#=1}^{2} \beta_{\#} \Xi_{im} \chi_{mj}^{(a\#)} + \sum_{\#=3}^{22} \beta_{\#} \Xi_{im} \chi_{mjkl}^{(a\#)} \hat{M}_k \hat{M}_l, \]

(A9)

where the matrix \( \Xi \) is defined in Eq. (11). As discussed above, one may set \( \beta_{\#} = 0 \) for all tensors \( \# \) indicated by an arrow or by \( \emptyset \) in Table III i.e., \( \beta_0 = 0, \beta_7 = 0, \beta_8 = 0, \ldots \)].

\begin{table}[h]
\centering
\caption{List of axial tensors of rank 2 and 4 allowed by symmetry in shear-strained half Heuslers. The notation introduced in Eq. (A5) is used. Arrows indicate tensors that may be replaced by others due to permutation of indices, while \( \chi^{(a9)} \) denotes tensors that may be replaced by others due to Eq. (A10).}
\begin{tabular}{|c|c|c|}

\hline
\end{tabular}
\end{table}

Finally, we discuss the odd torque in the presence of shear strain.

We present the axial tensors of rank 2 and rank 4 that are allowed by symmetry in shear-strained half-Heuslers in Table III. As indicated by arrows in the Table, tensors \( 6, 7, 15, 16, 17, \) and \( 18 \) do not need to be considered because both indices \( k \) and \( l \) of \( \chi_{ijkl}^{(a)} \) couple to magnetization in Eq. (3) and these tensors may therefore be replaced by others. Additionally, tensor 8 does not need to be considered, because it evaluates to zero when both indices \( k \) and \( l \) of \( \chi_{ijkl}^{(a)} \) are contracted with the magnetization. Tensor 1 describes the SOT effective field from Rashba SOI, tensor 2 describes the SOT effective field from Dresselhaus SOI \[14\], and the remaining tensors describe higher-order contributions that have not yet been discussed in the literature. Tensor 2 appears also in the case of tetragonal strain, see the first tensor in Table III. This is expected, because shear strain is automatically accompanied by tetragonal strain.
0, \beta_{15} = 0, \ldots. However, due to the relations

\begin{align*}
\Xi_{im}(^{(1)}\chi_{m}) = \Xi_{im}(^{(4)}\chi_{ijkl}) \hat{M}_k \hat{M}_l &+ \Xi_{im}(^{(a12)}\chi_{ijkl}) \hat{M}_k \hat{M}_l \\
&+ \Xi_{im}(^{(a19)}\chi_{ijkl}) \hat{M}_k \hat{M}_l + \Xi_{im}(^{(a21)}\chi_{ijkl}) \hat{M}_k \hat{M}_l,
\Xi_{im}(^{(2)}\chi_{m}) = \Xi_{im}(^{(10)}\chi_{ijkl}) \hat{M}_k \hat{M}_l &+ \Xi_{im}(^{(a20)}\chi_{ijkl}) \hat{M}_k \hat{M}_l \\
&+ \Xi_{im}(^{(a22)}\chi_{ijkl}) \hat{M}_k \hat{M}_l,
\Xi_{im}(^{(3)}\chi_{m}) = \Xi_{im}(^{(10)}\chi_{ijkl}) \hat{M}_k \hat{M}_l &+ \Xi_{im}(^{(a13)}\chi_{ijkl}) \hat{M}_k \hat{M}_l,
\Xi_{im}(^{(4)}\chi_{ijk}) = \Xi_{im}(^{(a14)}\chi_{ijkl}) - \Xi_{im}(^{(a9)}\chi_{ijkl}) - \Xi_{im}(^{(a12)}\chi_{ijkl}) \hat{M}_k \hat{M}_l = 0
\end{align*}

(A10)

the remaining tensors in Eq. (A9) are not linearly independent. Therefore, we may additionally choose \beta_{21} = 0, \beta_{22} = 0, \beta_{13} = 0, and \beta_{12} = 0. Thus, only 11 independent tensors need to be considered in Eq. (A9) with 11 corresponding fitting parameters \beta_{\#}.

Appendix B: Symmetry analysis for the even torque in cubic half Heuslers and in half Heuslers under shear strain

Cubic PtMnSb

When \(a = b = c\) and \(\alpha = \beta = \gamma = 90^\circ\), symmetry allows 11 polar tensors of rank 3 and rank 5, which we list in Table IV.

| #  | \(\chi^{(p\#)}\)                          | Note                   |
|----|------------------------------------------|------------------------|
| 1  | (321) + (231) + (312) + (132) + (213) + (123) |                        |
| 2  | (1321) - (1231) - (2312) - (2132) - (3213) - (3123) |                        |
| 3  | (3221) + (2331) + (3112) + (1332) + (2113) + (1223) |                        |
| 4  | (3121) + (2131) + (3212) + (1232) + (2313) + (3233) | + \(\chi^{(p2)}\)     |
| 5  | (3211) + (2311) + (3122) + (2122) + (3222) + (3133) | + \(\chi^{(p3)}\)     |
| 6  | (1321) + (1231) + (2312) + (2132) + (3213) + (3123) | + \(\chi^{(p4)}\)     |
| 7  | (2321) + (3231) + (1312) + (1332) + (1213) + (2123) | + \(\chi^{(p5)}\)     |
| 8  | (1321) + (1231) + (2312) + (2132) + (3213) + (3123) | + \(\chi^{(p6)}\)     |
| 9  | (3321) - (2231) - (3312) - (1132) - (2213) - (1123) | + \(\chi^{(p7)}\)     |
| 10 | (3121) - (1321) - (3212) - (1232) - (2313) - (3233) | + \(\chi^{(p8)}\)     |
| 11 | (2321) - (3321) - (1312) - (3312) - (1132) - (2213) | + \(\chi^{(p9)}\)     |

In Eq. (17) the last three indices are contracted with the magnetization. Therefore, for the purpose of application in Eq. (17), \(\chi^{(p6)}_{ijklm}\) is equivalent with \(\chi^{(p2)}_{ijklm}\), \(\chi^{(p4)}_{ijklm}\) is equivalent with \(\chi^{(p3)}_{ijklm}\), and \(\chi^{(p9)}_{ijklm}\) is equivalent with \(\chi^{(p8)}_{ijklm}\), as indicated in the Table. Consequently, we do not need to consider \(\chi^{(p6)}_{ijklm}\), \(\chi^{(p4)}_{ijklm}\), and \(\chi^{(p9)}_{ijklm}\). Thus, the contribution to the effective field of the even SOT which is third order in \(\hat{M}\) can be expressed in terms of the tensor

\begin{align*}
\chi^{(p)}_{ijklm} = \alpha_2 \chi^{(p2)}_{ijklm} + \alpha_3 \chi^{(p3)}_{ijklm} + \alpha_5 \chi^{(p5)}_{ijklm} + \alpha_7 \chi^{(p7)}_{ijklm} \\
+ \alpha_8 \chi^{(p8)}_{ijklm} + \alpha_{10} \chi^{(p10)}_{ijklm} + \alpha_{11} \chi^{(p11)}_{ijklm}.
\end{align*}

(B1)

Finally, we consider the case of shear strain. In Table V we present the polar tensors of rank 3 and 5 allowed by symmetry in shear-strained half Heuslers. As indicated in the Table by arrows, several tensors may be replaced by others, because in Eq. (17) the indices \(k, l\) and \(m\) of \(\chi^{(p)}_{ijklm}\) are interchangeable.
TABLE V. List of polar tensors of rank 3 and 5 allowed by symmetry in shear-strained half Heuslers. The notation introduced in Eq. (35) is used. Arrows indicate tensors that may be replaced by others due to permutations of indices, while tensors indicated by (p#) may be replaced by others due to Eq. (B3).

| # | $\chi^{(p#)}$ | Note | $\chi^{(p#)}$ | Note |
|---|---|---|---|---|
| 1 | (333) | 35 (12113) + (21223) | $\to$ 21 |

The corresponding torque may be written as

$$t_{ij}^{\text{even}} = \Xi_{in} \left[ \sum_{\# = 1}^{7} \beta_{\#} \chi^{(p\#)}_{nj} + \sum_{\# = 8}^{68} \beta_{\#} \chi^{(p\#)}_{njklm} M_{ij} M_{km} \right] M_{k},$$

(B2)

where the matrix $\Xi$ is defined in Eq. (11). As discussed above, one may set $\beta_{\#} = 0$ for all tensors $\#$ indicated by an arrow in Table III, i.e., $\beta_{12} = 0, \beta_{13} = 0, \beta_{17} = 0, \ldots$.

Due to the relations

$$\Xi_{in}\chi_{nj} M_{k} = -\Xi_{in}\chi_{njklm} M_{ij} M_{km},$$

(B3)

we may additionally set $\beta_{\#} = 0$ in Eq. (B2) for $\#$ = 5, 27, 40, 41, 46, 49, 50, 51, 54, 55, 62, 63. Thus, there are only 6 linearly independent polar tensors of rank 3 and 12 linearly independent polar tensors of rank 5 that need to be considered in Eq. (B2), i.e., 18 tensors in total and 18 corresponding fitting parameters $\beta_{\#}$.
