We present a Lie–algebraic classification and detailed construction of the dynamical invariants, also known as Lewis–Riesenfeld invariants, of the four–level systems including two–qubit systems which are most relevant and sufficiently general for quantum control and computation. These invariants not only solve the time–dependent Schrödinger equation of four–level systems exactly but also enable the control, and hence quantum computation based on which, of four–level systems fast and beyond adiabatic regimes.

I. INTRODUCTION

Quantum computation is an emerging discipline in which quantum physics is used as a computational resource. By making use of states and operations, which have no classical counterparts, a quantum computer is expected to execute some hard tasks for a classical computer in a reasonable time. Here operations are mostly elements of SU(2^n), where n is the number of qubits, on which the operations act. It is known that any classical logic operation may be realized by a collection of the NAND gate. The corresponding “universality theorem” is due to Barenco et al.\[3\]. The theorem claims that “any unitary gate can be decomposed into one–qubit (i.e., SU(2)) gates and the CNOT gates. In other words, the set of one–qubit gates and the CNOT gate are universal in gate implementations. In many physical systems, implementation of a one–qubit gate is often not hard. It may be realized by the Rabi oscillation or the Raman transition, for example. In contrast, implementation of the CNOT gate can be challenging and its realization is sometimes regarded as a milestone for a physical system to be a true candidate of a working quantum computer.\[1\]. Later, it turned out that any SU(4) gate, which entangles a tensor product state, may serve as an element of a universal set of quantum gates with the set of one–qubit gates. Important exceptions of two–qubit gates that are excluded are the SWAP gate and the “local gates” SU(2) ⊗ SU(2).

The above observations make the importance of implementation of an SU(4) gate obvious. Adiabatic two–qubit gate implementation is limited in time by the coupling strength between the two qubits on which the gate acts. In NMR, for example, the coupling strength J is on the order of 1 ~ 100 Hz, leading to the execution time on the order of milliseconds to second, while the execution time of a one–qubit gate is limited by the strength of the RF pulse and it is typically on the order of 10 µs for a π–pulse for a heteronuclear molecule. It may take longer for a homonuclear molecule. By considering this large difference between the execution times, two–qubit gates often become a bottleneck in shortening the execution time of a whole quantum circuit. This is the motivation of considering non–adiabatic implementation of nontrivial SU(4) gates.

Furthermore, there are many nontrivial quantum algorithms, such as the Deutsch Algorithm, the Grover algorithm and the Bernstein–Vazirani algorithm, just to name a few, which can be demonstrated with a two–qubit system and an SU(4) gate. Execution of these algorithms with a speed beyond the adiabatic limit shows the promising future of a realization of quantum computing.

A. Dynamical Invariants

An alternative way of constructing solutions of the time–dependent Schrödinger equation and obtaining the time–evolution operator is by means of the eigenstates of an operator \( I = I \otimes 1 \) which is a dynamical invariant of the system with a time–independent expectation value \( \langle I \rangle \). A dynamical invariant (DI) or a Lewis–Riesenfeld Invariant (LRI) obeys

\[
\langle I \rangle = \langle \psi(t) | I | \psi(t) \rangle = \langle \psi(0) | U^\dagger U | \psi(0) \rangle = \text{const.},
\]

(1)

where \( U = U(t; 0) \) is the time evolution operator. Using Heisenberg’s equation (in units such that \( \hbar = 1 \)) we can restate this condition as

\[
0 = \frac{d}{dt} I^{(H)} = \left( \frac{\partial I}{\partial t} \right)^{(H)} + i[H^{(H)}, I^{(H)}].
\]

(2)

where the superscript \( (H) \) denotes a Heisenberg picture operator \( O^{(H)} = U^\dagger O U \), where \( O \) is a Schrödinger picture

1 We will use \( I \) to denote a dynamical invariant and \( \mathbf{1} \) to denote 2 × 2 identity matrix throughout the paper.
operator. With the LHS being 0, Eq. (2) simplifies to
\[
0 = \frac{\partial I}{\partial t} + i[H, I],
\]
which is an equation in the Schrödinger picture. We will refer to this Liouville–von Neumann type equation as the DI equation. In terms of the eigenstates of \( I \), \( |\phi_n(t)\rangle \), the general solution of the time–dependent Schrödinger equation can be written as
\[
|\Psi(t)\rangle = \sum_n c_n e^{i\alpha_n(t)} |\phi_n(t)\rangle
\]
and the time–evolution operator becomes
\[
U(t; 0) = \sum_n e^{i\alpha_n(t)} |\phi_n(t)\rangle \langle \phi_n(0)|
\]
where Lewis–Riesenfeld phase \( \alpha_n(t) \) is given as
\[
\alpha_n(t) = \int_0^t \langle \phi_n(s)| \left( i \frac{\partial}{\partial s} - H(s) \right) |\phi_n(s)\rangle \, ds.
\]
We observe that eigenstates of \( I \) evolve in the following simple form
\[
e^{i\alpha_n(t)} |\phi_n(t)\rangle = U(t; 0) |\phi_n(0)\rangle.
\]
This passage is transitionless in the eigenbasis of \( I \), and is not necessarily adiabatic. The power of DIs goes beyond solving the time–dependent Schrödinger equation however. A major problem in adiabatic quantum control is that in many cases the evolution is so slow that the system may start decohering. Evolution in the eigenstates of \( I \), however, is not restricted by the adiabaticity condition and can be made to be fast, a feature which caused a recent surge of applications. DIs have been used in the context of quantum field theory. Another attractive feature of DI is that once obtained, the time–evolution operator of the system can be constructed from its eigenvectors following Eq. (3) (which can be otherwise obtained by the direct evaluation of the time–ordered integral or through Wei–Norman expansion).

B. Quantum Control Based on DIs

Quantum control is vital to quantum computation. For example, in one of the major quantum computation schemes, the AQC, a quantum gate is essentially an adiabatic quantum control passage. Nevertheless, in general, an adiabatic control of a system is very slow relative to the decoherence of the system which may render an AQC model over the system impractical. To resolve this issue, a quantum computation scheme based on DIs has also been proposed. Nonetheless, two limitations hinder the quantum control methods and hence the quantum computation models based on DIs are not widely applicable, due to the three difficulties in obtaining a DI of a Hamiltonian.

In principle, a Hamiltonian of a system is a time–dependent operator on the Hilbert space of the system, so is a DI associated with the Hamiltonian; they satisfy the DI equation. The first two difficulties regard the operator form of the DIs of a Hamiltonian. A Hamiltonian can spawn multiple DIs, as aforementioned; hence, one must not only know all possible DIs of a Hamiltonian but also select from among them the one pertinent to the end of the control, and determine whether the choice is optimal. These difficulties worsen dramatically with the system’s level. Unfortunately, the current literature has not been able to cope with these difficulties; instead, it usually fumbles a way to certain DIs. Note that in the case of two–level, however, a classification of Hamiltonians and their DIs does exist [24, 25]. Consequently, insofar the quantum control and computation models based on DIs are nigh limited to two–level systems [24, 25]. Special cases in four–level systems have also been studied [26].

Even if the operator form of a DI is known (it may or may not belong to a subalgebra of \( \mathfrak{su}(4) \) as we detail in Section II) it is still hard to obtain the DI in closed–form by solving the DI equation, which is in fact a set of differential equations, the number of which depends on the number of degrees of freedom of the system. Besides partially causing the first limitation, this third difficulty circumscribes how and how much one can control a quantum system based on the DIs of the system. In fact, because of this limitation, in order to gain the control of a quantum system via a DI of the system, a special method—the inversely engineered control (IEC)—is needed, which was invented in [27] for pure states and extended to mixed states [28].

Although this paper is not about quantum control, so as to understand some settings for classifying DIs in the main text, let us briefly introduce the gist of quantum control, in regard of AQC and IEC. To control a quantum system one needs to expose the system in an external electromagnetic field that interacts with the system, such that the total Hamiltonian of the system and the external field evolves temporarily in the way that takes the system to a designated state at some point of time. A system under an AQC remains in an instantaneous eigenstate of the total Hamiltonian that must satisfy the adiabaticity condition, the violation of which would render the AQC of the system impossible.

In the control based on a DI of a system, however, the system does not necessarily follow any instantaneous eigenstate of the total Hamiltonian of the system and the external field but rather always stays in an instantaneous eigenstate of the DI. This idea of control is realized by the IEC method. In contrast to the logic that one should know a Hamiltonian first to determine its DIs, in IEC, one only get hold of the matrix form of a Hamiltonian, while leaving its physical parameters unknown, assume the matrix form of a DI and postulate some simple functional forms of its parameters, determine the physical parameters of the DI by the boundary conditions that comply with the wanted initial and final states of the
control, and then use the DI equation to nail down the Hamiltonian that bears this DI. In doing so, one avoids the difficulty of solving the DI equation directly from a known Hamiltonian. Aside of this mathematical advantage of IEC, a physical advantage is that the control can be done regardless of the adiabaticity condition and thus serves as a shortcut to adiabatic control. But the costs are: 1) the Hamiltonian obtained this way may be unphysical or impractical 2) a great deal of control range is lost due to the restricted postulates one can make of the parameters of the DI.

In [13] the method is demonstrated in an $su(2)$ problem. The DI is taken to be a function of the form

$$\mathcal{I} = \frac{\Omega_0}{2} \left( \sin \gamma \cos \beta \sigma_x + \sin \gamma \sin \beta \sigma_y + \cos \gamma \sigma_z \right), \quad (8)$$

where $\gamma$ and $\beta$ are polynomials in $t$ of order 3 and 4 respectively, by ansatz. The system is assumed to be prepared in a shared eigenstate of $\mathcal{I}$ and $H$ initially, and due to Eq. (7) there will not be any transitions in the eigenbasis of $\mathcal{I}$. This situation is similar to adiabatic quantum control where the passage is transitionless in Hamiltonian’s eigenbasis, but without the adiabaticity condition. The corresponding Hamiltonian is found by using the DI equation as

$$H = \frac{1}{2} \left[ \dot{\gamma} \sigma_x + \left( \dot{\beta} \cot \gamma \cos \beta - \dot{\beta} \right) \sigma_z \right]. \quad (9)$$

The coefficients of the polynomials are fixed by employing the population inversion condition at a final time $t_f$, and requiring $[H(0), I(0)] = [H(t_f), I(t_f)] = 0$ which ensures that the initial and final states are eigenstates of the Hamiltonian as well. $t_f$ can be arbitrarily small, as long as it does not violate the time–energy uncertainty relation [13, 28], resulting in a passage that can be made fast. Unfortunately, a precise implementation of the required Hamiltonian is not an easy task.

One may wonder if in IEC it is still difficult to guess the matrix form of a DI of a Hamiltonian. Indeed, it is still difficult; however, as IEC has been applied to only two–level systems so far [3], the difficulty is negligible, as one can always cast the DI in a linear combination of the three Pauli matrices, which is simple enough and without loss of generality. A four–level system has 15 generators, rendering the operator form of DI a lot more difficult to guess and resulting set of differential equations are less likely to be solved analytically. A companion paper addresses the issue by offering a Lie algebraic classification of DIs for Hermitian, finite–level systems [30]. To this end, we assume in this paper four–level Hamiltonians and their DIs live in the Lie algebra $su(4)$ as discussed in [30]. Below we list our main results.

i) We apply the key ideas addressed in [30] to four–level systems which are of particular importance in quantum computation.

ii) We show DIs of four–level systems can be classified in terms of the maximal subalgebras of $su(4)$.

iii) By means of this classification, we construct DIs for a family of four–level system, which are sufficiently general for applications.

iv) Our classification indicates a great reduction of the complexity in constructing exact DIs of four–level systems.

v) We list explicit set of differential equations for both types, and further discuss the cases which are both exactly solvable and physically feasible.

This paper is organized as follows. In the next section, we give a review of the two types of DIs and the adjoint DI equation. We move on to the classification of $su(4)$ DIs with respect to the subalgebra that spans the set of generators in the Hamiltonian in the following section, and give detailed analysis for each possible case. Finally we summarize our results. Throughout the rest of the paper, summation over repeated indices is assumed unless stated otherwise.

II. OBTAINING DYNAMICAL INVARIANTS

We summarize the relevant findings of [30] in a self–contained manner from an $su(4)$ point of view in this section. A given Hamiltonian can have infinite number of DIs. Since $I \in su(4)$ we can expand it linearly in terms of a convenient set of $su(4)$ generators $\mathcal{J}$ with time–dependent coefficients as $g^{(\lambda)}_i \lambda_i = g^{(\lambda)}_i(t) \lambda_i$. (For brevity, we will drop the superscript denoting the representation for the fundamental representation and set $g_i = g^{(\lambda)}_i$ in what follows). We assume $H \in su(4)$, since we can always drop the identity element which would otherwise commute with everything per Eq. (8) and result in the same equation. Letting $\mathcal{J}$ be the set that generates $H$ and ignoring the coefficients $i f_{ijk}$ for a moment (we use the convention in which the structure constants obey $[\lambda_i, \lambda_j] = i f_{ijk} \lambda_k$), due to Eq. (9) $\mathcal{J}$ will obey

$$\mathcal{J} = [\mathcal{J}, \mathcal{J}]^\perp. \quad (10)$$

When we choose to include any generator from the set $\mathcal{J}$ in $\mathcal{J}$, as a consequence of Cartan decomposition, $\mathcal{J}$ spans the minimal subalgebra $\mathcal{G}$ that encloses $\mathcal{J}$, with $\mathcal{J} \subseteq \mathcal{G}$, span($\mathcal{J}$) = $\mathcal{G} \subseteq su(n)$. We refer this class as $S(upperset)$–type DI, or for the purposes of this paper equivalently $S(subalgebra)$–type DI, which has been the focus in the literature so far.

Another class of DIs are generated by a completely disjoint set of generators from that of $\mathcal{J}$. As we will see in Section [31] the number of DIs obeying $\mathcal{J} \cap \mathcal{J} = \emptyset$.

---

2 In [28], where a quantum computation model based on DIs are proposed, the control method of four–level systems is essentially the same as IEC.
which we will refer as $D$-(isjoint)-type DIs, is determined by the embeddings of the subalgebras of $\mathfrak{su}(n)$, once the minimal enclosing subalgebra of $\mathfrak{h}$ is determined. Clearly when $\mathfrak{h} = \mathfrak{su}(n)$, there are no D–type DIs. We will see that in some cases, such as $\mathfrak{h} = \mathfrak{so}(5) \subset \mathfrak{su}(4)$, a D–type invariant can simplify the problem.

When we plug $I = g_i \lambda_i$ into the DI equation, we obtain

$$0 = g + i A g,$$

hereafter called the adjoint DI equation, where $g = (g_1, \ldots, g_{15})^T$ is a vector made of the expansion coefficients of $I$. At first sight, $i A$ is a $15 \times 15$ anti–symmetric, real matrix whose entries are linear combinations of the coefficients in $H$. By casting Eq. (11) into

$$0 = g_i \lambda_i + g_j [H, \lambda_j]$$

and comparing with Eq. (11), we see that the $A$ matrix can be obtained from the Hamiltonian directly as $\text{ad}(H)$. This means $A$ matrix lives in the adjoint representation of $\mathfrak{su}(4)$, that is $A \in \text{ad}[\mathfrak{su}(4)]$ in general. $A$ obtained this way will be a block diagonalized $15 \times 15$ matrix, with different blocks representing S–type and D–types (if there is any). Once the adjoint representation is known, this serves as a very practical way of obtaining $A$.

Due to the DI equation, if $I$ is a valid DI and if a Hermitean time–independent operator $A$ such that $[H, A] = 0$, then $I' = c_1 I + c_2 \mathbb{1} + c_3 A$ where $\{c_i\}$ are constants is also a valid DI. This freedom allows one to work with a “minimal” DI in which the time–independent trace part and terms that commute with $\mathfrak{h}$ are dropped. We will exploit this freedom in what follows, and work with this kind of minimal DIs. We remark that since $I$ obeys the same Liouville–von Neumann equation just like the density matrix $\rho$, it is possible to obtain a density matrix from a DI vice versa, some examples given in `[31, 32]`. Traceless part of $\rho$ is always a valid DI, but the converse is not true. A density matrix has trace one and is positive semi–definitive whereas a DI is not necessarily, however this situation may be remedied using a “non–minimal” DI when necessary.

### III. FOUR–LEVEL SYSTEMS

In this paper, we will be working with a form of four–level Hamiltonian which is generic enough to cover almost all practical applications\(^\text{3}\)

$$J_i \sigma_i \otimes \sigma_i + h_i^{(1)} \sigma_i \otimes \mathbb{1} + h_i^{(2)} \mathbb{1} \otimes \sigma_i \quad (i = x, y, z)$$

with at least one non–zero $J_i$. Each $J_i$ is a coupling coefficient, and each $h_i^{(1)}$ ($h_i^{(2)}$) is a field acting on the first (second) qubit, and is sometimes referred to as a control parameter. There could be an extra term $\mathbb{1} \otimes \mathbb{1}$ in the Hamiltonian which we deliberately dropped; it would commute with everything else and would not appear in the adjoint DI equation. We will choose to drop any generator that commutes with all the others for the same reason. For purposes of quantum control we prefer to work with a representation involving elements of the form $\{\sigma_i \otimes \mathbb{1}, \mathbb{1} \otimes \sigma_i, \sigma_i \otimes \sigma_i\}$ which allows us to read off the physical content directly. Moreover, this representation is compatible with the spinor representation of $\mathfrak{so}(4)$ and $\mathfrak{so}(5)$, and will be referred as such from here on. Another advantage of this spinor basis is that the commutator of two spinor elements is never a linear combination of more than one generators, which lets us use Eq. (10) smoothly. We will use the shorthand notation $XY$ to denote $\sigma_x \otimes \sigma_y$ interchangeably throughout the paper.

The $A$ matrix corresponding to the subalgebra (S–type) and disjoint (D–type, may or may not exists) cases can be read off directly as separate blocks after block–diagonalization, in which case $g$ belongs to one of the two subspaces that correspond to two distinct DIs. There can be more than one S–type or D–type DIs which will cause further block diagonalization in the respective sector. The overall block structure and the algebraic structure are determined through the embedding of the corresponding subalgebra of the adjoint representation which is the 15 dimensional representation of $\mathfrak{su}(4)$ in our case. Possible group embeddings are listed in Table II.

| $\mathfrak{su}(3) \oplus \mathfrak{u}(1)$ | $3\sigma_3 + 3\sigma_1 + 1\sigma_0 + 8\sigma_0$ |
| $\mathfrak{so}(4)$ | $(3, 1) + (1, 3) + (3, 3)$ |
| $\mathfrak{so}(4) \oplus \mathfrak{u}(1)$ | $(1, 1) + (3, 1) + (1, 3) + (2, 2) + (2, 2) + 5 + 10$ |

### TABLE I. Maximal subalgebras of $\mathfrak{su}(4)$ in the adjoint representation\(^\text{34}\).

In this paper, we will be working with a form of four–level Hamiltonian which is generic enough to cover almost all practical applications\(^\text{3}\)

\[ J_i \sigma_i \otimes \sigma_i + h_i^{(1)} \sigma_i \otimes \mathbb{1} + h_i^{(2)} \mathbb{1} \otimes \sigma_i \quad (i = x, y, z) \]

with at least one non–zero $J_i$. Each $J_i$ is a coupling coefficient, and each $h_i^{(1)}$ ($h_i^{(2)}$) is a field acting on the first (second) qubit, and is sometimes referred to as a control parameter. There could be an extra term $\mathbb{1} \otimes \mathbb{1}$ in the Hamiltonian which we deliberately dropped; it would commute with everything else and would not appear in the adjoint DI equation. We will choose to drop any generator that commutes with all the others for the same reason. For purposes of quantum control we prefer to work with a representation involving elements of the form $\{\sigma_i \otimes \mathbb{1}, \mathbb{1} \otimes \sigma_i, \sigma_i \otimes \sigma_i\}$ which allows us to read off the physical content directly. Moreover, this representation is compatible with the spinor representation of $\mathfrak{so}(4)$ and $\mathfrak{so}(5)$, and will be referred as such from here on. Another advantage of this spinor basis is that the commutator of two spinor elements is never a linear combination of more than one generators, which lets us use Eq. (10) smoothly. We will use the shorthand notation $XY$ to denote $\sigma_x \otimes \sigma_y$ interchangeably throughout the paper.

The $A$ matrix corresponding to the subalgebra (S–type) and disjoint (D–type, may or may not exists) cases can be read off directly as separate blocks after block–diagonalization, in which case $g$ belongs to one of the two subspaces that correspond to two distinct DIs. There can be more than one S–type or D–type DIs which will cause further block diagonalization in the respective sector. The overall block structure and the algebraic structure are determined through the embedding of the corresponding subalgebra of the adjoint representation which is the 15 dimensional representation of $\mathfrak{su}(4)$ in our case. Possible group embeddings are listed in Table II.

In this paper, we will be working with a form of four–level Hamiltonian which is generic enough to cover almost all practical applications\(^\text{3}\)

$J_i \sigma_i \otimes \sigma_i + h_i^{(1)} \sigma_i \otimes \mathbb{1} + h_i^{(2)} \mathbb{1} \otimes \sigma_i$ (i = x, y, z)

with at least one non–zero $J_i$. Each $J_i$ is a coupling coefficient, and each $h_i^{(1)}$ ($h_i^{(2)}$), is a field acting on the first
spinor basis with a particular ordering or a new set of their linear combinations. In this case, we may simply perform a time–independent similarity transformation on the adjoint DI equation: let \(\{\Sigma_i\}\) be the new basis for DI such that \(I = g_i \lambda_i = g_i^{(\Sigma)} \Sigma_i\). The transformation matrix relating two sets of generators through \(\Sigma_i = [S]_{ij} \lambda_j\) can be obtained using \(\text{tr}(\lambda_i \lambda_j) = 2 \delta_{ij}\) as \([S]_{ij} = \text{tr}(\Sigma_i \lambda_j)/\text{tr}(\lambda_i \lambda_i)\). Note that this mixes the original generators rather than transforming them altogether in the same way. The \(g\) vector will transform the same way as \(\lambda\) does, since \(g_i \lambda_i\) as a whole forms as a single “component” of \(I\), from which we deduce that the adjoint DI equation will become

\[
0 = g^{(\Sigma)} + i A^{(\Sigma)} g^{(\Sigma)}; \\
A^{(\Sigma)} = SAS^{-1}, \quad g^{(\Sigma)} = Sg.
\]

Clearly, for the differential equation

\[
0 = \frac{\partial}{\partial t} (Sg) + i (SAS^{-1})(Sg)
\]

to keep its form after the similarity transformation, we must have \((\partial S/\partial t)g = 0\), which is always the case when the new frame is stationary as in our case.

We observe that the choice of axes is not of any importance, as any similarity transformation on the set of generators as a whole leaves the subalgebra spanned by \(J\) and the structure constants intact, resulting in the same equation as above. Nevertheless, the choice of generator basis does make a difference by mixing the components of \(g\) and determining the block structure of \(A\).

## A. Classification of Hamiltonians and Invariants

Let us denote an \(S\)–type \(J\) with \(J_S\) and a \(D\)–type \(J\) with \(J_D\). Given a Hamiltonian, the subalgebra spanned by \(J_S\) can be determined directly by means of Table II. When \(|\delta| \leq 3\), due to the simplicity, one can manually check whether these generators belong to an \(su(2)\). In other cases, finding the smallest set in the table such that \(J\) fits into gives the answer. However, we can alternatively decide on the desired subalgebra as our starting point and pick a subset of corresponding generators from the table to form a Hamiltonian, which will be our approach in this paper to exhaust all possibilities in a concise way.

Depending on the list of generators appearing in \(J_S\), further embeddings are possible through the embedding of the subgroups listed in Table II. Note that \(so(4) \subset su(4)\) and \(so(4) \subset so(4) \oplus u(1) \subset su(4)\) will result in different \(D\)–types and different block structures for \(A\). The block structure is dictated by the maximal embedding.

---

4 Because there is no standard ordering for the spinor basis and we will need to use different orderings later on, we do not list the structure constants for them.

5 Although the physical context is different, [51] studies an \(so(4)\) Hamiltonian in a Lie–algebraic framework.

---

| Table II. List of maximal (semi–)simple subalgebras \(\mathfrak{g} \subset su(4)\) when \(\delta \subseteq \{\sigma, \mathbb{I}, \sigma_\alpha, \sigma_\alpha \vee, \sigma_\beta, \sigma_\beta \vee, \sigma_\gamma, \sigma_\gamma \vee\}\) with at least one \(\sigma_\alpha\)–type generator, in accordance with Eq. (13). There is no summation over repeated indices. The indices \(i, j, k \in \{x, y, z\}\) are distinct. \(\sigma_\alpha\) serves as a wildcard in such a way that \(\sigma_\alpha \sigma_\alpha\) denotes three elements \(\sigma_\alpha \sigma_\alpha \sigma_\alpha \sigma_\alpha\). The complementary table is obtained by swapping the role of first and second terms in all generators. Alternative tables can be obtained by similarity transformations. Tensor product symbol is omitted for brevity. The table is referred and used in Section III.B.1. |
|---|
| \(su(3) \oplus u(1)\) | – |
| \(so(4)\) | \(\{\sigma, \sigma_\alpha, \sigma_\beta, \sigma_\gamma, \mathbb{I}, \sigma_\alpha \mathbb{I}, \sigma_\beta \mathbb{I}, \sigma_\gamma \mathbb{I}, \mathbb{I} \sigma_\alpha, \mathbb{I} \sigma_\beta, \mathbb{I} \sigma_\gamma\}\). |
| \(so(4) \oplus u(1)\) | \(\{\mathbb{I}, \sigma_\alpha, \sigma_\beta, \sigma_\gamma\} \cup \{\sigma, \mathbb{I}\}, \{\mathbb{I}, \sigma_\alpha, \sigma_\beta, \sigma_\gamma, \mathbb{I} \}, \{\mathbb{I}, \sigma_\alpha, \sigma_\beta, \sigma_\gamma\} \cup \{\sigma, \mathbb{I}\}\}. |
| \(so(5)\) | \(\{\mathbb{I}, \sigma_\alpha, \sigma_\beta, \sigma_\gamma\}\). |

---

B. Exact Dynamical Invariants

The adjoint DI equation for the \(su(2) \cong so(3)\) case has been studied in the literature extensively under different contexts, with many known exactly solvable cases, and is known as the Bloch equation with infinite relaxation. Thus the Bloch equation is a special case of the adjoint DI equation.

In both \(so(4) \cong su(2) \oplus su(2)\) and \(so(4) \oplus u(1)\) cases we essentially have two decoupled Bloch equations, meaning that the mathematical problem reduces to solving single–qubit problems. Note that the two physical qubits are actually coupled in \(so(4) \oplus u(1)\) case but not in \(so(4)\) case. The explicit block diagonalization to bring \((3, 1) + (1, 3)\) into \((3, 3)\) can be achieved by a time–independent similarity transformation. To this purpose, we first notice that \(so(4)\) is readily split into two distinct \(su(2)\)’s \(\{\mathbb{I}, \sigma_\alpha\} \cup \{\mathbb{I}, \sigma_\beta\}\) (note that some generators may require a correction of sign depending \(\{i, j, k\}\) being an odd permutation of \(\{x, y, z\}\) or not). Clearly, such a Hamiltonian represents composite systems with two non–interacting \(su(2)\) subsystems. The other \(so(4)\) case \(\{\mathbb{I}, \sigma_j, \mathbb{I} \sigma_k, \mathbb{I} \sigma_k\} \cup \{\mathbb{I} \sigma_k, \mathbb{I} \sigma_j, \mathbb{I} \sigma_j\}\) is equivalent to the former case up to a similarity transformation. Moreover, the \(D\)–type DI for \(so(4)\) results in a \(9 \times 9\) matrix, which does not help simplifying the problem. It is because of these facts that we will not analyze \(so(4)\) subalgebra any further.
in the notation and order of Table III. Note that the summands in each new generator are related to each other by the $u(1)$ generator of the subalgebra; we have exploited the following to obtain these pairs: let $\{ T_1, T_2, T_3 \} \cup q$ (where $\{ T_1, T_2, T_3 \} \subset J_S$ and $q^2 = 1$) be an $su(2) \oplus u(1)$, then $\{ T_1 \pm qT_1, T_2 \pm qT_2, T_3 \pm qT_3 \}/2$ is a pair of $su(2)$ and $\{ T_1, T_2, T_3, qT_1, qT_2, qT_3 \} \cup \{ q \}$ is an $so(4) \oplus u(1)$. Different choices such as the one given in (22) can be obtained through time–independent similarity transformations. Furthermore, the sector corresponding to the D–type DI further splits into two $4 \times 4$ blocks in $so(4) \oplus u(1)$, resulting in four smaller, decoupled adjoint DI equations. These two sets of 4 generators are conjugate of each other under the respective $u(1)$ generator. There are three types of $so(4) \oplus u(1)$ (see Table III) which we will discuss in detail below.

I. $so(4) \oplus u(1)$

1. This first case is also known as single-qubit control Ising model, and the corresponding Hamiltonian can be written as

$$H = JXX + h_x I X + h_y I Y + h_z I Z.$$  

(17)

A quick comparison of the set of generators $:\mathcal{F} = \{ I X, I Y, I Z, X X, X Y, X Z \} \cup \{ I I \} \cup \{ X I, X Y, X Z, -Z I \}$ (18) reveals span($\mathcal{F}$) $\subset$ $so(4) \oplus u(1)$ (the first entry in the table, due to the distinctive control terms $\sigma_x$, along with $\sigma_z$), with the algebraic groupings given as

$$\{ \Sigma_i \} = \{ I I, I Y, I Z, X X, X Y, X Z \} \cup \{ X I \} \cup \{ X I, X Y, X Z, -Z I \}$$

$$= J_S \cup Q \cup J_D \cup \mathcal{J}_D.$$  

(19)

The sets $J_D$ and $J_D$ representing two D–type invariants obey Eq. (10), and are related to each other by an infinitesimal $u(1)$ charge conjugation

$$[Q, J_D] = -2iJ_D, \quad [Q, J_D] = 2iJ_D.$$  

(19)

Exploiting the $u(1)$ factor of the subalgebra, it is possible to consider an additional time–dependent $XI$ term in the Hamiltonian as well, but it will not affect the discussion that follows. Although the $(3,1) + (1,3)$ $so(4)$ sector is not two readily decoupled $su(2)$ systems, such a situation can always be remedied by means of a time–independent similarity transformation which we will employ below. This is of course not the case for the $(2,2)_{\pm 2}$ sector.

In the generator basis $\{ \Sigma_i \}$ the adjoint DI equation is

$$0 = \dot{g}^{(2)} + iA^{(2)} g^{(2)}$$

and $A^{(2)}$ has the block diagonal form

$$A^{(2)} = A^{(2)}_{(3,1)+(1,3)} \oplus (0) \oplus A^{(2)}_{(2,2)_{-2}} \oplus A^{(2)}_{(2,2)_{+2}}$$

where

$$A^{(2)}_{(3,1)+(1,3)} = 2i \begin{pmatrix} 0 & -h_x & h_y & 0 & 0 & 0 \\ h_x & 0 & -h_x & 0 & 0 & -J \\ -h_y & h_x & 0 & 0 & J & 0 \\ 0 & 0 & 0 & -h_z & h_y & 0 \\ 0 & 0 & -J & h_z & 0 & -h_x \\ 0 & J & 0 & -h_y & h_x & 0 \end{pmatrix},$$

$$A^{(2)}_{(2,2)_{-2}} = 2i \begin{pmatrix} 0 & -h_z & h_y & 0 & 0 & 0 \\ h_z & 0 & -h_x & 0 & 0 & -J \\ -h_y & h_x & 0 & 0 & J & 0 \end{pmatrix}.$$  

(20)

and $(0)$ is a $1 \times 1$ matrix containing $0$. The corresponding linear combinations of $so(4)$ generators listed in Eq. (10) are the two independent sets of $su(2)$, $\{ \Sigma^{\pm} \} = \{ (I \pm X)Y, (I \pm X)Y, (I \pm X)Y \}/2$. Transforming to the basis $\{ \Sigma^{\pm} \} = \{ \Sigma^{+} \} \cup \{ \Sigma^{-} \}$ by employing Eq. (14) with $[S]_{ij} = \text{tr}(\Sigma^{+}_i \Sigma^{-}_j)/4$,

$$S = \frac{1}{2} \begin{pmatrix} 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & -1 & 0 & 0 \\ 0 & 1 & 0 & 0 & -1 & 0 \\ 0 & 0 & 1 & 0 & 0 & -1 \end{pmatrix}$$  

(21)

will block diagonalize $A^{(2)}_{(3,1)+(1,3)}$, yielding

$$0 = \dot{g}^{\pm} + iA^{\pm} g^{\pm}$$  

(22)

where

$$A^{\pm} = -2i \begin{pmatrix} 0 & -h_z & h_y & 0 & 0 & 0 \\ h_z & 0 & -h_x & 0 & 0 & -J \\ -h_y & h_x & 0 & 0 & J & 0 \end{pmatrix},$$  

(23)

$$g^{\pm} = (g_{II} \pm g_{XX}; g_{YY} \pm g_{XY}; g_{ZZ} \pm g_{XZ})/2.$$  

2. The second type of Hamiltonian in $so(4) \oplus u(1)$ can be written as

$$H = JXX + h^{(1)} Y I + h^{(2)} Z I.$$  

(24)

Generators of the S–type, its respective $u(1)$ generator as well as the generators of the D–types are grouped as

$$\{ \Sigma_i \} = \{ XX, Y I, ZX, ZY, I Z, I Z, X Y, Y X \} \cup \{ Y Z \} \cup \{ X I, Z I, Y I, Y X \} \cup \{ Z Z, -X Z, X I, X \} \cup \{ I I \}.$$  

(25)

Taking the adjoint $A^{(2)} = \text{ad}(H)$, we obtain $A^{(2)}_{(3,1)+(1,3)}$
(0) ⊕ \( A^{(\Sigma)}_{(2,2)_{-2}} \oplus A^{(\Sigma)}_{(2,2)_2} \),

\[
A^{(\Sigma)}_{(3,1)+(1,3)} = 2i \begin{pmatrix}
0 & 0 & h_y^{(2)} & 0 & 0 & -h_z^{(1)} \\
0 & 0 & -J_x & 0 & 0 & 0 \\
-h_y^{(2)} & J_x & 0 & -h_z^{(1)} & 0 & 0 \\
0 & 0 & h_z^{(1)} & 0 & 0 & -h_y^{(2)} \\
0 & 0 & 0 & 0 & 0 & J_x \\
h_z^{(1)} & 0 & 0 & h_y^{(2)} & -J_x & 0
\end{pmatrix} \tag{26}
\]

Similar to the previous case, we note that \( \{XX \pm ZY, Y \mathbb{1} \pm \mathbb{1} Z, ZX \mp XY\}/2 \) generates an \( \mathfrak{su}(2) \) algebra which enables us to further block diagonalize \( A^{(\Sigma)}_{(3,1)+(1,3)} \) into

\[
A^{\pm} = 2i \begin{pmatrix}
0 & 0 & h_y^{(2)} \pm h_z^{(1)} \\
0 & 0 & -(h_y^{(2)} \pm h_z^{(1)}) & J_x & 0 \\
0 & -J_x & -h_z^{(1)} & 0 & 0
\end{pmatrix}, \tag{27}
\]

with

\[
g^{\pm} = (g_{xx} \pm g_{zy}, g_y \mathbb{1} \pm g_{1z}, g_{zx} \mp g_{xy})^T/2. \tag{28}
\]

3. Finally, we consider the Hamiltonian

\[
H = J_x XX + J_y YY + h^{(1)} Z \mathbb{1} + h^{(2)} \mathbb{1} Z. \tag{29}
\]

which is the last instance of the \( \mathfrak{so}(4) \oplus \mathfrak{u}(1) \) listed in Table II. This Hamiltonian can implement a two-qubit gate because it can represent Josephson junctions when one of the coupling terms \( J_i \) vanishes \[52\]; also with the addition of the \( \mathfrak{u}(1) \) generator \( ZZ \) and the assumption \( J_x = J_y = J_z \), the Hamiltonian can implement \( D_3 \) model \[53, 54\] and quantum dots \[55\].

The generators are grouped as

\[
\{\Sigma_i\} = \{XX, YY, ZZ, ZY, XY, XZ, YZ, YZ, ZY, ZY\} \sqcup \{ZZ\} \sqcup \{YZ, YZ, XZ, \mathbb{1} Z\} \sqcup \{XZ, ZY, ZZ, X\mathbb{1}, \mathbb{1} Y\} \tag{30}
\]

and \( A^{(\Sigma)} \) is \( A^{(\Sigma)}_{(3,1)+(1,3)} \oplus (0) \oplus A^{(\Sigma)}_{(2,2)_{-2}} \oplus A^{(\Sigma)}_{(2,2)_2} \) where

\[
A^{(\Sigma)}_{(3,1)+(1,3)} = 2i \begin{pmatrix}
0 & -h^{(1)} & 0 & 0 & -h^{(2)} & 0 \\
h^{(1)} & 0 & -J_x & -h^{(2)} & 0 & J_y \\
0 & J_x & 0 & 0 & -J_y & 0 \\
h^{(2)} & 0 & J_y & -h^{(1)} & 0 & -J_x \\
0 & -J_y & 0 & 0 & J_x & 0
\end{pmatrix} \tag{31}
\]

\[
A^{(\Sigma)}_{(2,2)_{-2}} = 2i \begin{pmatrix}
0 & 0 & h^{(1)} & -J_y \\
0 & 0 & -J_x & h^{(2)} \\
-h^{(1)} & J_x & 0 & 0 \\
J_y & -h^{(2)} & 0 & 0
\end{pmatrix}, \tag{32}
\]

2. \( \mathfrak{so}(5) \)

We now turn to the most general \( \mathfrak{so}(5) \) case of the Hamiltonian Eq. (13), which also is the last case in Table II.

\[
H = J_x XX + J_y YY + h^{(2)} \mathbb{1} X + h^{(1)} h^{(2)} \mathbb{1} Y + h^{(2)} \mathbb{1} Z + h^{(1)} \mathbb{1} Z \tag{33}
\]

This time, the generators are grouped into two sets per Table II.\[56\]

\[
\{\Sigma\} = \{\mathbb{1}, \mathbb{1} Y, \mathbb{1} Z, XX, XY, YX, YY, XZ, YZ, ZY, ZZ\} \sqcup \{ZZ, ZY, ZZ, X\mathbb{1}, \mathbb{1} Y\} \tag{34}
\]

\( A^{(\Sigma)} \) matrix is a direct sum of two blocks \( A^{(\Sigma)}_{10} \oplus A^{(\Sigma)}_{5} \), where
This is an example case where a D–type DI greatly simplifies the problem. We further observe that there are two blocks in $A^{(2)}_{10}$ which are “coupled” to each other through $J_x$ and $J_y$. The first block is a Bloch equation similar to Eq. (23), whereas the second block is solved by

$$A^{(2)}_{10} = i \begin{pmatrix} 0 & -h_z^{(2)} & h_y^{(2)} & 0 & 0 & 0 & 0 & J_x & 0 \\ h_z^{(2)} & 0 & -h_x^{(2)} & 0 & 0 & -J_x & 0 & 0 & 0 \\ -h_y^{(2)} & h_x^{(2)} & 0 & 0 & J_x & 0 & -J_y & 0 & 0 \\ 0 & 0 & 0 & 0 & -h_z^{(2)} & h_y^{(2)} & -h_z^{(2)} & 0 & 0 \\ -h_z^{(2)} & h_x^{(2)} & 0 & 0 & 0 & -h_z^{(2)} & h_y^{(2)} & -J_x & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -J_y & 0 & 0 & 0 & 0 & h_z^{(1)} & -h_y^{(2)} & h_x^{(2)} & 0 \\ 0 & 0 & 0 & 0 & -J_y & 0 & J_x & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$  

(35)

This feature can be exploited in construction of perturbative solutions in the weak–coupling limit.

C. Solutions of the Bloch Equation

We have encountered $A \in \mathfrak{so}(3)$ for $J_S \in \mathfrak{so}(4) \oplus \mathfrak{u}(1)$ in Eqs. (23), (27), and (28). Such a matrix lives in the adjoint representation of $\mathfrak{su}(2)$, as a result we can find a two–level Hamiltonian satisfying $A^\dagger = \text{ad}(H^\perp)$, meaning we have effectively reduced four–level problems with $H \in \mathfrak{so}(4)$ and $\mathfrak{so}(4) \oplus \mathfrak{u}(1)$ into a pair of independent two–level problems, associated with the Hamiltonian $H^\perp = (h_x \pm J)\sigma_x + h_y\sigma_y + h_z\sigma_z$ for Eq. (23). (see Table III).

For the special case of Eq. (23) with $h_x = \text{const.}$, $h_y = B \cos \omega t$, $h_z = B \sin \omega t$ where $B$ and $\omega$ are time–independent, the Hamiltonian Eq. (14) becomes the NMR Hamiltonian in rotating–frame, and the problem has a simple exact solution $g^\perp = (\pm J + h_x - \omega/2, B \cos \omega t, B \sin \omega t)^T$ such that we obtain

$$I_S^\perp = (\pm J + [h_x - \omega/2])([\mathbb{1} \pm X]|X) + B \cos \omega t([\mathbb{1} \pm X]|Y) + B \sin \omega t([\mathbb{1} \pm X]|Z).$$  

(37)

We note that the Hamiltonian and the invariant are both periodic with $T = 2\pi/\omega$ and thus can be used to obtain cyclic non–adiabatic geometric phases [54, 57]. The un-normalized eigenvectors and eigenvalues of a simpler DI

$$I_S = I_S^\perp + I_S^\parallel = 2JXX + (2h_x - \omega)X + 2B \cos \omega t Y + 2B \sin \omega t Z$$  

(38)

follow as

$$|\phi^\pm_+ \rangle = i(g_2^* \pm ig_1^*) \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} + (g_3^* \pm g^*) \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix},$$  

(39)

$$\lambda_+^\pm = \pm g^+;$$

$$|\phi^\pm_- \rangle = i(g_2^* \pm ig_1^*) \begin{pmatrix} -1 \\ 0 \\ 0 \end{pmatrix} + (g_3^* \pm g^-) \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix},$$  

(39)

$$\lambda_-^\pm = \pm g^-$$

where $g^\pm = |g^\pm|$. Using these eigenvectors in Eq. (35), we can obtain the analytic time–evolution operator of the system. It would be straightforward to design quantum control of such systems accordingly.

Finally, the type of Bloch equations that appeared in Eq. (27) and Eq. (28) has several exact solutions [43] corresponding to experimentally realizable fields. When the time–dependent term is periodic and is much greater that the time–dependent part (weak–coupling limit), a perturbative solution can be constructed [44].

IV. DISCUSSION AND OUTLOOK

In this work we offered a Lie–algebraic classification and construction of DIs of four–level systems. Such systems cover two–qubit systems which are relevant and essential for quantum computation. Applications of DIs
TABLE IV. $\lambda$ matrices, obeying $\text{tr}(\lambda_i\lambda_j) = 2\delta_{ij}$. $\lambda_{1-3}$ is an $\mathfrak{su}(2)$ and $\lambda_{1-8}$ is an $\mathfrak{su}(3)$. $\lambda_8$ commutes with $\lambda_{1-3}$, $\lambda_{13}$ commutes with $\lambda_{1-8}$, giving rise to $\mathfrak{su}(2) \oplus u(1)$ and $\mathfrak{su}(3) \oplus u(1)$ subalgebras.

\begin{align*}
\lambda_1 &= \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, & \lambda_2 &= \begin{pmatrix} 0 & -i & 0 & 0 \\ i & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, & \lambda_3 &= \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, & \lambda_4 &= \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, & \lambda_5 &= \begin{pmatrix} 0 & 0 & i & 0 \\ 0 & 0 & 0 & 0 \\ i & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \\
\lambda_6 &= \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, & \lambda_7 &= \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & -i & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, & \lambda_8 &= \frac{1}{\sqrt{6}} \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 2 \end{pmatrix}, & \lambda_9 &= \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}, & \lambda_{10} &= \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ i & 0 & 0 & 0 \end{pmatrix}, \\
\lambda_{11} &= \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}, & \lambda_{12} &= \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & i & 0 & 0 \end{pmatrix}, & \lambda_{13} &= \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix}, & \lambda_{14} &= \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & i \end{pmatrix}, & \lambda_{15} &= \frac{1}{\sqrt{6}} \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -3 \end{pmatrix}.
\end{align*}

TABLE III. Adjoint representation of $\mathfrak{su}(2)$, $[\text{ad}(\sigma_i)]_{jk} = -i(\sigma_j)_{ik}$ where $[\sigma_i, \sigma_j] = if_{ijk}\sigma_k$.

\begin{align*}
\text{ad}(\sigma_x) &= 2i \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}, & \text{ad}(\sigma_y) &= 2i \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{pmatrix}, \\
\text{ad}(\sigma_z) &= 2i \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\end{align*}

Various control of four-level systems. In an ongoing work to be reported elsewhere, we try to devise a CNOT gate as a control passage based on the DIs constructed in this paper.

Appendix A: No $\mathfrak{su}(3)$ S–Type DIs

The fundamental representation of $\mathfrak{su}(4)$ is 15 Hermitian set of $\{\lambda_j\}$ matrices (Tables IV and V). The first 8 of these, along with $\lambda_{15}$ which commutes with the rest form the $\mathfrak{su}(3) \oplus u(1)$ subalgebra. They are related to spinor generators as

\begin{align*}
2\lambda_1 &= (\mathbb{1} + Z)X, & 2\lambda_2 &= (\mathbb{1} + Z)Y, \\
2\lambda_3 &= (\mathbb{1} + Z)Z, & 2\lambda_4 &= X(\mathbb{1} + Z), \\
2\lambda_5 &= Y(\mathbb{1} + Z), & 2\lambda_6 &= XX + YY, \\
2\lambda_7 &= YX - XY, & 2\sqrt{3}\lambda_8 &= 2Z\mathbb{1} - \mathbb{1}Z + ZZ, \\
\sqrt{6}\lambda_{15} &= Z\mathbb{1} + \mathbb{1}Z - ZZ.
\end{align*}

$2H$ written in terms of $\lambda_j$ is

\begin{align*}
h_{y}^{(2)}\lambda_1 + h_{y}^{(2)}\lambda_2 + (h_{z}^{(2)} + J_z)\lambda_3 + h_{y}^{(1)}\lambda_4 + h_{y}^{(1)}\lambda_5 + (J_x + J_y)\lambda_6 + \frac{2h_{z}^{(1)} - h_{z}^{(2)} + J_z}{\sqrt{3}} \lambda_8 + (J_x - J_y)\lambda_9 + h_{y}^{(1)}\lambda_{11} + h_{y}^{(1)}\lambda_{12} + h_{z}^{(2)}\lambda_{13} + h_{y}^{(2)}\lambda_{14} + \frac{2}{\sqrt{3}}(h_{z}^{(1)} + h_{z}^{(2)} - J_z)\lambda_{15} \\
&= \frac{2}{\sqrt{3}}(h_{z}^{(1)} + h_{z}^{(2)} - J_z)\lambda_{15}, \quad \text{(A2)}
\end{align*}

We see that in order to get rid of $\lambda_{9-14}$ terms, we must have $h_{z}^{(1)} = h_{y}^{(1)} = h_{z}^{(2)} = h_{y}^{(2)} = 0$ and $J_x = J_y$. This,
TABLE V. Structure constants for $\lambda$ matrices.

\begin{equation}
\langle h_z^{(2)} + J_z \rangle \lambda_3 + 2J \lambda_6 + \frac{2h_z^{(1)} - h_z^{(2)} + J_z}{\sqrt{3}} \lambda_9 + \frac{2}{\sqrt{3}} (h_z^{(1)} + h_z^{(2)} - J_z) \lambda_{15}, \tag{A3}
\end{equation}

where we defined $J = J_z = J_y$. The coefficients are linearly independent but the set of generators belong to $su(2) \oplus u(1) \subset su(3) \oplus u(1)$, from which we conclude that one cannot emulate and gain the full SU(3) control of a qutrit using two qubits with a Hamiltonian of the form \text{(19)}.
