On Opinion Dynamics in Heterogeneous Networks

Anahita Mirtabatabaei Francesco Bullo

Abstract—This paper studies the opinion dynamics model recently introduced by Hegselmann and Krause: each agent in a group maintains a real number describing its opinion; and each agent updates its opinion by averaging all other opinions that are within some given confidence range. The confidence ranges are distinct for each agent. This heterogeneity and state-dependent topology leads to poorly-understood complex dynamic behavior. We classify the agents via their interconnection topology and, accordingly, compute the equilibria of the system. We conjecture that any trajectory of this model eventually converges to a steady state under fixed topology. To establish this conjecture, we derive two novel sufficient conditions: both conditions guarantee convergence and constant topology for infinite time, while one condition also guarantees monotonicity of the convergence. In the evolution under fixed topology for infinite time, we define leader groups that determine the followers’ rate and direction of convergence.

I. INTRODUCTION

“Any social behavior can be viewed both as independent and dependent, as cause and effect” [7]. In a society, the impacts of individuals opinions on each form a network, and as the time progresses, the opinions change as a function of such network’s structure. Much research is done on how the topological properties of the interconnection network can effect final decisions. The study of opinion dynamics and social networks goes back to J.R.P. French [6]. French’s Formal Theory of Social Power explores the patterns of interpersonal relations and agreements that can explain the influence process in groups of agents. Later F. Harary provided a necessary and sufficient condition to reach a consensus in French’s model of power networks [7]. Besides sociology, opinion dynamics is also of interest in politics, as in voting prediction [11]; physics, as in spinning particles [2]; cultural studies, as in language change [17]; and economics, as in price change [16].

An important step in modeling agents in economics has been switching from perfectly rational agents approach to a bounded rational, heterogeneous agents using rule of thumb strategy under bounded confidence. There is no trade in a world where all agents are perfectly rational, which is in contrast with the high daily trading volume. Having bounded confidence in a society, which accounts for homophily, means that an agent only interacts with those whose opinion is close to its own. Mathematical models of opinion dynamics under bounded confidence have been presented independently by: Hegselmann and Krause (HK model), where agents synchronously update their opinions by averaging all opinions in their confidence bound [8], and by Deffuant and Weisbuch and others (DW model), where agents follow a pairwise-sequential updating procedure in averaging [13]. HK and DW models can be classified into either agent-based and density-based models, if the number of agents is finite or infinite, respectively; or into heterogeneous and homogeneous models, if the confidence bounds are uniform or agent-dependent, respectively. The convergence of both agent- and density-based homogeneous HK models are discussed in [3]. The agent-based homogeneous HK system is proved to reach a fixed state in finite time [5], the time complexity of this convergence is discussed in [13], its stabilization theorem is given in [9], and its rate of convergence to a global consensus is studied in [15]. The heterogeneous HK model is studied by Lorenz, who reformulated the HK dynamics as an interactive Markov chain [10] and analyzed the effects of heterogeneous confidence bounds [12]. In this paper, we focus on discrete-time agent-based heterogeneous HK (htHK) model of opinion dynamics, whose dynamics is considerably more complex than the homogeneous case. The convergence of this model is experimentally observed, but its proof is still an open problem.

As a first contribution, based on extensive numerical evidence, we conjecture that there exists a finite time along any htHK trajectory, after which the topology of the interconnection network remains unchanged, and hence the trajectory converges to a steady state. We partly prove our conjecture: (1) We design a classification of agents in the htHK system, which is a function of state-dependent interconnection topology; (2) We introduce the new notion of final value at constant topology, characterize its properties, including required condition for this value to be an equilibrium vector, and formulate the map under which final value at constant topology is an image of current opinion vector; (3) For each equilibrium opinion vector, we define its equi-topology neighborhood and invariant equi-topology neighborhood. We show that if a trajectory enters the invariant equi-topology neighborhood of an equilibrium, then it remains confined to its equi-topology neighborhood and sustains an interconnection topology equal to that of the equilibrium. This fact establishes a novel and simple sufficient condition under which the trajectory converges to a steady state, and the topology of the interconnection network remains unchanged. (4) We define a rate of convergence as a function of final value at constant topology. Based on the direction of convergence and the defined rate, we derive a sufficient condition under which the trajectory monotonically converges to a steady state, and the topology of the interconnection network remains unchanged. (5) We explore some interesting behavior of classes of agents when they update their opinions under fixed interconnection topology for infinite time, for instance, the existence of a leader group for each agent that determines the follower’s rate and direction of convergence.

This paper is organized as follows. The mathematical model, conjecture, agents classification, and equilibria are discussed in Section [II]. The two sufficient conditions for convergence and the analysis of the evolution under fixed topology are presented in Section [III]. Conclusion and future work are given in Section [IV]. Finally, the Appendix contains some proofs.

II. HETEROGENEOUS HK MODEL

Given the confidence bounds \( r = \{r_1, \ldots, r_n\} \in \mathbb{R}^n_{>0} \), we associate to each opinion vector \( x(t) = y \in \mathbb{R}^n \) the proximity digraph \( G_r(y) \) with nodes \( \{1, \ldots, n\} \) and edge set defined as follows: the set of out-neighbors of node \( i \) is \( N_i(y) = \{j \in \{1, \ldots, n\} : |y_i - y_j| \leq r_i\} \). The heterogeneous HK model of opinion dynamics updates \( x(t) \) according to

\[
x(t + 1) = A(x(t))x(t),
\]

where, denoting the cardinality of \( N_i(y) \) by \( |N_i(y)| \), the \( i, j \) entry of \( A(x(t)) = y \) is defined by

\[
a_{ij}(y) = \begin{cases} 
\frac{1}{|N_i(y)|}, & \text{if } j \in N_i(y), \\
0, & \text{if } j \notin N_i(y).
\end{cases}
\]

Conjecture II.1 (Constant-topology in finite time). It is conjectured that along every trajectory in an htHK system (1), there exists a finite time \( \tau \) after which the state-dependent interconnection topology remains constant or, equivalently, \( G_r(x(t)) = G_r(x(\tau)) \) for all \( t \geq \tau \).

This conjecture is supported by the extensive numerical results presented in [14, Section 5]. Here, let us quote some relevant definitions from the graph theory, e.g. see [4]. In a digraph, if there exists a directed path from node \( i \) to node \( j \), then \( i \) is a predecessor of \( j \), and \( j \) is a successor of \( i \). A node of a digraph is globally reachable if it can be reached from any other node by traversing a directed path. A digraph is strongly connected if every node is globally reachable. A digraph is weakly connected if replacing all of its directed edges with undirected edges produces a connected undirected graph. A maximal subgraph which is strongly or weakly connected forms a strongly connected component (SCC) or a weakly connected component (WCC), respectively. Every digraph \( G \) can be decomposed into either its SCC’s or its WCC’s. Accordingly, the condensation digraph of \( G \), denoted \( C(G) \), can be defined as follows: the nodes of \( C(G) \) are the SCC’s of \( G \), and there exists a directed edge in \( C(G) \) from node \( S_1 \) to node \( S_2 \) if and only if there exists a directed edge in \( G \) from a node of \( S_1 \) to a node of \( S_2 \). A node with out-degree zero is named a sink. Knowing that the condensation digraphs are acyclic, each WCC in \( C(G) \) is acyclic and thus has at least one sink.

A. Agents Classification

We classify the agents in an htHK system [1] based on their interaction topology at each time step. For any opinion vector \( y \in \mathbb{R}^n \), the components of \( G_r(y) \) can be classified into three classes. A closed-minded component is a complete subgraph and an SCC of \( G_r(y) \) that is a sink in \( C(G_r(y)) \). A moderate-minded component is a non-complete subgraph and an SCC of \( G_r(y) \) that is a sink in \( C(G_r(y)) \). The rest of the SCC’s in \( G_r(y) \) are called open-minded SCC’s. We define open-minded subgraph to be the remaining subgraph of \( G_r(y) \) after removing its closed and moderate-minded components and their edges. A WCC of the open-minded subgraph is called an open-minded WCC, which is composed of one or more open-minded SCC’s. The evolution and initial proximity digraph of an htHK system are illustrated in Figures 1 and 2.

Since \( C(G_r(y)) \) is an acyclic digraph, in an appropriate ordering, its adjacency matrix is lower-triangular [4]. Consequently, the adjacency matrix of \( G_r(y) \) is lower block triangular in such ordering. Following the classification of SCC’s in \( G_r(y) \), we put \( A(y) \) into canonical form \( \overline{A}(y) \), by an appropriate canonical permutation matrix \( P(y) \),

\[
\overline{A}(y) = P(y)A(y)P^T(y) = \begin{bmatrix}
C(y) & 0 & 0 \\
0 & M(y) & 0 \\
\Theta_C(y) & \Theta_M(y) & \Theta(y)
\end{bmatrix}.
\]

The submatrices \( C(y) \), \( M(y) \), and \( \Theta(y) \) are the adjacency matrices of the closed, moderate, and open-minded subgraphs respectively, and are block diagonal matrices. Each entry in \( \Theta_C(y) \) or \( \Theta_M(y) \) represents an edge from an open-minded node to a closed or moderate-minded node, respectively. The adjacency matrix \( A(y) \) is a non-negative row stochastic matrix, and its nonzero diagonal establishes its aperiodicity.

Remark 1. Previously, (Lorenz, 2006) classified the agents of the htHK systems into two classes named essential and inessential. An agent is essential if any of its successors is also a predecessor, and the rest of agents are inessential [11]. It is easy to see that closed and moderate-minded components are essential, and open-minded components are inessential.

B. Final Value at Constant Topology

Based on Conjecture II.1 for any opinion vector \( y \in \mathbb{R}^n \) we define its final value at constant topology \( \text{fvct} : \mathbb{R}^n \rightarrow \mathbb{R}^n \) to be \( \text{fvct}(y) = \lim_{t \rightarrow \infty} A(y)^t y \). Hence, if the interconnection topology of the system with initial opinion vector \( y \) remains unchanged for infinite time, the opinion vector converges to
fvct(y). Next, an opinion vector $y_0 \in \mathbb{R}^n$ is an equilibrium of the hHK system if and only if $y_0$ is an eigenvector of the adjacency matrix $A(y_0)$ for eigenvalue one or, equivalently, $y_0 = A(y_0)y_0$. The set of final values at constant topology is a superset of the equilibria. Clearly, if $y_0$ is an equilibrium, then its final value at constant topology is equal to itself, that is, fvct($y_0$) = $y_0$. The condition under which a final value at constant topology is an equilibrium of the system is discussed in Proposition III.1 for a proof of which see [14].

**Proposition II.1** (Properties of the final value at constant topology). Consider opinion vector $y \in \mathbb{R}^n$:

(i) fvct($y$) is well defined, and is equal to

$$\text{fvct}(y) = P^T(y) \begin{bmatrix} C & 0 & 0 \\ 0 & M^* & 0 \\ (I - \Theta)^{-1} \Theta_C C & (I - \Theta)^{-1} \Theta_M M^* & 0 \end{bmatrix} (y)P(y),$$

where $P(y)$ is the canonical permutation matrix, and $M^*(y) = \lim_{t \to \infty} M(y)^t$ is well defined.

(ii) If the two networks of agents with opinion vectors $y$ and fvct($y$) have the same interconnection topology, or equivalently, $G_r(y) = G_r(\text{fvct}(y))$, then

a) $\text{fvct}(y)$ is an equilibrium vector,

b) $G_r(y)$ contains no moderate-minded component, and

c) in any WCC of $G_r(\text{fvct}(y))$, the maximum and the minimum opinions $\text{fvct}_i(y)$ belong to that WCC’s closed-minded components.

**III. CONVERGENCE OF hHK SYSTEMS**

In this section, we present two sufficient conditions for hHK trajectories that guarantees fixed interconnection topology for infinite time and consequently convergence to a steady state. The second sufficient condition is more complicated and often more restrictive than the first condition, since it also guarantees the monotonicity of the convergence. Moreover, there are examples in which the first condition does not hold while the second one does, see Example III.1. We justify the second sufficient condition by studying the behavior of hHK systems under fixed topology in a long run.

**A. CONVERGENCE AND CONSTANT TOPOLOGY**

The first sufficient condition for convergence is based on agents confidence bounds. According to this condition, if an hHK trajectory enters a specific neighborhood of any equilibrium of the system, then it stays in some larger neighborhood of that equilibrium for all future iterations, and its topology remains constant. Hence, the former neighborhood is a subset of the basin of attraction for the final value at constant topology of the entering opinion vector.

**Definition III.1** (Equi-topology neighborhoods). Consider a hHK system with opinion vector $z \in \mathbb{R}^n$.

(i) Define the vector $\epsilon(z) \in \mathbb{R}^n_{\geq 0}$ with entries set equal to

$$\epsilon_i(z) = 0.5 \min_{j \in \{1, \ldots, n\} \setminus \{i\}} \{|z_i - z_j| - R| : R \in \{r_i, r_j\}\}.$$

The equi-topology neighborhood of $z$ is a set of opinion vectors $y \in \mathbb{R}^n$ such that for all $i \in \{1, \ldots, n\}$,

$$|y_i - z_i| < \epsilon_i(z), \text{ if } \epsilon_i(z) > 0, \text{ and } |y_i - z_i| = \epsilon_i(z), \text{ if } \epsilon_i(z) = 0.$$
Then the solution $G_\tau(x(t))$ to be an SCC in $\mathcal{M}(S_k(y))$ with constant topology after $[0 \ 0$.

Definition III.3 (Leader SCC). Consider an htHK system with opinion vector $y \in \mathbb{R}^n$. For any open-minded SCC of $G_r(y)$, $S_k(y)$, denote the set of its open-minded successor SCC’s by $\mathcal{M}(S_k(y))$, which includes $S_k(y)$. We define $S_k(y)$’s leader SCC to be an SCC in $\mathcal{M}(S_k(y))$ whose adjacency matrix has the largest spectral radius among all SCC’s of $\mathcal{M}(S_k(y))$.

Theorem III.4 (Evolution under constant topology). Consider an htHK trajectory $x(t)$. Assume that there exists a time $\tau$ after which $G_r(x(t))$ remains unchanged, that is, $G_r(x(t)) = G_r(x(\tau))$. Then, the following statements hold for all $t \geq \tau$:

(i) $\text{fvct}(x(t)) = \text{fvct}(x(\tau))$.

(ii) $G_r(x(t))$ contains no moderate-minded component.

(iii) Consider any open-minded SCC of $G_r(x(t))$, $S_k(x(t))$, and its leader SCC $S_\Theta(x(t))$, with adjacency matrices denoted by $\Theta_k$ and $\Theta_m$, respectively. Then,

(a) for any $i \in S_k(x(t))$, either $x_i(t) - \text{fvct}_r(x(t)) = 0$ or its per-step convergence factor converges to the spectral radius of $\Theta_m$ as time goes to infinity, and

(b) if the spectral radius of $\Theta_m$ is strictly less than that of $\Theta_m$, then there exists $t_1 \geq \tau$ such that for all $i \in S_k(x(t))$, $j \in S_m(x(t))$, and $t \geq t_1$,

$$x_j(t_1) < \text{fvct}_r(x(t_1)) \implies x_i(t) \leq \text{fvct}_r(x(t)),$$

$$x_j(t_1) > \text{fvct}_r(x(t_1)) \implies x_i(t) \geq \text{fvct}_r(x(t)).$$

In above theorem, parts (iii)a and (iii)b tell us, respectively, that the rates and directions of convergence of opinions in an open-minded SCC toward the final value at constant topology are governed by the rate and direction of convergence of its leader SCC. In our htHK model, the adjacency matrix of a large SCC has a large spectral radius. Theorem III.4 demonstrates that the per-step convergence factor of such SCC is also large. Owing to the inverse relation between the per-step convergence factor of an agent and its rate of convergence toward the final value, the rate of convergence of a large open-minded SCC toward final opinion vector is small. Therefore, Theorem III.4 tells us that in a society with fixed interconnection topology, individuals converge to a final decision as slow as the slowest group of agents to whom they directly or indirectly listen. An example for the importance of convergence direction is that individuals follow their leaders in converging to a final price from low to high or vice versa. However, the final prices might be different, since they collect separate sets of information from closed-minded agents. A proof to Theorem III.4 and some numerical examples to facilitate the understanding of the conditions and results of the theorem are provided in [14].

Remark 3 (Justification of the sufficient condition for monotonic convergence). We justify the conditions of Theorem III.3 employing Conjecture II.1 and Theorem III.4. Note that these conditions are sufficient but not necessary for monotonic convergence. Based on our conjecture, we assume that the topology of an htHK trajectory $x(t)$ remains unchanged after time $\tau$, thus condition (ii) of Theorem III.3 is satisfied. Regarding conditions (iii) and (iv) by statement (iii)a of Theorem III.4, there exist a time step $t_1 \geq \tau$, after which the per-step convergence factor of all agents belong to $[0,1]$. Therefore, the opinion vector converges toward its final value at constant topology monotonically in one step. Moreover, since the opinion vector is discrete, this monotonic convergence results in existence of a time step $t_2 \geq \tau$, after which condition (ii) of Theorem III.3 holds. Regarding condition (iv) statement (iii) of Theorem III.4 shows that there exists time step $t_3 \geq \tau$, after which for any open-minded $i$ and $j$ it is true that: if they both belong to one SCC, then $\Delta_i(x(t)) \Delta_j(x(t)) \geq 0$; and if they belong to two separate SCC’s with adjacency matrices $\Theta_1$ and $\Theta_2$, respectively, while $j$ is a successor of $i$, then when $\rho(\Theta_1) < \rho(\Theta_2)$, often it is true that $\Delta_i(x(t)) \Delta_j(x(t)) \geq 0$, and when $\rho(\Theta_1) > \rho(\Theta_2)$, $\Delta_j(x(t))$ converges to zero faster than $\Delta_j(x(t))$ and hence $\Delta_i(x(t)) \Delta_j(x(t)) \approx 0$. Regarding condition (v) part (a), if $i$ and $j$ have the same set of open-minded children at time $t$, then $k_i(x(t+1)) = k_j(x(t+1))$, see proof of Theorem III.3. Finally, we explain why the upper bound in condition (v) part (b) is less restrictive as time goes to infinity. Since, for such agent $i$, the distance to final values of all successors with smaller per-step convergence factors converge to zero, the
interval $[k_{\min}(x(t)), k_{\max}(x(t))]$ reduces to one value, that is $k_{\max}(x(t))$ to which $k_i(x(t))$ converges. Consequently, for large $t$, $k_{\max,j}(x(t)) = \max\{k_i(x(t)), k_j(x(t))\}$, $\alpha = k_j(x(t))$, and $\beta = k_i(x(t))$. Also, if $\Delta_j(x(t)) \geq \Delta_j(x(t))$, then $k_i(x(t)) \geq k_j(x(t))$, and hence

$$\min_{m,a,\beta} \left| 1 - \alpha^m \Delta_j(x(t)) \right| \geq 1 - \frac{\Delta_j(x(t))}{\Delta_j(x(t))}.$$ 

A system may monotonically converge under fixed topology while condition (v) of Theorem III.3 is not satisfied. However, Figure 3 illustrates the sufficiency of this condition.

### IV. CONCLUSION

In this paper, we studied the heterogeneous HK (htHK) model of opinion dynamics. We provided two novel sufficient conditions that guarantee convergence and constant interconnection topology for infinite time, while one condition also guarantees monotonicity of convergence. Furthermore, we demonstrated that in the evolution under fixed topology, individuals converge to a final decision as slow as the slowest group to whom they directly or indirectly listen. The main future challenge is to prove the eventual convergence of all htHK systems. One approach is to verify that any trajectory is ultimately confined to the basin of attraction of an equilibrium.

### APPENDIX

From here on, we often drop $y$ argument, and for any $y \in \mathbb{R}^n$, we denote $A(y)y$ by $y^±$ and $\text{fvec}(y)$ by $y^*$. 

**Proof of Lemma III.2** If there is no moderate-minded component in $G_r(y)$, then $y_0^s = y_0^t = \Theta(y)(y_0 - y_0^t)$, where $y_0^t$ is the opinion vector of the open-minded class whose adjacency matrix is $\Theta(y)$, see [14] Theorem 6.4]. Consider an open-minded agent $i$ whose children belong to the set $\{1, \ldots, m\}$, and denote the entries of the adjacency matrix $A(y)$ by $a_{ij}$, then

$$k_i(y^+) = a_{i1}(y_1^+ - y_1^1) + \cdots + a_{im}(y_m^+ - y_m^m) = a_{i1}(y_1 - y_1^1) + \cdots + a_{im}(y_m - y_m^m).$$

Under condition (iii) all $\Delta_j(y^+)$’s have the same sign, and hence all the terms in the right hand side are positive. Therefore, $k_i(y^+)$ is in the convex hull of $k_j(y^+)$’s.

**Proof of Theorem III.3** Here, we show that if $x(0) = 0$ satisfies all the theorem’s conditions, then $y^±$ also satisfies them, and similarly they hold for all subsequent times. Note that condition (iii) guarantees entrywise monotonic convergence, and condition (i) guarantees constant topology. Let us start by proving that $G_r(y) = G_r(y^+)$. On account of Proposition III.1 part (iii) and under condition (iii) there are no moderate-minded component in $G_r(y)$, thus, for any $i, j \in \{1, \ldots, n\}$, four cases are possible:

1. $i$ and $j$ are open-minded and weakly connected in $G_r(y)$.

   If $\Delta_i \geq \Delta_j > 0$, then without loss of generality we assume that $\Delta_i \geq \Delta_j > 0$, since otherwise we can multiply the opinion vector by $-1$. Hence, the monotonic convergence of the two opinions toward each other, or equivalently, $y_i^+ - y_j^+ \leq y_i - y_j$.

   $$\begin{align*}
   y_i^+ - y_j^+ &\leq y_i - y_j, \\
   \Delta_i &\geq \Delta_j > 0.
   \end{align*}$$

Fig. 3. Illustrates an htHK trajectory with $x_0 = [0.2 2.4 4.4 4.64 3.12]_T$ and $r = [0.01 0.01 0.01 0.01 1.9254 2.1 1.9]_T$ (left), and the non-monotonic evolution of the value $x_r(t) - x_0(t)$ if the proximity digraph remains fixed and equal to $G_r(x_0)$ (right), which is due to the large difference $k_0(x(t)) - k_7(x(t))$. The trajectory satisfies all conditions but (v) of Theorem III.3 at time steps $t = 0, \ldots, 5$. The proximity digraph $G_r(x_0)$ contains two open-minded SCC’s $\{x_0\}$ and $\{x_7, \ldots, x_{20}\}$, who are two open-minded WCC’s and weakly connected in $G_r(x_0)$. The per-step convergence factors of their agents, which is approximately equal to the spectral radius of the adjacency matrices of their SCC’s (0.3333 and 0.9804), do not satisfy the boundary condition (v). Therefore, the monotonic convergence of opinion vector, or equivalently equation (4), does not hold.

---

**Fig. 3.** Illustrates an htHK trajectory with $x_0 = [0.2 2.4 4.4 4.64 3.12]_T$ and $r = [0.01 0.01 0.01 0.01 1.9254 2.1 1.9]_T$ (left), and the non-monotonic evolution of the value $x_r(t) - x_0(t)$ if the proximity digraph remains fixed and equal to $G_r(x_0)$ (right), which is due to the large difference $k_0(x(t)) - k_7(x(t))$. The trajectory satisfies all conditions but (v) of Theorem III.3 at time steps $t = 0, \ldots, 5$. The proximity digraph $G_r(x_0)$ contains two open-minded SCC’s $\{x_0\}$ and $\{x_7, \ldots, x_{20}\}$, who are two open-minded WCC’s and weakly connected in $G_r(x_0)$. The per-step convergence factors of their agents, which is approximately equal to the spectral radius of the adjacency matrices of their SCC’s (0.3333 and 0.9804), do not satisfy the boundary condition (v). Therefore, the monotonic convergence of opinion vector, or equivalently equation (4), does not hold.
should be proved. Under condition [vi] it is true that \( |k_i - k_j| \leq (1 - \frac{\Delta_i}{\Delta_j}) \min \{1 - k_j, k_j\} \). On the other hand, for the sensing range of opinions of its agents; and its neighboring relation is preserved in both WCC’s of \( i \) from the opinion range of their opinions. Therefore, the sensing range of opinions of its agents, and its neighboring relation between \( i \) and \( j \) in the digraph \( G_r(y^*) \) is equal to that of \( G_r(y) \). Let \( r \) denote either \( r_i \) or \( r_j \). The sign of \( |y_i - y_j| - r \), \( |y_i - y_j + r| - r \), and \( |y_i - y_j| - r \) govern the neighboring relations between \( i \) and \( j \) in the digraphs \( G_r(y), G_r(y^*), \) and \( G_r(y^*) \), respectively. Using inequalities (3) and condition (ii)
\[
\begin{align*}
0 < y_i^* - y_j^* \leq y_i^* - y_j^* &\leq y_i - y_j & \text{if } y_i \geq y_j, \\
y_i^* - y_j^* \geq y_i^* - y_j^* \geq y_j - y_i &> 0 & \text{if } y_i \leq y_j,
\end{align*}
\]
subtracting \( r \) from above inequalities gives
\[
\begin{align*}
|y_i^* - y_j^*| - r &\leq |y_i^* - y_j^* - r| \leq |y_i - y_j - r| & \text{if } y_i \geq y_j, \\
|y_i^* - y_j^* - r| &\geq |y_j - y_i| - r & \text{if } y_i \leq y_j.
\end{align*}
\]
Hence, \( |y_i^* - y_j^* - r| \) is bounded between the two other values, which have the same sign by condition [ii]. Therefore, \( i \) and \( j \)'s neighboring relation is preserved in \( G_r(y^*) \).

b) If \( \Delta_i, \Delta_j \leq 0 \), then for instance assume that \( \Delta_i \geq 0 \geq \Delta_j \).

By condition [iii] it is easy to see that
\[
y_i - y_i^* \geq y_i^* - y_j^* \geq 0 \geq y_j^* - y_j \geq y_j - y_j^*.
\]
Using above inequalities and under condition [iii] inequalities (4) hold, which again proves that \( i \) and \( j \)'s neighboring relation is preserved in \( G_r(y^*) \).

2. \( i \) and \( j \) are open-minded and belong to two separate WCC’s of \( G_r(y) \), whose agent sets are \( V_1 \) and \( V_2 \). Since \( G_r(y) = G_r(y^*) \), by Proposition I.1 part [ii], the minimum and maximum opinions of a separate WCC in both \( G_r(y) \) and \( G_r(y^*) \) belong to closed-minded components. For any subgraph of \( G_r(y) \), let us define its opinion range to be a closed interval in \( \mathbb{R} \) between the minimum and maximum opinions of its agents; and its sensing range to be the union of closed intervals in the confidence bounds of its agents around their opinions. Therefore, the sensing range of \( V_1 \) is separated from the opinion range of \( V_2 \) in both \( G_r(y) \) and \( G_r(y^*) \). Due to monotonic convergence toward \( y^* \) in one step, the sensing range of \( V_1 \) in \( G_r(y^*) \) lies in the union of its sensing ranges in \( G_r(y) \) and \( G_r(y^*) \). The boundary closed-minded component of \( V_1 \) in \( G_r(y) \) keeps the sensing range of \( V_1 \) away from the opinion range of \( V_2 \) in \( G_r(y^*) \), see Figure 4(a). Thus, two separate WCC’s in \( G_r(y^*) \) remain separate in \( G_r(y^*) \).

3. \( i \) and \( j \) are both closed-minded in \( G_r(y) \), hence, \( y_i^* = y_i^* \) and \( y_j^* = y_j^* \). The equality \( y_i^* - y_j^* = y_i^* - y_j^* \) tells us that neighboring relation between \( i \) and \( j \) in \( G_r(y^*) \) is same as in \( G_r(y^*) \), and consequently in \( G_r(y^*) \).

4. \( i \) is open-minded and \( j \) is closed-minded in \( G_r(y) \). Since agents in one closed-minded component reach consensus in

\[ G_r(y^*) \], \( i \)'s neighboring relation with \( j \) in \( G_r(y^*) \) is the same as its relation with other agents in \( j \)'s component. Assume that \( y_i - y_j^* \leq r_i \), see Figure 4(b), then \( y_i - y_i^* \leq r_i \) for all \( k \) in \( j \)'s component. The average of the latter inequalities gives \( y_i - y_i^* \leq r_i \), and from \( G_r(y) = G_r(y^*) \) we have \( y_i^* - y_j^* \leq r_i \), where for closed-minded \( j \), \( y_j^* = y_j^* \). Therefore, \( y_j^* \), which under monotonic convergence is bounded between \( y_i \) and \( y_j^* \), also satisfies the inequality \( y_j^* - y_i^* \leq r_i \). Similarly, one can show that the neighboring relation is preserved in \( G_r(y^*) \) for the case when \( y_i - y_j \geq r_i \).

So far, we have proved that \( G_r(y) = G_r(y^*) \), hence condition [ii] holds for \( y^* \). Due to monotonic convergence in one step under opinion vector \( y \), opinion order and direction of convergence toward final value is preserved in \( y^* \), that is conditions [iii] and [iv] are true for \( y^* \). To prove the last two conditions for \( y^* \), we should find \( k_i(y^*) \)'s. Regarding part (a), if the two open-minded \( i \) and \( j \) have the same set of open-minded children, then equation (2) tells us that \( k_i(y^*) = k_j(y^*) \). Regarding part (b), clearly, both conditions of Lemma [III.2] hold for \( G_r(y) \), hence for any open-minded \( i \), \( k_i(y^*) \) lies in the convex hull of \( k_j(y) \)'s, where \( j \)'s are its open minded children. This fact tells us that: \( 0 \leq k_i(y^*) \leq 1 \), \( k_{\text{max}, i}(y^*) \leq k_{\text{max}, i}(y) \), and \( k_{\text{min}, i}(y^*) \geq k_{\text{min}, i}(y) \). Therefore, for any open-minded agents \( i \) and \( j \) with different sets of open-minded children,

\[
\begin{align*}
&k_{\text{max}, i}(y^*) - k_{\text{min}, i}(y^*) \leq \min_{m, \alpha_1, \beta_1} \left| 1 - \frac{\alpha_1 m \Delta_j(y)}{\beta_1 m \Delta_1(y)} \right| \times \min \{1 - k_{\text{max}, i}(y^*), k_{\text{min}, i}(y^*)\},
\end{align*}
\]
where \( \alpha_1 \in [k_{\text{min}, i}(y), k_{\text{max}, i}(y)] \), \( \beta_1 \in [k_{\text{min}, i}(y), k_{\text{max}, i}(y)] \), and \( m \in \mathbb{Z}_{\geq 0} \). Knowing that \( k_i(y) \in [k_{\text{min}, i}(y), k_{\text{max}, i}(y)] \),

\[
\begin{align*}
&\min_{m, \alpha_1, \beta_1} \left| 1 - \frac{\alpha_1 m \Delta_j(y)}{\beta_1 m \Delta_1(y)} \right| \leq \min_{m, \alpha_2, \beta_2} \left| 1 - \frac{\alpha_2 m \Delta_j(y)}{\beta_2 m \Delta_1(y)} \right|
\end{align*}
\]
the right hand side of the above inequality is equal to

\[
\begin{align*}
&\min_{m, \alpha_1, \beta_1} \left| 1 - \frac{\alpha_1 m \Delta_j(y)}{\beta_1 m \Delta_1(y)} \right| = \min_{m, \alpha_2, \beta_2} \left| 1 - \frac{\alpha_2 m \Delta_j(y^*)}{\beta_2 m \Delta_1(y^*)} \right|
\end{align*}
\]
where \( \alpha_2 \) and \( \beta_2 \), respectively, belong to smaller intervals of \( [k_{\text{min}, i}(y^*), k_{\text{max}, i}(y^*)] \) and \( [k_{\text{min}, i}(y^*), k_{\text{max}, i}(y^*)] \). Hence, part (b) holds for \( y^* \), which completes the proof.
