INTRODUCTION

Systemic arterial hypertension is a major risk factor for other cardiovascular diseases\(^1\) and is highly prevalent in both adults and elderly people.\(^2,3\) Data from the Brazilian National Health Survey revealed rates of 44.4%, 52.7% and 55.0% among Brazilian elderly people aged 60-64, 65-74 and ≥ 75 years, respectively,\(^4\) and the prevalence increased with age (71.7% of individuals aged ≥ 70 years had high blood pressure or reported taking antihypertensive medication).\(^3\)

Individuals with cardiovascular disease are at greater risk of complications from influenza.\(^5,6\) Besides the risk factors described in the literature (hypertension, obesity, physical inactivity, smoking, etc.), influenza contributes to cardiovascular morbidity and mortality.\(^6\) The American Heart Association and American College of Cardiology indicate the flu vaccine for individuals with atherosclerotic disease.\(^7\) The United Kingdom National Clinical Guideline Centre\(^8\) and the Brazilian Cardiology Society\(^9\) indicate the vaccine for individuals with heart failure.

Studies have shown that in individuals with cardiovascular disease, the flu vaccine reduces occurrences of cardiovascular events and mortality.\(^6,10\) Among individuals with hypertension, vaccination prior to the flu season has been significantly associated with reduction of the risk of death due to acute myocardial infarction, stroke and all causes.\(^10\)

In Brazil, the flu vaccine is offered through the public healthcare system to groups that are at risk (elderly people and individuals with chronic respiratory, heart, neurological, liver, kidney and metabolic diseases), as a strategy for prevention of the disease, its severe forms and complications.\(^11,12\) Higher rates of vaccination among individuals with hypertension have been observed since these campaigns began.\(^12,13\)

Since hypertension is a chronic disease that requires follow-up and treatment, most older adults in Brazil are dependent on the public healthcare system\(^14\) and primary care is the main source of antihypertensive medications.\(^15\) Thus, it can be hypothesized that this group is more attentive to information on vaccination campaigns and other offers from public healthcare services. However, after two decades of vaccine campaigns, approximately 20% of elderly people...
Reasons for non-vaccination against influenza among older adults with hypertension in Brazil: a cross-sectional study

OBJECTIVE

The aim of the present study was to estimate the prevalence of non-vaccination against influenza among older Brazilians with hypertension and determine the main reasons for non-adherence.

METHODS

A cross-sectional study was conducted using public domain data on elderly people (≥ 60 years) who participated in the 2013 National Health Survey, reported having hypertension (n = 5,524) and reported having not been vaccinated against influenza over the previous 12 months (n = 1,295). We estimated the absolute number and proportion of non-vaccinated elderly people with hypertension and the respective 95% confidence intervals, according to sociodemographic characteristics, and determined the reasons for non-vaccination.

All estimates were made using the Stata 14.0 software and took the sampling design into consideration. The National Health Survey had received approval from the National Ethics Committee of the Health Ministry (certificate number: 328.159; June 26, 2013).

RESULTS

The mean age of the elderly people with hypertension was 70.3 years (95% confidence interval, CI: 70.0-70.7), and 61.0% (95% CI: 58.8-63.2) were women. It was estimated that 3,026,080 elderly people with hypertension had not been vaccinated against influenza (22.6%; 95% CI: 20.9-24.5). No significant associations were found in relation to sex (P = 0.373), age group (P = 0.456) or schooling (P = 0.138). In comparison with the northern region of the country (27.9% not vaccinated), the prevalence of non-vaccinated elderly people was lower in the southern and southeastern regions (16.7% and 20.8%, respectively), even after adjusting for age. The prevalence of non-vaccination was higher among individuals without private health insurance (Table 1).

Table 1. Vaccination against influenza among older Brazilians with hypertension, according to sociodemographic characteristics. National Health Survey, 2013

| Variables                        | n  | Unvaccinated | Vaccinated |
|----------------------------------|----|--------------|------------|

CI = confidence interval (α = 0.05), considering the study design effect.
The main reasons for non-vaccination were fear of a reaction (28.6%; 95% CI: 24.9-32.6), rarely having the flu (22.0%; 95% CI: 18.9-25.4) and not believing in the protection of the vaccine (12.3%; 95% CI: 9.5-15.8) (Figure 1).

The prevalence of non-vaccination among elderly people with hypertension was lower than the rates found for elderly people in general and for those who reported not having hypertension (27.4% and 31.9%, respectively).

**DISCUSSION**

In the present study, the prevalence of vaccination against influenza among elderly people with hypertension was lower than what was expected for the general population of elderly people, given that the goal in 2013 was to vaccinate at least 80% of all individuals ≥ 60 years of age. Considering the greater contact of this group with healthcare services, the absolute number of unvaccinated individuals was high. Previous studies also found that there were no associations between the vaccination rate and sex, age group or schooling. Sato et al. found that the chance of having been vaccinated was greater among elderly people registered with the Family Health Program.

Regarding regional differences, the southern and southeastern regions of Brazil present socioeconomic differences in relation to the northeastern region. This may be reflected in access to healthcare services and, consequently, to information and counseling regarding the importance of vaccination. Moreover, the seasonality of influenza is more pronounced in the more southerly regions. In contrast, in northeastern Brazil, the peaks of the disease occur prior to the period when vaccination campaigns have been run, and this may have had an impact on the effectiveness of such campaigns as well as on the perceptions of elderly people regarding the protection offered by the vaccine, which thus will have had a negative influence on adherence.

The reasons for non-vaccination given by these elderly people with hypertension were similar to those found for the older population in general. Fear of side effects falsely attributed to the vaccine, not considering it important and having insufficient information regarding the benefits were the main reasons given. Counseling by healthcare professionals has been positively associated with vaccination and should be used as a strategy for improving knowledge among elderly people regarding both the disease and the vaccine.

**CONCLUSION**

The main reasons for non-vaccination (fear of a reaction, belief that influenza is a rare event, belief that the vaccine does not offer protection and fear of needles) accounted for more than 60% of the reasons given by these elderly people. These findings underscore the need for health professionals to explain to the population what the benefits of the vaccine are, regarding prevention of severe influenza (its protective effect and possible reactions) and secondary prevention of cardiovascular events. Increasing the prevalence of vaccination among elderly people with hypertension and other cardiovascular diseases is of fundamental importance within the realm of public health, as a strategy for reducing occurrences of complications and deaths associated with infection by the influenza virus.
