Graphical Abstract

Summary
Bioinformatic analysis as the first screening of β-galactosidase activity of multiple species and strains of LAB provides valuable information for selecting strains with this activity. Following inoculation in acid whey (AW) and commercial medium (de Man, Rogosa, and Sharpe; MRS), kinetic growth parameters were determined. To find strains with high β-galactosidase activity, different substrates were used (o-nitrophenyl-β-d-galactopyranoside and β-d-galactopyranoside). LAB showed higher β-galactosidase activity when cultured in AW compared with commercial MRS medium; thus, AW secondary metabolites likely complement the upregulation to promote enzyme production. Lactobacillus helveticus OSU-PECh-4A was identified as a strain with exceptional β-galactosidase activity. The bgal-620 gene was upregulated in OSU-PECh-4A cultured in AW. This strain can valorize AW and be used to further study β-galactosidase.

Highlights
• Lactic acid bacteria (LAB) have significant production of β-galactosidase despite low levels of cellular growth.
• Significantly lower lactose content of acid whey (AW) after LAB inoculation makes disposal more ecofriendly.
• L. helveticus strain OSU-PECh-4A displayed intense β-galactosidase activity when cultured in AW.
• To further understand the production of the β-galactosidase, quantitative PCR analysis should be used to evaluate real-time gene expression.
Screening and characterization of β-galactosidase activity in lactic acid bacteria for the valorization of acid whey

Petar Kolev, Diana Rocha-Mendoza, Silvette Ruiz-Ramírez, Joana Ortega-Anaya, Rafael Jiménez-Flores,* and Israel García-Cano*

Abstract: β-Galactosidase is an enzyme produced by some strains of lactic acid bacteria (LAB) commonly found in dairy products; however, industrial demand for these enzymes is still low. Acid whey (AW), a lactose-rich byproduct, has large output from cottage cheese and remains unexploited. The purpose of this study was to understand the production mechanism of β-galactosidase from LAB using AW as a culture medium. First, bioinformatics analysis was conducted on 15 species of LAB. Then, 24 strains were selected and inoculated in de Man, Rogosa, and Sharpe (MRS) broth and in AW medium to compare the bacterial kinetic growth and β-galactosidase production. Bacterial growth and total protein activity were measured using spectrophotometric techniques. β-Galactosidase activity was determined by 2 methods: following the hydrolysis of o-nitrophenyl-β-d-galactopyranoside and of 5-bromo-4-chloro-3-indoyl-β-d-galactopyranoside (X-gal) in tryptic soy agar plates. The relative expression of the β-galactosidase gene was performed using real-time quantitative PCR. Despite generally lower growth in AW, 18 strains showed higher β-galactosidase activity when grown in AW compared with MRS medium. The highest β-galactosidase activity in AW was in Lactobacillus helveticus strain OSU-PECh-4A, which showed almost 5 times higher activity than average. Analysis of 6 selected strains for expression of the bgal-620 gene found higher overexpression in AW than in MRS, regardless of specific β-galactosidase activity. Strains of LAB such as OSU-PECh-4A could valorize AW through the production of β-galactosidase (as an aid to lactose digestion) and production of prebiotic galactooligosaccharides.
β-galactosidase for the novel use of GOS production, or to reduce the biological oxygen demand of AW before disposal.

In this study, we used 137 strains of LAB from the Ohio State University Parker Endowed Chair (OSU-PECh) collection. The strains were isolated from a variety of dairy sources and were stored at −80°C in cryovials containing MRS (BD Difco) broth and glycerol (80%/20%; García-Canó et al., 2019). *Staphylococcus epidermidis* ATCC 1222 was used as a negative control and cultivated in brain heart infusion broth (BD Difco) and incubated at 37°C. The selection of specific LAB strains for screening was determined following bioinformatics analysis using the tools available from the National Center for Biotechnology Information (NCBI, https://www.ncbi.nlm.nih.gov/), which also allowed for the identification of genes (Pruitt et al., 2007), specifically the *bgal-620* gene encoding β-galactosidase.

The AW used in this work was obtained from Superior Dairy (Canton, OH) as a byproduct of cottage cheese production. To remove sediment and potential contaminants, the AW was centrifuged (Sorvall Legend XF, Thermo Scientific) at 13,664 × g at 4°C for 25 min, enriched with 0.5% final concentration of yeast extract (Sigma-Aldrich), and autoclaved before inoculation.

To screen the initial β-galactosidase activity of the bioinformatically selected strains, tryptic soy agar (Remel) plates were prepared, and 40 mL of 5-bromo-4-chloro-3-indolyl-β-d-galactopyranoside (X-gal 20 mg/mL, ThermoFisher Scientific) was added to each plate as a substrate and spread evenly (β-d-galactopyranoside test). The plates were dried for 30 min and then streaked with the MRS and AW cultures. A positive enzymatic result was indicated by the observation of a blue color surrounding the growth of the colonies, which is caused by cleavage of the β-d-galactopyranoside bond by β-galactosidase, releasing the blue color of the indole.

Ten microliters of each strain found to have β-galactosidase activity was inoculated in 3 mL of MRS broth and incubated at 37°C for 16 h. Following incubation, 50 mL of the broth was used to further inoculate one culture tube containing 3 mL of MRS broth and another containing 3 mL of AW. Then, 200 mL of the inoculated AW and MRS broth was transferred into separate wells within a sterile 96-well flat-bottomed plate (Corning Inc.). Growth curves were obtained by measuring the optical density at 600 nm (OD₆₀₀) in a microplate reader (Multiskan GO, ThermoFisher Scientific) with absorbance readings taken at 30-min intervals for 16 h at 37°C (Rocha-Mendoza et al., 2020).

Next, 1.5 mL of each AW and MRS culture was centrifuged at 16,000 × g at 4°C for 10 min (Centrifuge 5424, Eppendorf). The cell pellets were washed and resuspended in Tris-HCl buffer (50 mM, pH 7.6). The resuspended cells were diluted to an OD₆₀₀ of 5.00, placed on ice, and sonicated (Branson Ultrasonics Corp.) at 30 Hz for 7 min. The sonicated solution was centrifuged at 21,300 × g at 4°C for 10 min to eliminate cell debris and unbroken cells. The supernatant or protein extract was used for further assessment of enzymatic activity.

The total protein content was measured in the supernatant by transferring 1 mL of the solutions into a 1-mL high-precision quartz cuvette (Hellma Analytics), which blocks spectrophotometric interference, and the absorbance at 280 nm was measured. These readings were used to determine total protein content by using a standard curve prepared from known concentrations of BSA (Pierce/ThermoFisher Scientific).

The β-galactosidase activity in the protein extracts was determined using a modified procedure described by Bentahar et al. (2019). The method uses o-nitrophenyl-β-d-galactopyranoside (ONPG) to determine β-galactosidase activity. The ONPG molecule is colorless, but upon contact with β-galactosidase, it is cleaved to form galactose, which is colorless, and o-nitrophenyl, which is yellow. A 10 mg/mL solution of ONPG (Sigma-Aldrich) was prepared, and a 96-well plate was arranged with each well containing 100 mL of protein extract and 100 mL of ONPG solution. The blank was prepared using 100 mL of Tris-HCl (50 mM, pH = 7.8) buffer and 100 mL of ONPG solution. The samples were then incubated for 12 h at 37°C. Following incubation, 50 mL of 140 mM of Na₂CO₃ was added to each well of the plate to stop the reaction. Then, absorbance at 420 nm was measured. One unit (U) of β-galactosidase activity was defined as the change of 0.001 absorbance units (U) per min (U/min). The specific activity was correlated with the protein concentration (U/min × mg of protein).

In addition, LAB strains were cultured in AW and MRS broth. The cell pellet was recovered and washed as described previously. RNA and cDNA extraction followed the procedure described in Rocha-Mendoza et al. (2020) using the RNeasy Plus Mini Kit (Qiagen) according to the manufacturer’s instructions. A PCR was performed using the materials and instructions of the iScript RT kit (Bio-Rad) to synthesize cDNA from 1 mg of RNA. The extracted cDNA concentration was adjusted to 50 ng/mL and stored at −80°C.

The expression of *bgal-620* in each strain was measured using quantitative PCR methods described in Rocha-Mendoza et al. (2020). The primers were designed based on bioinformatics analysis using a recurring AA sequence that 93.8% of the LAB have present. We named this gene *bgal-620* and the primers used were as follows: 620F: 5′-GATCGCCACTCCGATTATGAA-3′ and 620R: 5′-AGCCATAATAATATCTCACCTG-3′. Real-time PCR was performed using the materials and instructions of the iScript RT kit (Bio-Rad) in a C1000 Touch Thermal Cycler (Bio-Rad). Expression of the *bgal-620* gene was normalized using the reference gene (16S rRNA). Analysis was performed using CFX Maestro Software 3.1 (Bio-Rad), under the ΔΔCq method, where Cq is the cycle threshold (CFX Maestro software user guide, version 1.1, 2017; Bio-Rad). Each experiment was performed in triplicate, and one-way ANOVA was run using JMP Pro 14 software (SAS Institute Inc.) to determine significant differences.

Table 1 shows the 3 key parameters obtained from the kinetic growth curves of the LAB: rate of bacterial growth (μMax); change in optical density at 600 nm (AOD₆₀₀), which indicates the total amount of bacterial growth; and lag time, which is the period during which bacteria adapt to their environment before beginning rapid cell division.

As expected, LAB cultured in MRS recorded significantly higher AOD₆₀₀ values, higher μMax values, and shorter lag times compared with LAB cultured in AW because of the rich composition of MRS broth, which includes peptone, beef extract, yeast extract, and glucose, providing sources of carbohydrates, nitrogen, vitamins, and minerals, making it an excellent medium for LAB.

Stark differences in AOD₆₀₀ for LAB cultured in MRS and AW were observed in *Lactobacillus acidophilus* OSU-PECh-1A, *Lactocaseibacillus casei* OSU-PECh-11A, and *Enterococcus munditii* OSU-PECh-39B. Another factor that can influence growth is the
pH of the medium. The initial pH of AW was 4.3 and that for MRS was 7.0. It is not surprising that the LAB used in this study have the ability to grow at acidic pH. Different LAB strains have been reported for their ability to grow at low pH (pH 4.3), indicating greater adaptation or sensitivity to pH (Rocha-Mendoza et al., 2020).

The longer lag times observed for LAB cultured in AW compared with MRS were likely due to the differences in carbohydrate content between the 2 media. The sole carbon source in MRS is glucose, which is readily fermentable by LAB, whereas the primary carbon source in AW is lactose, which necessitates the production of β-galactosidase for utilization. The lag times for L. helveticus OSU-PECh-4A cultured in AW and MRS had a greater than average difference, 10.32 and 6.59 h, respectively (P < 0.05). It is likely that this lag time is due to β-galactosidase production: the LAB with the highest specific β-galactosidase activity in both AW and MRS, but their activity in AW was significantly higher (P < 0.05), making the strains ideal for β-galactosidase production, as greater β-galactosidase activity values were obtained in AW (Figure 1A).

Enterococcus faecium OSU-PECh-75 was reported to lack β-galactosidase genes and it did have a positive result. Although not reported in Figure 1A, L. helveticus OSU-PECh-75 and Lactobacillus amylovorus OSU-PECh-32 do not have β-galactosidase activity (Becker and von Eiff, 2011). The results of the β-d-galactopyranoside test (Figure 1C) displayed the characteristics of positive and negative results. The ONPG test (Tse et al., 2012), indicating the potential risk of false positives from other bacteria. Examples of the characteristic blue color of bacterial colonies on β-d-galactopyranoside plates, differentiating bacteria that produce β-galactosidase from those that do not, are shown in Figure 1B.

The LAB with the highest specific β-galactosidase activity in AW were L. helveticus OSU-PECh-4A, and Enterococcus faecium OSU-PECh-27A, with specific activity of 3,331, and 1,110 mU/μmol, respectively. These strains displayed exceptional β-galactosidase activity in both AW and MRS, but their activity in AW was significantly higher (P < 0.05), making the strains ideal for β-galactosidase production, as greater β-galactosidase activity values were obtained in AW (Figure 1A).

The results of the β-d-galactopyranoside test (Figure 1C) conflicted with the results of the bioinformatics analysis, as all 24 strains selected were reported to contain β-galactosidase genes, but 5 strains did not show the ability to hydrolyze the X-gal substrate, which means that the gene was not expressed in the conditions tested. Conversely, Lactobacillus delbrueckii ssp. lactis OSU-PECh-75 was reported to lack β-galactosidase genes and it had a negative result. Although not reported in Figure 1A, L. helveticus OSU-PECh-75 and Lactobacillus amylovorus OSU-PECh-32 both displayed moderate β-galactosidase activity in AW. It was notable that these strains tested negative to the β-d-galactopyranoside test because a strain from each species tested positive: L. helveticus OSU-PECh-4A and Lactobacillus amylovorus OSU-PECh-16.

### Table 1. Key parameters of kinetic growth of selected strains of lactic acid bacteria

| Strain                        | Change in OD | Lag time (h) | Change in OD | Lag time (h) |
|-------------------------------|-------------|--------------|-------------|--------------|
| Lactobacillus acidophilus OSU-PECh-1A | 0.08        | 0.11         | 3.88        | 0.11         |
| Lactobacillus helveticus OSU-PECh-1B | 0.11        | 0.15         | 3.32        | 0.12         |
| Lactisaceibacillus casei OSU-PECh-2 | 0.14        | 0.34         | 35.22       | 0.09         |
| Lactobacillus helveticus OSU-PECh-4A | 0.05        | 0.55         | 10.32       | 0.06         |
| Lactobacillus acidophilus OSU-PECh-5 | 0.15        | 0.33         | 12.56       | 0.05         |
| Lactobacillus gasseri OSU-PECh-6B | 0.13        | 0.18         | 7.73        | 0.14         |
| Lactiplantbacillus pentosus OSU-PECh-6C | 0.1         | 0.15         | 3.88        | 0.08         |
| Lactisaceibacillus rhamnos OSU-PECh-8A | 0.12        | 0.23         | 4.59        | 0.14         |
| Lactisaceibacillus paracasei OSU-PECh-8B | 0.12        | 0.2         | 4.11        | 0.13         |
| Lactobacillus johnsonii OSU-PECh-9 | 0.11        | 0.21         | 5.35        | 0.13         |
| Lactobacillus gasseri OSU-PECh-10A | 0.12        | 0.21         | 4.11        | 0.15         |
| Lactisaceibacillus paracasei OSU-PECh-10B | 0.13        | 0.21         | 3.73        | 0.14         |
| Lactisaceibacillus casei OSU-PECh-11A | 0.12        | 0.26         | 5.83        | 0.13         |
| Lactobacillus crispatus OSU-PECh-11B | 0.15        | 0.5          | 8.84        | 0.15         |
| Pediococcus pentosaceus OSU-PECh-13 | 0.11        | 0.15         | 4.28        | 0.01         |
| Lactobacillus amylovorus OSU-PECh-16 | 0.14        | 0.29         | 4.25        | 0.12         |
| Enterococcus faecium OSU-PECh-27A | 0.06        | 0.11         | 9.47        | 0.03         |
| Lactobacillus amylovorus OSU-PECh-32 | 0.16        | 0.24         | 6.25        | 0.1          |
| Enterococcus munditii OSU-PECh-39B | 0.06        | 0.32         | 15.68       | 0.04         |

| Lactobacillus delbrueckii OSU-PECh-75 | 0.12        | 0.21         | 3.16        | 0.14         |

1AW = acid whey; MRS = de Man, Rogosa, and Sharpe; µMax = maximum growth rate; OD = optical density.
2OSU-PECh refers to strains in the Ohio State University Parker Endowed Chair collection.
Figure 1. (A) The specific β-galactosidase activity of proteins extracted from 24 strains of lactic acid bacteria (LAB) when cultured in acid whey (AW) and de Man, Rogosa, and Sharpe (MRS) broth, using o-nitrophenyl-β-d-galactopyranoside (ONPG) as a substrate. Error bars indicate the SD of 3 independent experiments. (B) Examples of positive and negative results of an β-d-galactopyranoside test. (C) Results of β-d-galactopyranoside test performed on selected strains of LAB. OSU-PECh refers to strains in the Ohio State University Parker Endowed Chair collection.
These results indicate either large variance in β-galactosidase production within LAB species or potential shortcomings of the β-d-galactopyranosidase method.

The bioinformatics analysis discovered a recurring gene in 93.8% of the LAB species selected in this study, between 625 and 644 AA in length, that we referred to as the bgal-620 gene. For the real-time quantitative PCR, 6 strains were selected, 2 with a negative result to the β-d-galactopyranoside test (L. helveticus OSU-PECh-1B and Lacticaseibacillus paracasei OSU-PECh-10B), 2 with moderate β-galactosidase activity (L. acidophilus OSU-PECh-1A and Lactiplantibacillus pentosus OSU-PECh-6C), and 2 with high β-galactosidase activity (L. helveticus OSU-PECh-4A and E. faecium OSU-PECh-27A). From Figure 2, it can be seen that all strains displayed higher gene expression when cultured in AW than in MRS, which corresponds to the greater production of β-galactosidase-encoding mRNA. For OSU-PECh-4A, OSU-PECh-6C, and OSU-PECh-27A, respectively, the expression was more than 3.3, 34, and 4 times greater when grown in AW medium than in MRS. Both OSU-PECh-1B and OSU-PECh-10B tested negative to the β-d-galactopyranoside test (Figure 1C); however, only OSU-PECh-10B displayed significant gene expression in AW. OSU-PECh-4A, which displayed the highest specific β-galactosidase activity using ONPG substrate, did not display the highest gene expression; instead, OSU-PECh-6C (moderate activity) showed the highest gene expression, closely followed by OSU-PECh-27A. It should be noted that the correlation between the content of a specific protein and mRNA specific to the protein is only about 40% (Vogel and Marcotte, 2012). Furthermore, in this experiment, the β-galactosidase content was measured indirectly through its specific activity, which results in a low correlation with the gene expression. Therefore, the strain with the highest specific β-galactosidase activity, OSU-PECh-4A, was not necessarily the strain with the highest gene expression. The one-way ANOVA tests determined that the differences in expression of bgal-620 in AW among the strains tested was significant (except for OSU-PECh-1B). These results imply that the environment that AW provides for LAB, where lactose is the sole carbon source, caused significant overexpression of the β-galactosidase gene, further showing that AW is an ideal medium for enzyme production.

Overall, 83.33% of LAB strains tested displayed higher specific β-galactosidase activity in AW than in MRS broth. Although this is to be expected, it was an unusually high response to production of this enzyme by some strains. The strains L. helveticus OSU-PECh-4A and E. faecium OSU-PECh-27A displayed exceptional specific β-galactosidase activity in AW. The β-d-galactopyranoside test confirmed the β-galactosidase activity of most strains selected by the bioinformatics analysis. Finally, we showed that all strains had higher expression of bgal-620 (encoding β-galactosidase) in AW compared with MRS, regardless of the results of the ONPG and β-d-galactopyranoside tests, indicating that there are factors that upregulate bgal-620.

In this work, we present the concept that AW from cottage cheese has some components that allowed certain LAB to produce high β-galactosidase activity compared with growth in MRS medium. It is very important to stress that L. helveticus OSU-PECh-4A characterized in this work grew normally in culture medium but in AW it produced 5 times more β-galactosidase activity. A strain with high β-galactosidase activity may be beneficial in improving the efficiency of lactose hydrolyzation in foods, to decrease the effects of lactose intolerance, and to stimulate the proliferation of beneficial bacteria in the human small intestine. In contrast, the combination of AW and LAB could be useful to reduce the environmental damage caused by AW disposal in wastewater and applied to other industrial waste streams (Maya-Apaza et al., 2021). It could also have an emerging use in producing beverages enriched in prebiotics such as GOS, taking advantage of the multifunctional enzymatic nature of β-d-galactosidase.
