TODORČEVIĆ' TRICHOTOMY AND A HIERARCHY IN THE CLASS OF TAME DYNAMICAL SYSTEMS

ELI GLASNER AND MICHAEL MEGRELISHVILI

Abstract. Todorčević trichotomy in the class of separable Rosenthal compacta induces a hierarchy in the class of tame (compact, metrizable) dynamical systems $(X, T)$ according to the topological properties of their enveloping semigroups $E(X)$. More precisely, we define the classes

$$\text{Tame}_2 \subset \text{Tame}_1 \subset \text{Tame},$$

where $\text{Tame}_1$ is the proper subclass of tame systems with first countable $E(X)$, and $\text{Tame}_2$ is its proper subclass consisting of systems with hereditarily separable $E(X)$. We study some general properties of these classes and exhibit many examples to illustrate these properties.

Introduction

In this work we continue our study of the following theme:

\textit{Date:} 2021, July 7.

\textit{2010 Mathematics Subject Classification.} Primary 37Bxx; Secondary 54H15, 54H05, 54F05.

\textit{Key words and phrases.} almost automorphic system, circular order, enveloping semigroup, linear order, Rosenthal compact, Sturmian system, tame dynamical system.

This research was supported by a grant of the Israel Science Foundation (ISF 1194/19).
Problem 0.1. Let $T$ be a topological group and $(X,T)$ a compact dynamical system. Let $E := E(X,T)$ be the enveloping semigroup of $(X,T)$. How is the topology of the compact space $E$ related to the dynamical properties of the system $(X,T)$?

For the background and history of research in this direction see, for example, the survey papers [31], [40]. It is a well known phenomenon that enveloping semigroups of compact metrizable dynamical systems often are nonmetrizable huge compacts. Recall that by [45], $E(X)$ is metrizable if and only if $(X,T)$ is hereditarily nonsensitive (HNS); see below the short explanation in Section 0.1. This is a quite restricted class of systems, although it contains the weakly almost periodic (WAP) systems.

A much larger class is that of dynamical systems $(X,T)$ for which $E(X)$ is a Rosenthal compactum. It coincides with the class of tame metrizable dynamical systems. This fact is a consequence of the dynamical analog of the Bourgain–Fremlin–Talagrand dichotomy theorem [37] (see Theorem 0.5 below). Thus tame systems play a principal role when we address the above problem. Many remarkable naturally defined systems coming from geometry, analysis and symbolic dynamics are tame but not HNS.

In the present paper we introduce two subclasses of tame metric dynamical systems.

Definition 0.2. Let $(X,T)$ be a compact metrizable dynamical system and $E(X,T)$ be its (necessarily separable) enveloping semigroup. We say that this system is:

1. tame$_1$ if $E(X,T)$ is first countable;
2. tame$_2$ if $E(X,T)$ is hereditarily separable.

The corresponding classes will be denoted by Tame$_1$ and Tame$_2$ respectively. As is shown in Proposition 0.6 below, we have

$\text{Tame}_2 \subset \text{Tame}_1 \subset \text{Tame}$.

This hierarchy arises naturally from deep results of Todorčević and Argyros–Dodos–Kanellopoulos about separable Rosenthal compacta.

Theorem 0.3. (Todorčević’ Trichotomy [61], [4, Section 4.3.7]) Let $K$ be a non-metrizable separable Rosenthal compactum. Then $K$ satisfies exactly one of the following alternatives:

1. $K$ is not first countable (it then contains a copy of $A(c)$, the Alexandroff compactification of a discrete space of size continuum).
2. $K$ is first countable but $K$ is not hereditarily separable (it then contains either a copy of $D([0,1]^{3\aleph_0})$, the Alexandroff duplicate of the Cantor set, or $\widehat{D}(S([0,1]^{3\aleph_0}))$, the extended duplicate of the split Cantor set).
3. $K$ is hereditarily separable and non-metrizable (it then contains a copy of the split interval).

By results of R. Pol [57, Section 4, Theorem 3.3], every hereditarily separable Rosenthal compact space is first countable (see Debs [15]). (A topological space $K$ is perfectly normal if it is normal and every closed subset of $K$ is a $G_\delta$ set.)

Theorem 0.4. For a separable Rosenthal compactum $K$ the following conditions are equivalent:

1. $K$ is perfectly normal.
(2) $K$ is hereditarily separable.
(3) $K$ contains no discrete subspace of cardinality continuum.

We also observe that $A(c)$ is a continuous image of $D(\{0, 1\}^\mathbb{N})$ (we refer to [61, 15] for the definition and discussion of these spaces). Thus a first countable Rosenthal compactum can admit a quotient which is not first countable. We will have a similar situation among our tame classes; namely a tame system can admit a factor which is not tame (Examples 5.7, 5.8 and Lemma 7.6). Also, as we will see (Proposition 4.1), the product of two tame systems need not be tame. Note that the class Tame is closed under subsystems and factors. The class Tame is closed under countable products but not under subsystems (see Examples 5.9 below).

0.1. Preliminaries. Recall that for any topological group $T$ and any dynamical $T$-system $X$, defined by a continuous homomorphism $j: T \to \text{Homeo}(X)$ into the group of homeomorphisms of the compact space $X$, the corresponding enveloping semigroup $E(X, T)$ (or just $E(X)$, $E$ when $T$ and $X$ are understood) was defined by Robert Ellis as the pointwise closure of the subgroup $j(T)$ of $\text{Homeo}(X)$ in the product space $X^X$. One may easily modify this definition for semigroup actions.

$E(X, T)$ is a compact right topological semigroup whose algebraic and topological structure often reflects dynamical properties of $(X, T)$.

Let $\pi: X \to Y$ be a factor map of $T$-systems (i.e., $\pi(tx) = t\pi(x)$ for all $t \in T$ and $x \in X$). Then there exists a (unique) continuous surjective semigroup homomorphism $\pi_*: E(X) \to E(Y)$ such that $\pi \circ p = \pi_*(p) \circ \pi$ for every $p \in E(X)$ and such that $\pi_*(j_X(t)) = j_Y(t)$ for every $t \in T$.

For more information about dynamical systems and their enveloping semigroups we refer to [31] and [40]. Of special interest for us will be the successively larger classes of almost periodic (AP), weakly almost periodic (WAP), hereditarily nonsensitive (HNS), and tame dynamical systems. We include here some information about the class of tame systems.

**Tame dynamical systems.** A real valued bounded continuous function $f \in C(X)$ is said to be tame if the family $fT := \{f \circ t : t \in T\}$ of real valued functions has no independent infinite sequence (in the sense of H. Rosenthal, [58]); we denote by Tame($X$) the collection of these functions.

By [38] $f$ is tame iff for every $p \in E(X, T)$ the function $f \circ p: X \to \mathbb{R}$ has the point of continuity property (PCP in short). The system $(X, T)$ is tame if Tame($X$) = $C(X)$. A metric dynamical system $(X, T)$ is tame iff every element $p$ of the enveloping semigroup $E = E(X, T)$ is a limit of a sequence of elements from $T$, [37, 45], iff $p$ is of Baire class 1. Another equivalent condition is that $\text{card} E(X)$ is $\leq 2^{\aleph_0}$ (Theorem 0.5).

Tame dynamical systems were introduced by A. Köhler [50] under the name **regular systems.** The term “tame” was proposed later in [32].

Tame dynamical systems form a class of low complexity dynamical systems where several remarkable dynamical and topological properties meet. This class is quite large and is closed under subsystems, products and factors. By the dynamical analog of the Bourgain–Fremlin–Talagrand theorem, a compact metrizable dynamical system is tame if and only if its (always, compact and separable) enveloping semigroup $E(X, T)$ is a Rosenthal compact space. More precisely we have:
Theorem 0.5. (A dynamical version of BFT dichotomy) Let \((X, T)\) be a compact metric dynamical system and let \(E\) be its enveloping semigroup. Either

1. \(E\) is a separable Rosenthal compact space (hence \(E\) is a Fréchet-Urysohn space and \(\text{card} E \leq 2^\aleph_0\)); or
2. \(E\) contains a homeomorphic copy of \(\beta\mathbb{N}\) (hence \(\text{card} E = 2^{2^{\aleph_0}}\)).

The first possibility holds if and only if \((X, T)\) is a tame system.

The metrizable tame systems are exactly those systems which admit a representation on a separable Rosenthal Banach space \([38]\) (a Banach space is called Rosenthal if it does not contain an isomorphic copy of \(l_1\)). An important subclass of the class of Rosenthal Banach spaces is the class of Asplund Banach spaces. (A Banach space \(V\) is Asplund iff its dual has the Radon-Nikodým property iff the dual of every separable linear subspace of \(V\) is separable. Reflexive spaces and spaces of the type \(c_0(\Gamma)\) are Asplund, and every Asplund space is Rosenthal.) We denote by RN the class of Radon–Nikodým dynamical systems (see \([37]\)). A (metrizable) dynamical system is said to be RN if it is representable on a (resp., separable) Asplund Banach space.

Any RN system \(X\) is hereditarily non-sensitive (HNS) and any HNS system is tame. A metric system is RN iff it is HNS. It was shown in \([45]\) that a metric system \((X, T)\) is RN iff its enveloping semigroup \(E(X, T)\) is metrizable.

Any continuous topological group action on a dendrite is tame, \([43]\). Circularly (in particular, linearly) ordered dynamical \(T\)-systems are RN, hence tame, \([41]\).

Yet another characterization of tameness, of combinatorial nature via the notion of independence tuples, is due to Kerr and Li \([52]\). For more information and references about tame systems see \([42, 40]\).

For the definitions of WAP and AP see Remark \([1.3]\). For the definition and basic properties of HNS we refer to \([37, 45]\). The following inclusions hold in general

\[ \text{AP} \subset \text{WAP} \subset \text{HNS} \subset \text{Tame}. \]

Proposition 0.6. For metrizable systems we have the following inclusions

\[ \text{RN} = \text{HNS} \subset \text{Tame}_2 \subset \text{Tame}_1 \subset \text{Tame}. \]

Proof. The dynamical BFT dichotomy (Theorem 0.5) implies that \(\text{tame}_1\) and \(\text{tame}_2\) systems are tame (hence, \(E(X, T)\) is a Rosenthal compactum in both cases). In fact, a \(\text{tame}_1\) system is tame because a first countable space is Fréchet-Urysohn. Finally, the above mentioned result of R. Pol (Theorem 0.4) implies that \(\text{Tame}_2 \subset \text{Tame}_1\). □

When a metric system is \(\text{tame}_2\) we have the following detailed information. This is a version of a theorem from \([37, Proposition 15.1]\), which in turn is based on results of S. Todorčević, \([61, Theorem 3]\):

Theorem 0.7. Let \(X\) be a metric tame, point transitive \(T\)-system, where \(T\) is an arbitrary topological group.

Then

1. Either \(E(X, T)\) contains an uncountable discrete subspace (i.e. it is not \(\text{tame}_2\)) or,
There exists a metric tame system $(Z,T)$ and a factor map $Z \to X$ such that $E(X,T) = E(Z,T)$ and such that, with $\pi: E(X,T) \to Z$, the evaluation map $p \mapsto p_{z_0}$, where $z_0 \in Z$ is any transitive point, we have $|\pi^{-1}(z)| \leq 2$, $\forall z \in Z$.

**Proof.** Suppose that $E(X,T)$ does not contain an uncountable discrete subspace. Then there exists, by [37, Theorem 15.1] a factor map $\phi: E(X,T) \to Y$ for some metric system $(Y,T)$ such that $|\phi^{-1}(y)| \leq 2$ for every $y \in Y$. Let $x_0 \in X$ and $y_0 \in Y$ be transitive points and set $z_0 = (x_0, y_0)$ and $Z = T(x_0, y_0)$. Then the system $(Z,T)$ is metric and tame with $E(X,T) \to Z \to X$, such that $E(Z,T) = E(X,T)$, and the evaluation map $\pi: p \mapsto p(x_0, y_0)$ from $E(X,T) \to Z$ to is at most 2 to 1. □

**Remark 0.8.** Dynamical systems with the group $Z$ of integers as the acting group are sometimes called cascades. Often when dealing with cascades we change our notation and denote our system as $(X,T)$, where here the letter $T$ denotes the homeomorphism of $X$ which corresponds to $1 \in Z$.

**Remark 0.9.**

1. Note that every linearly ordered compact separable space $X$ is homeomorphic to a special linearly ordered space $K_A$ which can be obtained using a splitting points construction. More precisely, by a result of Ostaszewski (see [55] and its reformulation [54, Result 1.1]) for $X$ there exist: a closed subset $K \subset [0,1]$ and a subset $A \subset K$ such that $K_A = (K \times \{0\} \cup (A \times \{1\}))$ is endowed with the corresponding lexicographic order inherited from $K \times \{0,1\}$. Every splitting point is singular (see definition in Section 8). Hence, Lemma 8.6 implies that $K_A$ is metrizable if and only $A$ is countable.

2. The splitting point construction can be generalized in several directions. Among others for circularly ordered compact spaces. In [41, 44] we use such circularly ordered versions of Ostaszewski type spaces $K_A$ (which, as in [41], we denote by Split($K;A$)) the space which we get after splitting points of $A \subset K$ in the circularly ordered space $K$. We use such examples also in the present paper. In particular, in Proposition 4.1 we have the space $T_A$, with $A := \{n\alpha : n \in \mathbb{Z}\}$ and the double circle $T_T$ (see also Corollary 8.2).

Some highlights of the present work.

1. In Theorem 2.3 we give a sufficient condition for the tame$_1$ property for almost one-to-one extensions $X \to Y$ of a tame$_1$ system $Y$. This implies, in particular, that $X$ is tame$_1$ for the following symbolic systems: (a) Tribonacci 3-letter substitution system; (b) Arnoux-Rouzy substitutions; (c) Brun substitution; (d) Jacobi-Perron substitution.

2. By Theorem 2.5 the Floyd minimal set is tame$_1$.

3. By Corollary 6.6 The action of a hyperbolic group $\Gamma$ on its Gromov boundary $\partial \Gamma$ is tame but not tame$_1$.

4. Proposition 4.1 shows that there exists a tame$_1$ almost automorphic $\mathbb{Z}$-system which is not tame$_2$.

5. By Theorem 7.1 every linear action $GL(n, \mathbb{R}) \times \mathbb{R}^n \to \mathbb{R}^n$ is tame but, for $n \geq 2$ it is not tame$_1$. 
(6) As we have shown in [41] circularly ordered $T$-dynamical systems are tame. This implies that many Sturmian like symbolic dynamical systems are tame. Now we can say more: Here we show that Sturmian like systems are tame, Corollary [8.3]. And every linearly ordered metric system is tame, Theorem [8.8].

(7) By Proposition [8.10] the circularly ordered system $(\mathbb{T},H_+)$ is tame but not tame, where $H_+\mathbb{T}$ is the Polish topological group of all c-order preserving homeomorphisms of the circle $\mathbb{T}$. Note also that the “circular analog of Helly’s space” $M_+(\mathbb{T},\mathbb{T})$ (which is a separable Rosenthal compactum) is not first countable (see Remark [8.11]).

We thank Gabriel Debs, Jan van Mill, and Roman Pol for helpful (e-mail) discussions. We thank the anonymous referee for his many helpful suggestions.

1. $G_\delta$-points in enveloping semigroups $E(X,T)$

We recall the following well known result.

**Lemma 1.1.** [23, 3.1.F] Let $X$ be a compact space. A point $x_0 \in X$ is a $G_\delta$ point if and only if there is a countable basis for the topology at $x_0$.

The following useful result is a generalization of [11, Proposition 2].

**Proposition 1.2.** Let $X$ be a set, $(Y,d)$ a metric space, and $E \subset Y^X$ a compact subspace in the pointwise topology. The following conditions are equivalent:

1. a point $p \in E$ admits a countable local basis in $E$;
2. there is a countable set $C \subset X$ which determines $p$ in $E$, meaning that for any given $q \in E$, the condition $q(c) = p(c)$ for all $c \in C$ implies that $q(x) = p(x)$ for every $x \in X$.

**Proof.** We note that the following collection of subsets forms a basis for the topology at a point $p \in E$:

\[ V(x_1,x_2,\ldots,x_n;\epsilon) = \{ q \in E : d(px_i,qx_i) < \epsilon ; 1 \leq i \leq n \}, \]

with $\{ x_1,x_2,\ldots,x_n \}$ a finite subset of $X$ and $\epsilon > 0$.

Assuming that $p$ admits a countable basis for its topology, there is then also a basis for this topology whose elements of the form (1.1), and the union of all those finite sets that appear in this representation clearly forms a countable set $C \subset X$ which determines $p$.

Conversely, when $p$ is determined by its values on a countable subset $C \subset X$, it is clearly a $G_\delta$ point of $E$ and thus, by Lemma [1.1] it admits a countable base for its topology.

**Remark 1.3.**

1. Recall that a $T$-system $X$ is WAP (weakly almost periodic) if and only if every $p \in E(X,T)$, as a function $p: X \to X$, is continuous [22]. Clearly then for a metric WAP system each countable dense subset $D \subset X$ determines every $p \in E(X,T)$. 

(2) A system \(Y\) is AP (= equicontinuous) if and only every \(p \in E(X)\) is a homeomorphism of \(X\). In this case \(E(X, T)\) is a compact topological group. If, in addition, the action of \(T\) on \(X\) is point transitive (i.e., has a dense orbit) then \(X\) is a coset space \(E(X, T)/H\) for some closed subgroup \(H\) of \(E(X, T)\). When \(T\) is abelian, \(H\) is trivial and \(X\) is identified with the topological compact group \(E(X, T)\). In this case each element \(p \in E(X, T)\) is completely determined by its value at any single point \(x\) of \(X\).

**Remark 1.4.** Note that if one can choose a countable subset \(C \subset X\), as in Proposition 1.2, which is independent of \(p\), then the map \(p \mapsto (px)_{x \in C} \in X^C\), is a topological embedding, and it follows that \(E(X)\) is metrizable. Thus, in view of [45], the existence of such a set is a sufficient condition for a metric \((X, T)\) to be a HNS system. (It is also necessary, because cylindrical sets in \(E(X) \subset X^X\) form a basis for the topology, so that when \(E(X)\) is a metric space, this basis admits a countable subfamily which is also a basis.)

By a theorem of Bourgain [11], in every Rosenthal compactum \(K\) the set of \(G_\delta\)-points is dense. As remarked by Debs, since any non empty \(G_\delta\) subset of \(K\) contains a non empty compact \(G_\delta\) subset, it follows from Bourgain’s result that the set of all \(G_\delta\)-points of a Rosenthal compactum is actually non meager. [In fact, let \(D \subset X\) be the collection of \(G_\delta\)-points in \(X\). If \(D\) is meager it is contained in a union \(\bigcup_{n \in \mathbb{N}} K_n\) where each \(K_n\) is closed with empty interior. Now

\[
X \setminus \bigcup_{n \in \mathbb{N}} K_n = \bigcap_{n \in \mathbb{N}} K_n^c
\]

is a \(G_\delta\) subset of \(X\), hence contains a compact \(G_\delta\) set which, in turn, contains a \(G_\delta\) point by the proof of Bourgain’s theorem].

Debs remarks in [15] however that the question whether the set of all \(G_\delta\)-points of a Rosenthal compactum \(K\) is comeager in \(K\) is still open.

**Question 1.5.** For a metric tame system \((X, T)\) is the set of all \(G_\delta\)-points of \(E(X, T)\) comeager ?

In order to formulate a related question we need some notations.

Let \(I\) be the unit interval, \(\Omega = I^I, \Sigma = \{0, 1\}^I\). Let

\[
\Sigma_c = \{\sigma \in \Sigma : |\text{supp}(\sigma)| \leq \aleph_0\}.
\]

For \(p \in \Omega\) and \(C \subset I\) let

\[
\Omega_C(p) = \{q \in \Omega : q \upharpoonright C = p \upharpoonright C\}.
\]

Now, suppose \(A \subset \Omega\) is a closed subset. Consider the sets:

\[
\mathcal{G} = \{(p, C) : \Omega_C(p) \cap A = \{p\}\} \subset A \times \Sigma_c,
\]

\[
G = \{p \in A : \exists C \in \Sigma_c, \Omega_C(p) \cap A = \{p\}\} = \pi_1(\mathcal{G}),
\]

where elements of \(\Sigma_c\) are identified with their supports and \(\pi_1\) is the projection on \(\Omega\). So \(G\) is a kind of an ‘analytic’ set.

**Question:** Is \(G\) a Baire set; i.e. of the form \(U \Delta M\) for \(U \subset \Omega\) open and \(M \subset \Omega\) meager ?
In a private communication Jan van Mill have shown that in general the answer

to this question may be negative. However, in our case we have further information

concerning the set $A$ that might be relevant. The compact set $A \subset \Omega$ is a separable

Rosenthal compactum (so in particular a Fréchet-Urysohn space). Thus by Bourgain’s

theorem it has a dense (and non-meager) subset of $G_\delta$ points.

Note that if we know that the set of $G_\delta$ points in a separable compactum $K$ is a

Baire set, then it is comeager.

Question 1.6. Among the class of separable Rosenthal compacta, which members are

homeomorphic to $E(X,T)$ (or Adh $(X,T)$, see Section [5] for some system $(X,T)$

(with $(X,T)$ metric, minimal, $T$ abelian, $T = \mathbb{Z}$ etc.) ?

2. When is an almost automorphic system tame ?

Almost automorphic dynamical system were first studied by Veech in [62]. Since

then they play a central role in various aspects of the theory of dynamical systems.

Definition 2.1. Let $\pi : (X,T) \rightarrow (Y,T)$ be a factor map of metric minimal dynamical

systems.

(1) $\pi$ is said to be an \textit{almost one-to-one extension} if the set

$$X_0 := \{x \in X : \pi^{-1}(\pi(x)) = \{x\}\}$$

is a dense $G_\delta$ subset of $X$. When $\pi$ is an almost one-to-one extension we let

$$Y_0 = \pi(X_0) = \{y \in Y : |\pi^{-1}(y)| = 1\}.$$ 

When the set $Y \setminus Y_0$ is countable we say that $\pi$ is of \textit{type c}, and we say that $\pi$ is of \textit{type cc} when $X \setminus X_0$ is countable. \footnote{In [12] we used the term 'strongly almost one-to-one' for the type cc property.}

(2) $(X,T)$ is \textit{almost automorphic} if there exists an almost one-to-one extension

$\pi : (X,T) \rightarrow (Y,T)$ with an equicontinuous system $(Y,T)$; we denote by AA

the class of almost automorphic systems.

(3) We say that an almost automorphic system $(X,T)$ is:

(a) of \textit{type AA}_c when the corresponding set $Y \setminus Y_0$ is countable;

(b) of \textit{type AA}_cc when $X \setminus X_0$ is countable.

Thus, we have

$$\text{AA}_cc \subset \text{AA}_c \subset \text{AA}.$$ 

As was shown in [33, Corollary 5.4.(2)], a minimal metric tame system $(X,T)$ which

admits an invariant measure is almost automorphic and moreover, the invariant mea-

sure is unique and the almost one-to-one map $\pi : X \rightarrow Y$, from $X$ onto its maximal

equicontinuous factor, is an \textit{isomorphic extension}, i.e. $\pi$ is a measure theoretical iso-

morphism when $Y$ is equipped with its Haar measure. It was shown recently in [26,

Corollary 3.7] that a tame AA system is necessarily regular (i.e. the unique invariant

measure is supported on the set $X_0$ of singleton fibers). Of course there are many

eamples of AA systems which are not tame. For example there are almost auto-
morphic systems having more than one invariant measure, or having positive entropy,
and in [28, Theorem 3.11, Corollary 3.13] there are examples of regular AA systems which are not tame.

**Proposition 2.2.** Let \((X, T)\) be an AA\(_{cc}\) system with \(T\) abelian. Then \(E(X, T)\) is first countable (hence \((X, T)\) is tame\(_1\)).

**Proof.** Note first that for a minimal equicontinuous system \((Y, T)\) with \(T\) abelian, an element \(p \in E(Y, T)\) is completely determined by its value at any single point \(y\) of \(Y\) (Remark 1.3 (2)). Now let \(\pi: X \to Y\) be the largest equicontinuous factor of \((X, T)\) and let \(X_0 = \{x \in X : \pi^{-1}(\pi(x)) = \{x\}\}\). By assumption the set \(C = X \setminus X_0\) is countable. Given \(p \in E(X, T)\), consider the set \(C_p = \{x \in X : px \in C\}\). This is at most countable, and taking into account the above remark, if we know the restriction of \(p \in E(X, T)\) to \(C_p\), we know \(p\). Now apply Proposition 1.2. \(\square\)

A more general statement is as follows:

**Theorem 2.3.** Let \(\pi: (X, T) \to (Y, T)\) be an almost one-to-one extension of type cc, and let \(\pi_*: E(X) \to E(Y)\) be the induced surjective homomorphism. Suppose \(p \in E(X)\) satisfies:

(a) \(E(Y)\) is first countable at \(\pi_*(p)\);
(b) \(\pi_*(p)^{-1}(y)\) is at most countable for every \(y \in Y\).

Then \(E(X, T)\) is first countable at \(p\). Furthermore, if the conditions above (a), (b) are true for every \(p \in E(X)\) then \(X\) is tame\(_1\).

**Proof.** In order to prove that \(E(X)\) is first countable at \(p\), according to Proposition 1.2 we have to show that there exists a countable subset \(C(p)\) which “determines” \(p\). That is, \(p'(x) = p(x)\) for every \(x \in C(p)\) and \(p' \in E(X, T)\) implies \(p = p'\).

For our \(p \in E(X)\) choose first a countable subset \(C(\pi_*(p))\) of \(Y\) which “determines” \(\pi_*(p)\) in \(E(Y)\) (such a set exists by Proposition 1.2 because \(E(Y)\) is first countable at \(\pi_*(p)\)). Fix a countable subset \(A\) of \(X\) such that \(\pi(A) = C(\pi_*(p))\).

By Definition 2.1 the set \(X \setminus X_0\) is countable, where \(X_0 := \{x \in X : \pi^{-1}(\pi(x)) = \{x\}\}\). Set \(Y_0 := \pi(X_0)\). Define now

\[
B := \pi^{-1}(\pi_*(p)^{-1}(Y \setminus Y_0)).
\]

Since \(Y \setminus Y_0\) is countable then \(\pi_*(p)^{-1}(Y \setminus Y_0)\) is countable (use (b)). Since \(\pi\) is of type cc (Definition 2.1 (1)) it follows that the preimage \(\pi^{-1}(y)\) is countable for every \(y \in Y\). Hence, \(B\) is also continuous. Now we claim that the countable set

\[
C(p) := A \cup B
\]
determines \(p\). It is enough to verify the following

**Claim.** Let \(p', p \in E(X)\).

(i) If \(p'(a) = p(a)\) \(\forall a \in A\). Then \(\pi_*(p') = \pi_*(p)\).
(ii) Assume that \(\pi_*(p') = \pi_*(p)\). If \(p'(x) = p(x)\) \(\forall x \in B\) then \(p' = p\).

**Proof of (i):** note that \(\pi p'(a) = \pi p(a)\) \(\forall a \in A\). Therefore, \(\pi_*(p')(\pi(a)) = \pi_*(p)(\pi(a))\) \(\forall a \in A\). So, \(\pi_*(p')(y) = \pi_*(p)(y)\) \(\forall y \in C(\pi_*(p))\). This means that \(\pi_*(p') = \pi_*(p)\).

**Proof of (ii):** it is enough to show that for every \(x \notin B\) we have \(p'(x) = p(x)\).
So let $x \notin B$. Then $\pi_*(p)(\pi(x)) \in Y_0$. By definition of $X_0$ there exists unique element $z \in X$ such that $\pi(z) = \pi_*(p)(\pi(x))$. Since $\pi p(x) = \pi_*(p)\pi(x)$ we have $p(x) = z$. Moreover, since $\pi_*(p') = \pi_*(p)$ we have also $p'(x) = z$. So, $p' = p$. □

**Remark 2.4.**

1. The dynamical system $(X, T)$ from Theorem 2.3, in particular, is tame (being tame$_1$, see Proposition 0.6). This strengthens [42, Theorem 6.16]. Similarly, Proposition 2.2 in turn, strengthens a result of Huang [48].

2. Proposition 2.2 together with results of Jolivet [49, Theorem 3.1.1], imply that $E(X)$ is first countable (i.e., $X$ is tame$_1$) for the following symbolic systems:
   (a) Tribonacci 3-letter substitution system;
   (b) Arnoux-Rouzy substitutions;
   (c) Brun substitution;
   (d) Jacobi-Perron substitution.

A similar argument will show that the Floyd minimal set [24], which is AA$_c$ but not AA$_{cc}$, is tame$_1$. For more details on this dynamical system see [7] and [47].

**Theorem 2.5.** The Floyd minimal set, which is AA$_c$ but not AA$_{cc}$, is tame$_1$.

**Proof.** Let $(X, T)$ be the Floyd minimal system, with $\pi : X \to Y$ the almost one-to-one factor map onto its largest equicontinuous factor $Y$, which is the 3-adic adding machine. In Figure 1 we recall an idea constructing the homeomorphism which generates the Floyd’s cascade. As in [7] we consider $X$ as a subset of the square $[0, 1] \times [0, 1]$ in $\mathbb{R}^2$, $Y$ as a subset of the unit interval $[0, 1]$, and the map $\pi$ as the projection on the first coordinate. We let

$$X_0 = \{x \in X : \pi^{-1}(\pi(x)) = \{x\}, \quad Y_0 = \pi(X_0).$$

We know that the set $Y_1 = Y \setminus Y_0$ is countable and that for each $y \in Y_1$ the set $A_y = \pi^{-1}(y)$ is a non-degenerate vertical line segment over the point $y$. It is not hard to see that for each $p \in E(X, T)$, and such line segment $A_y$, the restriction of $p$ to $A_y$ is an affine map of $A_y$ onto a closed subinterval of $A_{py}$, if $py \in Y_1$, and into...
the singleton $\pi^{-1}(py)$ if $py \in Y_0$. As a consequence we see that for $y \in Y_1$, the map $p \upharpoonright A_y$ is determined by the values of $p$ at any two distinct points of $A_y$. Choose a set $C \subset X_1 = X \setminus X_0$ such that for each $y \in Y_1$ we have that $C \cap A_y$ is a countable set which is dense in $A_y$. Of course $C$ is a countable set.

Now given $p \in E(X,T)$, let $C_p = \{x \in X : px \in C\}$. We observe that, because $p$ restricted to a non-degenerate vertical segment which is mapped by $p$ onto a non-degenerate vertical segment, is an affine map (hence one-to-one) $C_p$ is a countable set. We will show that $p$ is determined by its values on $C_p$; i.e. if $q \in E(X,T)$ is such that $p \upharpoonright C_p = q \upharpoonright C_p$ then $p = q$. We first note that $E(Y,T) = Y$ is an abelian group and by Remark 1.3.2 any single element of $E(Y)$ is completely determined by its value at any single point $y$ of $Y$. So, $p$ and $q$ have the same image in $E(Y,T)$. It then follows that $px = qx$ for all $x \in X_0$. So we now assume that $x \in X_1 = X \setminus X_0$.

**Case 1:** $px \notin C$. Then $\pi^{-1}(\pi(px)) = \{px\}$ and, since $\pi(px) = \pi(qx)$, we have $qx = px$.

**Case 2:** $px \in C$; i.e. $x \in C_p$, hence $y = \pi(px) \in Y_1$ and $A_y$ is a non-degenerate interval. Let $z = \pi(x)$, which by assumption is in $Y_1$. Thus $A_z$ is a non-degenerate interval containing $x$.

**Case 2a:** $pA_z = \{px\} \subset A_y$ is a singleton. It then follows that also $qA_z = \{px\}$, hence $qx = px$.

**Case 2b:** $pA_z \subset A_y$ is a non-degenerate interval. In this case $|pA_z \cap C| = \infty$ and there are distinct points $x_1, x_2 \in A_z$ so that $px_1$ and $px_2$ are distinct points of $pA_z \cap C$. In particular $x_1, x_2 \in C_p$ and by assumption $qx_1 = px_1$ and $qx_2 = px_2$. As both $p \upharpoonright A_z$ and $q \upharpoonright A_z$ are affine maps, it follows that $p \upharpoonright A_z = q \upharpoonright A_z$ and, in particular $qx = px$.

Thus we have shown that indeed $p = q$, and the countable set $C_p$ determines $p$. Applying Proposition 1.2 we deduce that $E(X,T)$ is first countable, and hence also that $(X,T)$ is tame. \qed

**Example 2.6.** In a beautiful work [5], Aujogue gives a complete description of the enveloping semigroup of a large class of cut and project $\mathbb{R}^d$ systems called **almost canonical model sets** (which play a major role in mathematical models of quasicrystals). These are almost automorphic $\mathbb{R}^d$ actions obtained by the cut and project scheme, from a lattice $\Sigma$ in $\mathbb{R}^n \times \mathbb{R}^d$ with a window $W \subset \mathbb{R}^n$, which is a polytope satisfying certain conditions. In particular Aujogue shows that these systems are tame with a first countable enveloping semigroup. See also [6].

The interested reader will find many more examples of tame and non-tame almost automorphic systems in the recent works [28], [27].

### 3. Asymptotic extensions

Recall that the **adherence semigroup** $\text{Adh}(X,T)$ of a dynamical system $(X,T)$ is the set of accumulation points of $T$ in $E(X,T)$. It is the semigroup $E(X,T) \setminus T$ iff $T$ forms an open dense subset of $E(X,T)$, iff $(X,T)$ is not weakly rigid (see [8] and Section 3 below). An extension $\pi : (X,T) \to (Y,T)$ of minimal systems is called **asymptotic** if $R_\pi \subset \text{ASYM}$, where

$$R_\pi = \{(x,x') \in X \times X : \pi(x) = \pi(x')\},$$
and

\[
ASYM = \{(x, x') \in X \times X : px = px', \ \forall p \in \text{Adh} (X, T)\}.
\]

By [3, Theorem 6.29] an asymptotic extension is irreducible and, when \(X\) is metrizable, it is an almost one-to-one extension. If in addition the system \((Y, T)\) is equicontinuous, then \((X, T)\) is almost automorphic. Note that the Floyd system is not an asymptotic extension of its maximal equicontinuous factor (it has, for example, infinitely many fibers of length 1/2).

**Theorem 3.1.** Let \((X, T)\) be a minimal metric system, with \(T\) an abelian group. Suppose further that it is AA\(_c\), and that the extension \(\pi: X \to Y\), where \(Y\) is the largest equicontinuous factor of \(X\), is asymptotic. Then \(X\) is tame\(_1\).

**Proof.** Let \(\pi: (X, T) \to (Y, T)\) be the largest equicontinuous factor of \((X, T)\), so that \(\pi\) is an almost one-to-one extension. By assumption the set

\[
Y_m = \{y \in Y : |\pi^{-1}(y)| > 1\}
\]

is at most countable. Let

\[
X_m = \pi^{-1}(Y_m),
\]

\[
X_0 = \{x \in X : \pi^{-1}(\pi(x)) = \{x\}\} = X \setminus X_m,
\]

and

\[
Y_0 = \pi(X_0) = \{y \in Y : |\pi^{-1}(y)| = 1\} = Y \setminus Y_m.
\]

If \(X_0 = X\), the system \((X, T)\) is equicontinuous and \(E(X, T) \cong (X, T)\) is metrizable. So we now assume that \(X_0 \subset X\), in which case it is a dense \(G_\delta\) subset of \(X\). We recall that the map \(\pi\) induces a surjective (dynamical and semigroup) homomorphism \(\pi_*: E((X, T) \to E(Y, T)\). In our case, as \((Y, T)\) is minimal, metric, equicontinuous and \(T\) is abelian, \(E(Y, T) \cong (Y, T)\) is a second countable compact abelian topological group. We have \(\pi(px) = \pi_*(p)\pi(x)\) \((x \in X, p \in E(X, T))\). For simplicity we will dispense with the symbol \(\pi_*\) and write this as \(\pi(px) = p\pi(x)\). Note that then, considering \(p\) as an element of the group \(E(Y, T)\), it has an inverse and the notation \(p^{-1}y\) for \(y \in Y\) makes sense. Now given \(p \in E(X, T)\) choose \(C(p) \subset \pi^{-1}(p^{-1}Y_m)\) such that

\[
\begin{align*}
|C(p) \cap \pi^{-1}(y)| &= 1, & \text{if } y \in p^{-1}Y_m \cap Y_0 \\
|C(p) \cap \pi^{-1}(y)| &= 2, & \text{if } y \in p^{-1}Y_m \setminus Y_0.
\end{align*}
\]

We write \(C(p) = C_1 \cup C_2\) where the sets \(C_1, C_2\) are determined by the conditions in (3.1).

Suppose now that \(q \in E(X, T)\) is such that \(q \upharpoonright C(p) = p \upharpoonright C(p)\); we claim that \(p = q\). Let \(x\) be any point in \(X\) and let \(y = \pi(x)\). As \(C(p)\) is nonempty our assumption implies that \(p\) and \(q\) define the same element of the group \(E(Y, T)\). Thus if \(px \in X_0\) then clearly \(px = qx\). So we now assume that \(px \in X_m\), and it then follows that \(x \in \pi^{-1}(p^{-1}Y_m)\). If \(y \in p^{-1}Y_m \cap Y_0\) then \(\pi^{-1}(y) = \{x\}\) and we have \(qx = px\). Otherwise, \(y \in p^{-1}Y_m \setminus Y_0\) and \(\pi^{-1}(y)\) is not a singleton. We have to consider two cases.

In case \(p \in \text{Adh}(X, T) = E(X, T) \setminus T\), then the assumption that \(\pi\) is an asymptotic extension implies that \(p\pi^{-1}(y) = p(\pi^{-1}x)\) is a singleton, say \(\{z\}\), and then \(px = z = px_1 = px_2\), where \(\{x_1, x_2\} = C_2 \cap \pi^{-1}(y)\), hence \(z = px_1 = qx_1 = px_2 = qx_2\). It follows that also \(q \in \text{Adh}(X, T) = E(X, T) \setminus T\), hence \(qx = px = z\). Finally if \(p \in T\) then
\( qx_1 = px_1 \neq px_2 = qx_2 \), therefore also \( q \in T \), whence \( p = q \). In view of Proposition 1.2 our proof is complete. \( \square \)

Now the class of dynamical systems satisfying the conditions of Theorem 3.1 is very large. It contains e.g. all the Sturmian like systems and many other semi-cocycle extensions (see subsection 3.1 below). We demonstrate this with the following construction.

**Example 3.2.** Here is a simple construction of a minimal cascade \((X, T)\) on a Cantor set with a factor map \( \pi: X \to Y \) such that \( N(y) := \text{card } \pi^{-1}(y) < \omega \) for all \( y \in Y \) but \( N(\cdot) \) is not bounded.

Start with an adding machine (or any other minimal system on a Cantor set), say \((Y, S)\). Choose a convergent sequence of distinct points \( \{y_n\}_{n=1}^{\infty} \) in \( Y \), with \( \lim_{n \to \infty} y_n = y_{\infty} \notin \{y_n\}_{n \in \mathbb{N}} \), such that the orbits \( O_S(y_i) \), \( i = 1, 2, \ldots, \infty \), are all distinct. Construct by induction a sequence of disjoint clopen neighborhoods \( V_n \ni y_n \), \( n < \infty \). Choose for each \( n \) a nesting sequence of clopen sets \( B_{n,k}, \) neighborhoods of \( y_n \), with \( B_{n,1} \subset V_n \) and \( \lim_{k \to \infty} \text{diam } B_{n,k} = 0 \). Next define a function \( f: Y \to [0, 1] \) as follows. For a fixed \( n < \infty \) let \( f = \frac{1}{n^2} \) on \( B_{n,k} \setminus B_{n,k+1} \) where \( 0 \leq j \leq n - 1 \) and \( j \equiv k \pmod{n} \). On the rest of the space put \( f = 0 \). Clearly \( f \) is continuous on the complement of \( \{y_1, y_2, \ldots\} \). In particular \( f \) is continuous at \( y_{\infty} \).

Let \( y_0 \in Y \) be a point of continuity of \( f \) outside of \( \{y_n\}_{n=1}^{\infty} \cup \{y_{\infty}\} \), and let \( X \) be the closure of the orbit of \((y_0, \{f(S^jy_0)\}_{-\infty<j<\infty}) \) in \( Y \times [0, 1]^Z \), where on \([0, 1]^Z\) the action is the shift \( \sigma \), and \( T \) is defined as the restriction to \( X \) of the product \( S \times \sigma \).

It is not hard to verify that \( \pi: X \to Y \), the projection on the first coordinate, has the property \( \text{card } \pi^{-1}(S^jy_k) = k \), for \( k = 1, 2, \ldots, j \in \mathbb{Z} \), and that \( \text{card } \pi^{-1}(y) = 1 \) for any other point \( y \in Y \). As a point transitive almost 1-1 extension of \( Y \), the system \((X, T)\) is minimal.

When we start with \((Y, S)\) which is an adding machine, it is easy to check, that the system \((X, T)\) is tame and that the extension \( \pi \) is asymptotic. We thus obtain a metric tame system \((X, T)\) with \( E(X, T) \) first countable.

Similar constructions will yield many other examples of this type with, say, \( |\pi^{-1}(y)| = \aleph_0 \) or \( \pi^{-1}(y) = [0, 1] \), for some \( y \in Y \); or in fact, given any compact separable space \( \Omega \), we can build such an example with \( \pi^{-1}(y) = \Omega \) for some \( y \in Y \). See [63, Example 5.7] for such constructions.

**Remark 3.3.** In Section 9, Theorem 9.1 we will show that, e.g. when \( T \) is abelian, the condition AA\(_c\) suffices to ensure that if \((X, T)\) is a minimal metric tame system, then the unique minimal left ideal \( M \) in \( E(X, T) \) is a first countable Rosenthal compactum.

### 3.1. Semi-cocycles

Let \( T \) be a discrete countable group. Let \((Y, T)\) be a metric minimal infinite dynamical system and let \( K \) be a compact space. Let \( C \subset Y \) be a nonempty finite or countable set. Let \( F: X \setminus C \to K \) be a continuous map. Such a function is called a semi-cocycle in [17], [10]. We refer to [18] and the recent [28] for the theory of semi-cocycles, whose roots can be traced to [29].

We further assume that for each \( c \in C \) the function \( F \) can not be extended continuously to \( c \), and that **for every** \( c \in C \) **the set** \( TC \cap C \) **is finite.**
We fix a point \( y_0 \in X \setminus C \) and set \( f(t) = F(ty_0) \), a function in \( \Omega = K^\mathbb{T} \). Let \( x_0 \in Y \times K^\mathbb{T} \) be defined by
\[
x_0(t) = (y_0, F(ty_0)) = (y_0, f(t)), \quad t \in T.
\]
For \( t \in T \) let \( T_t: Y \times \Omega \to Y \times \Omega \) be defined by
\[
T_t(y, \omega) = (ty, S_t \omega),
\]
where for \( \omega \in \Omega \) the shift homeomorphism \( S_t: \Omega \to \Omega \) is defined by \( S_t \omega(s) = \omega(st) \).

Let
\[
X = \text{cls} \Omega_T(x_0) = \{ T_t x_0 : t \in T \} \subset Y \times \Omega.
\]
We let \( \pi: X \to Y \) denote the projection on the \( Y \) coordinate. Clearly \( \pi: (X,T) \to (Y,T) \) is a homomorphism of dynamical systems. One can also easily see that \( \pi \) is an almost one-to-one extension, with \( \pi^{-1}(\pi(x)) = \{ x \} \) for every \( x \) with \( \pi(x) \not\in T \). In fact, for such \( x \) and for a sequence \( t_i \) such that \( \lim_i t_i y_0 = \pi(x) = y \not\in T \), we have:
\[
\lim_{i \to \infty} T_{t_i} x_0 = x, \quad \text{with} \quad x(t) = (y, F(ty)), \quad (t \in T).
\]
It then follows that the system \((X,T)\) is minimal and almost automorphic of type \( \text{AA}_c \).

Next fix a point \( c \in C \) and let \( t_i \) be a sequence in \( T \) such that \( x = \lim T_{t_i} x_0 \) with \( \pi(x) = c \). We then have
\[
x(t) = \lim_{i \to \infty} (T_{t_i} x_0)(t) = \lim_{i \to \infty} (t_i y_0, F(t_i)) = \lim_{i \to \infty} (t_i y_0, F(t_i y_0)) = (c, k(t)), \quad (t \in T)
\]
with \( k(t) = \lim_{i \to \infty} F(t_i y_0) \in K \).

The element \( k(t) \) may depend on \( t \), but, by our assumption that \( Tc \cap C \) is finite, we now see that any two points in \( \pi^{-1}(c) \) may differ in at most finitely many coordinates. The same of course holds for \( \pi^{-1}(tc) \) for every \( t \in T \). Thus the map \( \pi \) is asymptotic, so that the conditions in Theorem [3.1] are fulfilled. We have proved the following:

**Proposition 3.4.** Let \( F \) be a semi-cocycle as above. Then the map \( \pi \) is an asymptotic extension, whence (by Theorem [3.1]) the system \((X,T)\) is tame\(_1\).

4. **A tame\(_1\) almost automorphic system which is not tame\(_2\)**

**Proposition 4.1.**

1. There exists a tame\(_1\) almost automorphic \( \mathbb{Z} \)-system which is not tame\(_2\).
2. There are two disjoint minimal tame\(_2\) systems whose product (which is minimal and tame\(_1\)) is not tame\(_2\).

**Proof.** Let \( T = \mathbb{R}/\mathbb{Z} \) be the one-dimensional torus, and let \( \alpha \in \mathbb{R} \) be a fixed irrational number and \( T_\alpha: \mathbb{T} \to \mathbb{T} \) is the rotation by \( \alpha \), \( T_\alpha \theta = \theta + \alpha \) (mod 1). We define a topological space \( X = T_\alpha \mathbb{T} \) and a continuous map \( \pi: X \to T \) as follows. Intuitively, \( T_\alpha \mathbb{T} \) is a circularly ordered space which we get by splitting on the circle \( \mathbb{T} \) the points of the orbit \( A := \{ n\alpha : n \in \mathbb{Z} \} \). Then the map \( \pi: X \to \mathbb{T} \) is just the natural projection (gluing back the splitted points). For \( \theta \in \mathbb{T} \setminus \{ n\alpha : n \in \mathbb{Z} \} \) the preimage \( \pi^{-1}(\theta) \) is a singleton \( x_\theta \). On the other hand for each \( n \in \mathbb{Z} \), \( \pi^{-1}(n\alpha) \) consists of exactly two points \( x_{n\alpha}^- \) and \( x_{n\alpha}^+ \). For convenience we will use the notation \( \theta^\pm \) (\( \theta \in \mathbb{T} \)) for points of \( X \), where \( (n\alpha)^- = x_{n\alpha}^- \), \( (n\alpha)^+ = x_{n\alpha}^+ \) and \( \theta^- = \theta^+ = x_\theta \) for \( \theta \in \mathbb{T} \setminus \{ n\alpha : n \in \mathbb{Z} \} \). A
basis for the topology at a point of the form $x_{\theta}, \theta \in \mathbb{T}\setminus\{n\alpha : n \in \mathbb{Z}\}$, is the collection of sets $\pi^{-1}(\theta - \epsilon, \theta + \epsilon), \epsilon > 0$. For $(n\alpha)^-$ a basis will be the collection of sets of the form $\{(n\alpha)^-\} \cup \pi^{-1}(n\alpha - \epsilon, n\alpha)$, where $\epsilon > 0$. Finally for $(n\alpha)^+$ a basis will be the collection of sets of the form $\{(n\alpha)^+\} \cup \pi^{-1}(n\alpha, n\alpha + \epsilon)$. It is not hard to check that this defines a compact metrizable zero dimensional topology on $X$ (in fact $X$ is homeomorphic to the Cantor set) with respect to which $X$ is a minimal system.

We now define for each $\gamma \in \mathbb{T}$ two distinct maps $p_\gamma^\pm : X \to X$ by the formulas

$$p_\gamma^+(\theta^\pm) = (\theta + \gamma)^+, \quad p_\gamma^-(\theta^\pm) = (\theta + \gamma)^-.$$ 

We leave the easy verification of the following claims to the reader.

1. For every $\gamma \in \mathbb{T}$ and every sequence, $n_i \nearrow \infty$ with

$$\lim_{i \to \infty} n_i \alpha = \gamma,$$

we have $\lim_{i \to \infty} T^{n_i} = p_\gamma^+$ in $E(X, T)$. An analogous statement holds for $p_\gamma^-$. 

2. $E(X, T) = \{T^n : n \in \mathbb{Z}\} \cup \{p_\gamma^+: \gamma \in \mathbb{T}\}$

3. The subspace $\{T^n : n \in \mathbb{Z}\}$ inherits from $E$ the discrete topology.

4. The adherence semigroup

$$\text{Adh}(X, T) = E(X, T) \setminus \{T^n : n \in \mathbb{Z}\} = \{p_\gamma^+: \gamma \in \mathbb{T}\}$$

is homeomorphic to the “two arrows” space of Alexandroff and Urysohn (see [23] page 212, and also to Ellis’ “two circles” example [20] Example 5.29). It thus follows that $E$ is a separable Rosenthal compactum of cardinality $2^{\aleph_0}$.

5. For each $\gamma \in \mathbb{T}$ the complement of the set $C(p_\gamma^\pm)$ of continuity points of $p_\gamma^\pm$ is the countable set $\{\theta^\pm : \theta + \gamma = n\alpha, \text{ for some } n \in \mathbb{Z}\}$. In particular, each element of $E$ is of Baire class 1.

Algebraically

$$\text{Adh}(X, T) = \{p_\gamma^+: \gamma \in \mathbb{T}\} = \mathbb{T} \times \{1, -1\}$$

and it can be checked that its topology is separable and first countable. Each of the two components $\mathbb{T} \times \{1\}$ and $\mathbb{T} \times \{-1\}$ is dense, and with the induced topology, it is the Sorgenfrey circle. These components though are highly non-measurable sets. Dynamically $M = \text{Adh}(X, T)$ is the unique minimal left ideal of $E(X, T)$ and thus a minimal system (see Section 9 below).

Next let $\beta \in \mathbb{R}$ be an irrational number such that the pair $(\alpha, \beta)$ is independent over the rational numbers. We consider the dynamical system $(Y, T)$ which is obtained as above from $(\mathbb{T}, R_\beta)$. The two systems $(X, T)$ and $(Y, T)$ are then disjoint, which means that the product system $(X \times Y, T \times T)$ is minimal. It then follows that also the two minimal systems $\text{Adh}(X, T)$ and $\text{Adh}(Y, T)$ are disjoint, so that the system

$$\Omega = \text{Adh}(X, T) \times \text{Adh}(X, T) \cong (\mathbb{T} \times \{1, -1\}) \times (\mathbb{T} \times \{1, -1\})$$

is a minimal system.

Given $r \in E(X \times Y, T \times T)$ we let $(p, q) = (p_r, q_r) \in E(X, T) \times E(Y, T)$ be its canonical image in $E(X, T) \times E(Y, T)$. This then defines a homomorphism of $\text{Adh}(X \times Y, T \times T)$ into $\Omega = \text{Adh}(X, T) \times \text{Adh}(X, T)$ which is clearly injective. Conversely, given a pair $(p, q) \in \text{Adh}(X, T) \times \text{Adh}(X, T)$ there is, by minimality,
an \( r \in \text{Adh}(X \times Y, T \times T) \) with \( r(\text{Id}_X, \text{Id}_Y) = (p, q) \). Thus our homomorphism is also surjective, i.e. an isomorphism of \( \text{Adh}(X \times Y, T \times T) \) and \( \Omega = \text{Adh}(X, T) \times \text{Adh}(X, T) \).

It is now easy to check that the subset
\[
\Omega_0 = (\mathbb{T} \times \{1\}) \times (\mathbb{T} \times \{-1\}) \subset \Omega
\]
is a copy of the Sorgenfrey torus and that its subset
\[
\Delta = \{ (p_\gamma^+, p_\gamma^-) : \gamma \in \mathbb{T} \}
\]
hits the discrete topology from \( \Omega \).

Thus our system \((X \times Y, T \times T)\) is
- a metric minimal \(\mathbb{Z}\)-system,
- almost automorphic (over the 2-torus \((\mathbb{T} \times \mathbb{T}, R_\alpha \times R_\beta)\)),
- tame \((E(X \times Y, T \times T)\) is a Rosenthal compactum),
- \(E(X \times Y, T \times T)\) is first countable (e.g. by Theorem 3.1),
- and \(E(X \times Y, T \times T)\) is not hereditarily separable.

This completes our proof. \(\square\)

**Remark 4.2.** As we have shown \(\text{Adh}(X \times Y)\) is the topological square of the two arrows space. Note that it contains the Alexandroff duplicate \(D([0, 1]^\mathbb{N})\) of the Cantor set.

It is equivalent to showing that the square \(S^2\) of the split interval \(S := S([0, 1])\) contains \(D([0, 1]^\mathbb{N})\) (here \(S := \{p^\pm : p \in [0, 1]\} \) and \(p^- < p^+\)). In order to see this consider the Cantor set \(C \subset [0, 1]\) and define in \(S^2\) the following subset
\[
Y := \{ (p^+, (1-p)^+) : p \in C \} \cup \{ (p^-, (1-p)^+) : p \in C \}.
\]
Then \(Y\) is homeomorphic to \(D([0, 1]^\mathbb{N})\). The “positive half” \(\{ (p^+, (1-p)^+) : p \in C \}\) is a discrete subset of \(Y\).

## 5. Weak rigidity

A dynamical system \((X, T)\) (where we assume that the \(T\)-action is effective) is said to be **weakly rigid** when \(\text{Adh}(X, T) = E(X, T)\) or equivalently when there is a net \(\{t_i\} \subset T \setminus \{e\}\) with \(t_i \to \text{Id}\) (pointwise on \(X\)). It is called **rigid** when there is a sequence \(\{t_i\} \subset T \setminus \{e\}\) with \(t_i \to \text{Id}\) (pointwise on \(X\)). Finally \((X, T)\) is **uniformly rigid** when the convergence of the sequence \(\{t_i\}\) to \(\text{Id}\) is uniform. Note that a system \((X, T)\) is not weakly rigid when and only when \(T\) is an open dense subset of \(E(X, T)\).

The following claim follows directly from the fact that the enveloping semigroup of a metric tame system is a Fréchet-Urysohn topological space (Theorem 0.5).

**Proposition 5.1.** A tame system is weakly rigid if and only if it is rigid.

**Proposition 5.2.** For any dynamical system \((X, T)\), weak rigidity implies that
\[
\text{Asym}(X, T) = \Delta.
\]

**Proof.** Suppose \((X, T)\) is weakly rigid and let \((x, x')\) be an asymptotic pair. Let \(\{t_i\} \subset T \setminus \{e\}\) be a net such that \(t_i \to \text{Id}\). Then
\[
x = \lim t_i x, \quad x' = \lim t_i x'
\]
and \( \lim t_i x = \lim t_i x' \), whence \( x = x' \).

\( \square \)

**Example 5.3.** (See [36, 46] and [2])

1. Every distal system is weakly rigid.
2. Every WAP cascade is uniformly rigid.
3. There are minimal weakly mixing uniformly rigid cascades.

**Example 5.4.** The Glasner-Weiss examples (see [37, theorem 11.1]) are uniformly rigid cascades which are HNS hence tame. These systems are metric, not equicontinuous and not minimal. Being HNS their enveloping semigroups are actually metrizable (see [45]).

**Example 5.5.** In [47] the authors show that their ‘Auslander systems’ (a family of almost automorphic systems which generalize the Floyd system) is never weakly rigid.

**Question 5.6.**

1. Is there an example of a tame rigid (metric, cascade) system \((X,T)\) which is not HNS (i.e. with non-metrizable enveloping semigroup)?
2. Is there a minimal, tame, rigid system \((X,T)\) which is not equicontinuous?

**Example 5.7.** In [21] the author shows that the action of \( G = \text{GL}(d,\mathbb{R}) \) on the projective space \( \mathbb{P}^{d-1} \), \( d \geq 2 \), is tame and that the corresponding enveloping semigroup \( E(\mathbb{P}^{d-1},G) \) is not first countable. He also shows that the group \( G \) embeds as an open subset of \( E(\mathbb{P}^{d-1},G) \). Thus this action is not weakly rigid.

The system in the following example is a (two-to-one) extension of the system from Example 5.7. This demonstrates that the class \( \text{Tame}_1 \) is not closed under factors.

**Example 5.8.** [1] The sphere \( \mathbb{S}^{d-1} \) with the projective action of the group \( G = \text{GL}(d,\mathbb{R}) \) (or, of the projective group \( \text{PGL}(d,\mathbb{R}) \)) is tame but not tame 2.

**Example 5.9.** Let \( G = \text{GL}(d,\mathbb{R}) \) and \( X_1 = \mathbb{S}^{d-1}, X_2 = \mathbb{P}^{d-1} \). Set \( X = X_1 \cup X_2 \), the disjoint sum of \( G \)-systems. The dynamical system \((X,G)\) is tame and, as the system \((X_2,G)\) is a factor of \((X_1,G)\), we have \( E(X,G) = E(X_1,G) \). We see that the tame 1 system \((X,G)\) admits a subsystem, namely \((X_2,G)\), which is not tame 1. Thus the class \( \text{Tame}_1 \) is not closed under subsystems.

6. **On tame dynamical systems which are not \( \text{Tame}_1 \)**

Let \((X,T)\) be a dynamical system with enveloping semigroup \( E = E(X,T) \). Let us call an element \( p \in E \) a parabolic idempotent with target \( x_0 \) if there is a point \( x_0 \in X \) such that \( px = x_0, \forall x \in X \), and a loxodromic idempotent with target \((x_0,x_1)\) if there are distinct points \( x_0, x_1 \in X \) with \( px = x_0, \forall x \in X \setminus \{x_1\} \) and \( px_1 = x_1 \). We say that \( x_0 \) and \( x_1 \) are the attracting and repulsing points of \( p \) respectively. Clearly, if \((X,T)\) admits a parabolic idempotent, it is necessarily a proximal system and therefore contains a unique minimal set \( Z \subseteq X \). If \((X,T)\) is a proximal system then every minimal idempotent is parabolic with target at the minimal set (and of course conversely, every parabolic idempotent whose target is in the minimal subset of \( X \) is a minimal idempotent).
Proposition 6.1. Let \((X,T)\) be a proximal dynamical system. Let \(Z \subset X\) be its (necessarily unique) minimal subset.

1. Suppose that there is an uncountable set \(B \subset X\) such that for each \(b \in B\) there is a loxodromic idempotent \(p_b\) with target \((a_b, b)\), with \(b\) as a repulsing point and \(a_b \in Z\) the attracting point such that \(b \neq a_b\). Then \(E(X,T)\) contains the uncountable discrete subset \(\{p_b : b \in B\}\), hence it is not hereditarily separable.

2. Suppose there is a point \(a \in Z\) and an uncountable set of points \(B = \{b_\nu\} \subset X\setminus \{a\}\) such that each pair \((a, b_\nu)\) is the target pair of a loxodromic idempotent \(p_{(a,b_\nu)}\) with attracting point \(a\) and a repulsing point \(b_\nu\). Then the parabolic idempotent \(p_a\) defined by \(p_a x = a, \forall x \in X\), does not admit a countable basis for its topology, hence \(E(X,T)\) is not first countable.

Proof. (1) Straightforward.

(2) We repeat Ellis’ argument in [21] as follows: Assuming otherwise, in view of Lemma 1.2, there is a countable set \(C \subset X\) such that for any \(q \in E(X,T)\), if \(qc = p_a c\) for every \(c \in C\) then \(q = p_a\). Now the set \(B\) is uncountable and we can choose an element \(b_\nu \in B \setminus C\). It then follows that for every \(c \in C\) we have

\[ p_{(a,b_\nu)} c = p_a c = a, \]

but nonetheless \(p_{(a,b_\nu)} b_\nu = b_\nu \neq a = p_a b_\nu\). Thus \(p_{(a,b_\nu)} \neq p_a\), a contradiction. \(\square\)

Remark 6.2. The subset \(\{p_a\} \cup B\) of \(X\) is a topological copy of the Alexandroff compactification \(A(c)\), of a discrete space of size continuum. Note that, in view of Theorem 0.3, the existence of a copy of \(A(c)\) in \(E(X)\) is another way of seeing that \((X,T)\) is not tame (see additional cases where Proposition 6.1(2) applies, in Theorem 6.5, Theorem 7.1 and Proposition 8.10).

Let \(\Gamma\) be an infinite countable uniform convergence group acting on a compact metric space \(X\) with infinite limit set \(\Lambda \subset X\). Then the system \((\Lambda, \Gamma)\) is minimal and every point of \(\Lambda\) is conical (see [13, Proposition 3.3]).

Definition 6.3. A point \(b \in \Lambda\) is a conical limit point if there is a wandering net, \(\gamma_n \in \Gamma\), such that for all \(y \in \Lambda \setminus \{b\}\), the ordered pairs \((\gamma_n b, \gamma_n y)\) lie in a compact subset of the space of distinct pairs of \(\Lambda\).

Claim 6.4. The following conditions are equivalent for a point \(b \in \Lambda\):

1. It is a conical point.
2. There is a collapsing sequence \(\gamma_n\) and a point \(a \in \Lambda\) with \(\gamma_n y \to a\) for all \(y \in \Lambda \setminus \{b\}\) and \(\gamma_n b \to b\).
3. There is a point \(y \in X, y \neq b\) and there are nets \(x_n \in X \setminus \{b, y\}\) with \(x_n \to b\), and \(\gamma_n \in \Gamma\), such that the sequence \(\gamma_n (b, y, x_n)\) remains in a compact subset of \(\Theta^0(X)\).
4. The point \(b\) is the repulsing point for a loxodromic projection \(p \in E(X, \Gamma)\).

Theorem 6.5. Let \(\Gamma\) be an infinite countable uniform convergence group acting on a compact metric space \(X\) with infinite limit set \(\Lambda \subset X\). Then the dynamical system \((X, \Gamma)\) is tame but \(E(X, \Gamma)\)

(i) is not hereditarily separable; in fact it contains a subset of cardinality \(2^{\aleph_0}\) which is discrete in the relative topology.
(ii) is not first countable.

Proof. The fact that \((X, \Gamma)\) is tame follows directly from the definition of being a divergence group. In \cite{52} the authors show, with a direct simple argument, a stronger statement, namely that it is null.

(i) As every point of \(X\) is conical, for each \(b \in X\) let \(p_b\) be a loxodromic idempotent, say with repulsing point \(b\). It is easy to check that every limit point of the collection \(B = \{p_b : b \in X\}\) is parabolic. Thus the topology induced on \(B\) from \(E(X, \Gamma)\) is discrete (by Proposition 6.1).

(ii) By \cite[Corollary 1.2.2]{30} every minimal proximal system is weakly mixing; i.e. the product system \(X \times X\) is topologically transitive, and \(X\) being a metric space, the set of transitive points

\[
A = \{(x, y) \in X \times X : \Gamma(x, y) = X \times X\}
\]

is a dense \(G_\delta\) subset of \(X \times X\). We then conclude, by the theorem of Kuratowski and Ulam, that there is a residual subset \(D\) of \(X\) such that for every \(x \in D\) the set \(A_x = \{y \in X : (x, y) \in A\}\) is residual in \(X\). In particular, \(A_x\) is of cardinality \(2^{\aleph_0}\).

Fix a point \((x_0, y_0) \in A\) and let \((z, w)\) be an arbitrary point in \(X \times X\) with \(z \neq w\). There is a sequence \(\gamma_n \in \Gamma\) with \(\gamma_n(x_0, y_0) \to (z, w)\). We can assume that \(\gamma_n\) is a collapsing sequence and then we have a pair \((a, b) \in X \times X\) such that \(\gamma_n x \to a\) for every \(x \in X \setminus \{b\}\) and \(\gamma_n b \to b\). Let \(p_{(a,b)}\) denote the corresponding idempotent in \(E(X, \Gamma)\). Thus \(p_{(a,b)} x = a\) for every \(x \in X \setminus \{b\}\) and \(p_{(a,b)} b = b\).

It then follows that either \(z = \lim \gamma_n x_0 = a\) and \(w = \lim \gamma_n b = b\), or \(z = \lim \gamma_n x_0 = b\) and \(w = \lim \gamma_n = a\). Of course, by replacing \(\gamma_n\) by \(\gamma_n^{-1}\), we can assume with no loss of generality that the first case occurs.

As a consequence of this discussion we conclude that:

- For every \(a \in D\) there is a residual set of points \(B_a = \{b_a\} \subset X \setminus \{a\}\) such that each pair \((a, b_a)\) is the target pair of a loxodromic idempotent \(p_{(a,b_a)}\) with attracting point \(a\) and a repulsing point \(b_a\).

Now apply Proposition 6.1 (2).

A Gromov hyperbolic group acting on its boundary is an example of a group satisfying the conditions of Theorem 6.5. In fact, it was shown by Bowditch \cite{14} that essentially these are the only examples: If an infinite countable group \(\Gamma\) is acting as a uniform convergence group on a compact perfect metric space \(X\) then, \(\Gamma\) is hyperbolic and the dynamical system \((X, \Gamma)\) is isomorphic to the action of \(\Gamma\) on its Gromov boundary.

**Corollary 6.6.** The action of a hyperbolic group \(\Gamma\) on its Gromov boundary \(\partial \Gamma\) is tame but not tame_1.

**Example 6.7.** (Dynkin and Maljutov \cite{19}) The free group \(F_2\) on two generators, say \(a\) and \(b\), is hyperbolic and its boundary can be identified with the compact metric space \(\Omega\) (a Cantor set) of all the one-sided infinite reduced words \(w\) on the symbols \(a, b, a^{-1}, b^{-1}\). The group action is

\[
F_2 \times \Omega \to \Omega, \quad (\gamma, w) = \gamma \cdot w,
\]

where \(\gamma \cdot w\) is obtained by concatenation of \(\gamma\) (written in its reduced form) and \(w\) and then performing the needed cancelations (see \cite{19}). The resulting dynamical system
is tame (in fact, null), and the enveloping semigroup $E(\Omega, F_2)$ is Fréchet-Urysohn but not first countable.

**Question 6.8.** Suppose $T$ is abelian (or even more specifically that $T = \mathbb{Z}$). Is there a tame metric (minimal) system $(X, T)$ such that $E(X, T)$ is not first countable?

7. Linear actions on Euclidean spaces

For many important actions $T \times X \to X$ the phase space is not compact. One may still study the tameness of this action via $T$-compactifications of $X$. It is especially natural whenever $X$ is locally compact. Since $T$-factors preserve the class $\text{Tame}$ (but not $\text{Tame}_1$) the question can be reduced to the case of the one-point $T$-compactification of $X$.

**Theorem 7.1.** Every linear action $\text{GL}(n, \mathbb{R}) \times \mathbb{R}^n \to \mathbb{R}^n$ is tame but, for $n \geq 2$ it is not tame$_1$.

**Proof.** Let $X_n := \mathbb{R}^n \cup \{\infty\}$ be the one point compactification of $\mathbb{R}^n$ and $G \times X_n \to X_n$, with $G = \text{GL}(n, \mathbb{R})$, be the canonical extension. We have to show that $X_n$ is a tame $G$-system. For $p \in E(X, G)$ let

$$V_p := p^{-1}(\mathbb{R}^n) = \{v \in \mathbb{R}^n : p(v) \in \mathbb{R}^n\} = \{v \in X : p(v) \neq \infty\}.$$

**Claim:** The subset $V_p$ is a linear subspace (hence, closed) in $\mathbb{R}^n$ and the restriction $p \upharpoonright V_p : V_p \to \mathbb{R}^n$ is a (continuous) linear map.

Indeed, let $g_i$ be a net in $G$ such that $\lim g_i = p$ in $E$. If $u, v \in V_p$ then $\lim g_i u = p(u) \in \mathbb{R}^n$ and $\lim g_i v = p(v) \in \mathbb{R}^n$. Then by the linearity of maps $g_i$ we obtain $\lim g_i (c_1 u + c_2 v) = c_1 p(u) + c_2 p(v) \in \mathbb{R}^n$. Since $V_p$ is finite dimensional, the linear map $p \upharpoonright V_p : V_p \to \mathbb{R}^n$ is necessarily continuous. \(\square\)

Using this claim we obtain that the cardinality of $E(X_n)$ is not greater than $2^{\aleph_0}$. Now the tameness follows by the dynamical BFT dichotomy (Theorem 0.5).

To see that $(X_n, G)$ is not tame$_1$ we first observe that the following lemma holds. The proof is by a verification of the conditions in Proposition 6.1 (2).

**Lemma 7.2.** Let $S < \text{GL}(2, \mathbb{R})$ be the subgroup

$$S = \left\{ \begin{pmatrix} a & b \\ 0 & 1 \end{pmatrix} : a > 0, \ b \in \mathbb{R} \right\}.$$

Then the action of $S$ on the space

$$Y_1 = \left\{ \begin{pmatrix} t \\ 1 \end{pmatrix} : t \in \mathbb{R} \right\} \cup \{\infty\} \subset \mathbb{R}^2 \cup \{\infty\}$$

is tame but not tame$_1$.

Denoting, for each $s \in \mathbb{R}$

$$Y_s = \left\{ \begin{pmatrix} t \\ s \end{pmatrix} : t \in \mathbb{R} \right\} \cup \{\infty\} \subset \mathbb{R}^2 \cup \{\infty\},$$

we have $X_2 = \bigsqcup_{s \in \mathbb{R}} Y_s$ and it follows that $E(X_2, S) = E(Y_1, S)$. 

Next observe that for any \( n \geq 2 \) the dynamical system \((X_2, S)\) is a subsystem of the system \((X_n, S)\) and we now consider \( S \) as a subgroup of \( GL(n, \mathbb{R}) \), embedded at the left top corner:

\[
A = \begin{pmatrix} a & b \\ 0 & 1 \end{pmatrix} \mapsto \begin{pmatrix} A & 0_{2,n-2} \\ 0_{n-2,2} & I_{n-2,n-2} \end{pmatrix}
\]

Moreover, as under this embedding the action of \( S \) on \( X_n \) has the property that it acts as the identity on the last \( n-2 \) coordinates of a vector in \( \mathbb{R}^n \), it follows that \( E(X_n, S) = E(X_2, S) = E(Y, S) \). Now, since \( E(X_n, S) \subset E(X_n, GL(n, \mathbb{R})) \) we conclude that \( E(X_n, GL(n, \mathbb{R})) \) is also not tame_1.

The following lemma presents another way of seeing that the action of \( GL(2, \mathbb{R}) \) on \( X_2 = \mathbb{R}^2 \cup \{ \infty \} \) is not tame_1.

**Lemma 7.3.** The action \( GL(2, \mathbb{R}) \times X_2 \to X_2 \) is not tame_1.

**Proof.** By Proposition 1.2 it is enough to show that there exists \( p \in E(X_2) \) such that countable subsets \( C(p) \) of \( X_2 \) cannot determine \( p \). Take the following \( \infty \)-idempotent

\[ p = p_\infty : X_2 \to X_2, \quad p(x) = \infty \forall x \neq 0_2 \text{ and } p(0_2) = 0_2. \]

It really belongs to \( E(X_2) \) because if \( t_n \in GL(2, \mathbb{R}) \) is the scalar matrix with \( t_n(x) = nx \) for every \( x \in \mathbb{R}^2 \), then \( \lim t_n = p \) in \( E(X_2) \). Let, as before, \( V_p := p^{-1}(\mathbb{R}^2) \). Then for such \( p \) we have \( V_p = \{0_2\} \). Assume in contrary that \( C(p) \) is a countable subset of \( X_2 \) which determines \( p \). We can suppose that \( C(p) \) does not contain \( 0_2 \) (and also \( \infty \)). There exists a one-dimensional subspace \( L \) in \( \mathbb{R}^2 \) which does not meet \( C(p) \). Moreover, there exists \( q_L \in E(X_2) \) such that \( q_L^{-1}(\mathbb{R}^2) = L \) and \( q_L(x) = x \) for every \( x \in L \). Up to a conjugation, we can suppose that

\[ L = \left\{ \begin{pmatrix} a \\ 0 \end{pmatrix} : a \in \mathbb{R} \right\}, \quad g_n = \begin{pmatrix} 1 & 0 \\ 0 & n \end{pmatrix}, \quad q_L = \lim g_n. \]

Then \( p(x) = q_L(x) = \infty \) for every \( x \in C(p) \) (but clearly, \( p \neq q_L \)).

**Remark 7.4.** The enveloping semigroup \( E(X_n) \) of the action from Theorem 7.1 can be identified with the semigroup of all partial linear endomorphisms of \( \mathbb{R}^n \). To see this observe that the claim from the proof of Theorem 7.1 can be reversed. Namely, every partial linear endomorphism \( f : V \to W \) of \( \mathbb{R}^n \) defines an element \( p \in E(X_n) \) such that

\[ V = p^{-1}(\mathbb{R}^n), \quad p(V) = W, \quad p(x) = f(x) \forall x \in V, \quad p(y) = \infty \forall y \notin V. \]

Moreover, that assignment is a semigroup isomorphism: (partial) composition corresponds to the product of suitable elements from the enveloping semigroup.

**Remark 7.5.** Theorem 0.3 predicts that \( E(X_2) \) in Lemma 7.3 should contain the Alexandroff compactification \( A(c) \), of a discrete space of size continuum. The following subset of \( E(X_2) \) is indeed a topological copy of \( A(c) \)

\[ \{ p_\infty \} \cup \{ q_L : L \text{ is a one-dimensional linear subspace in } \mathbb{R}^2 \}. \]
Lemma 7.6. The action of $S$ on the space

$$Y_1^* = \left\{ \begin{pmatrix} t \\ 1 \end{pmatrix} : t \in \mathbb{R} \right\} \cup \{ \pm \infty \}$$

is tame.1

Proof. Clearly every element $p \in \text{Adh} (Y_1^*, S)$ fixes the points $\pm \infty$. Suppose now that $p \in \text{Adh} (Y_1^*, S)$ satisfies $p \begin{pmatrix} s \\ 1 \end{pmatrix} = \begin{pmatrix} s \\ 1 \end{pmatrix}$ for some $s \in \mathbb{R}$. It is then easy to check that it has either the form $p^0_{0s}$ or $p^i_{0s}$, where for $s \in \mathbb{R}$,

$$p^0_{0s} \begin{pmatrix} t \\ 1 \end{pmatrix} = \begin{cases} \infty & t > s \\ s & t = s \\ -\infty & t < s, \end{cases}$$

$$p^i_{s} \begin{pmatrix} t \\ 1 \end{pmatrix} = \begin{pmatrix} s \\ 1 \end{pmatrix}$$

for all $t \in \mathbb{R}$.

Applying $g \in S$ with $g \begin{pmatrix} s \\ 1 \end{pmatrix} = \begin{pmatrix} r \\ 1 \end{pmatrix}$ we get the elements $gp^0_{0s} = p^o_{rs}$, where

$$p^o_{rs} \begin{pmatrix} t \\ 1 \end{pmatrix} = \begin{cases} \infty & t > s \\ r & t = s \\ -\infty & t < s, \end{cases}$$

and $gp^i_{s} = p^i_{r}$.

To complete the list of all the elements of $\text{Adh} (Y_1^*, S)$ we have to add the limits:

$$p_\infty = \lim_{s \to -\infty} p^0_{0s}, \quad p_\infty \begin{pmatrix} t \\ 1 \end{pmatrix} = \infty \quad \text{for all } t \in \mathbb{R},$$

and

$$p_{-\infty} = \lim_{s \to \infty} p^0_{0s}, \quad p_{-\infty} \begin{pmatrix} t \\ 1 \end{pmatrix} = -\infty \quad \text{for all } t \in \mathbb{R}.$$
A standard example of a circularly ordered space is the circle $\mathbb{T}$. An abstract circular (some authors prefer the name, cyclical) order $R$ on a set $X$ can be defined as a certain ternary relation. Intuitively, it is a linear (i.e., total) order which has been bent into a “circle”. For formal classical definitions and related new dynamical topics see [41, 44].

Let $(X,T)$ be a compact dynamical system. If $X$ is a circularly ordered (c-ordered) space, compact in its interval topology, and every $t$-translation $X \to X$ is circular ordered preserving (COP) then we say that $(X,T)$ is a circularly ordered system.

The class of linearly ordered dynamical systems (LOP) is defined similarly. Note that every linearly ordered compact $T$-system is a circularly ordered $T$-system. A prototypic example of a circularly ordered system is the circle $\mathbb{T}$ equipped with the action of the group $H_+\left(\mathbb{T}\right)$ (or, some of its subgroup) on $\mathbb{T}$. Several important Sturmian like symbolic dynamical systems are circularly ordered dynamical systems, hence tame. This is so because every circularly ordered system is tame. See the details in [41].

Let $X,Y$ be linearly (circularly) ordered sets. Below we denote by $M_+^{\text{c}}(X,Y)$ the set of linear (circular) order preserving maps from $X$ into $Y$. Similarly, by $H_+^{\text{c}}(X)$ we denote the group of all LOP (resp., COP) homeomorphisms $X \to X$. When $X$ is compact, $H_+^{\text{c}}(X)$ is a topological group carrying the usual compact open topology.

Our results show that there are naturally defined circularly ordered tame systems of all three types. Moreover, the (pointwise compact) space $M_+^{\text{c}}(X,Y)$ is first countable for every compact metrizable linearly ordered spaces $X,Y$ (Theorem 8.7). This result is a generalized version of the Helly theorem (for $X=Y=[0,1]$).

This fact implies that every linearly ordered metric dynamical $T$-system is tame (Theorem 8.8). In contrast, the circular version of the Helly space $M_+^{\text{c}}(\mathbb{T},\mathbb{T})$ is not first countable (Remark 8.11). This result demonstrates once more the relative complexity of circular orders when compared with linear orders.

**Orderable enveloping semigroups and the Tame$_2$ class**

By [53] in linearly ordered topological spaces (LOTS) the separability is hereditary. That is, in a separable LOTS every topological subspace is separable. This can be
easily extended to the case of c-ordered spaces, using the covering space, \[41\] (which is linearly ordered).

**Lemma 8.1.** Let \( R \) be a circular order on \( X \) such that \( X \) in its interval topology is separable. Then every topological subspace of \( X \) is separable.

**Proof.** By \[41\], Prop. 2.10] for every \( c \in X \) there exists a LOTS \( X(c) := ([c^-, c^+], \leq_c) \) such that \( X(c) \) we get from \( X \) splitting the point \( z \) into two new points \( z^-, z^+ \). The natural projection \( q: [c^-, c^+] \to X \) (identifying the endpoints of \( X(c) \)) is a c-order preserving quotient map. Here, the linear order \( \leq_c \) on \( X(c) \) is defined by
\[
\forall a \neq b \neq z \neq a,
\]
where \([z, a, b]\) indicates the fact that \((z, a, b) \in R\) (the triple is positively oriented).

Moreover, it is easy to see that the restriction of \( q \) on every interval \([a, b]_c \) is an isomorphism of linearly ordered sets, where \( c^- \neq a \) or \( c^+ \neq b \). The topologies on \( X \) and \( X(c) \) are both interval topologies. It follows that if \( D \) is a topologically dense subset of \( X \) then the same set \( D \) is dense in \([c^-, c^+]\). Hence, if the c-ordered space \( X \) is separable then the LOTS \( X(c) \) is also separable. Since \( X(c) \) is hereditarily separable and \( q: [c^-, c^+] \to X \) is continuous onto, we obtain that \( X \) is also hereditarily separable. \( \square \)

In particular, if the enveloping semigroup is c-ordered then its separability is hereditary. In view of our Definition \[0.2\] this leads to the following sufficient condition.

**Theorem 8.2.** If the enveloping semigroup \( E(X) \), as a compact space, is circularly ordered then the original metrizable dynamical system \( X \) is tame_2.

**Corollary 8.3.** The Sturmian like cascades \( \text{Split}(T, R; A; \alpha) \) are tame_2 (but not HNS).

**Proof.** We can apply Theorem \[8.2\] because for these systems the enveloping semigroup \( E \) becomes (by \[41\], Cor. 6.5]) a circularly ordered cascade, where \( E = T_\pi \cup \mathbb{Z} \) is a c-ordered compact (nonmetrizable) subset of the c-ordered lexicographic order \( \mathbb{T} \times \{-, 0, +\} \).

**Question 8.4.** For which c-ordered systems the enveloping semigroup is c-ordered (at least as a compact space)?

**Generalized Helly theorem and Tame_1 class**

It is a well known fact in classical analysis that every order preserving bounded real valued function \( f: X \to \mathbb{R} \) on an interval \( X \subseteq \mathbb{R} \) has one-sided limits. This can be extended to the case of linear order preserving functions \( f: X \to Y \) such that \( X \) is first countable and \( Y \) is sequentially compact; see \[25\]. The following lemma is easy to verify.

**Lemma 8.5.** Let \( p: X \to Y \) be LOP where \( X \) and \( Y \) are separable metrizable LOTS (linearly ordered topological spaces) and \( Y \) is compact. Then

1. \( p \) has one-sided limits \( p(a^-), p(a^+) \) at any \( a \in X \) and \( p(a) \in [p(a^-), p(a^+)] \).
2. \( p \) is continuous at \( a \) if and only if \( p(a^-) = p(a^+) \) if and only if \( p(a^-) = p(a^+) = p(a) \).
3. \( p \) has at most countably many discontinuity points.
Let \((X, \leq)\) be a linearly ordered set. Let us say that \(u \in X\) is a \textit{singular point} and write \(u \in \text{sing}(X)\), if there is a maximal element below \(u\) or a minimal element above it. It is equivalent to saying that for every \(v \neq u\), either \([u, v]\) or \((v, u]\) is a clopen set. 

**Lemma 8.6.** Let \((X, \leq)\) be a linearly ordered compact metric space. Then \(\text{sing}(X, \leq)\) is at most countable.

**Proof.** For every \(u \in \text{sing}(X)\) choose exactly one clopen (nonempty) set \([u, v)\) or \((v, u]\), where \(v \neq u\). This assignment defines a 1-1 map from \(\text{sing}(X)\) into the set \(\text{clop}(X)\) of all clopen subsets of \(X\). Now observe that \(\text{clop}(X)\) is countable for every compact metric space (take a countable basis \(\mathcal{B}\) of open subsets; then every clopen subset is a finite union of some members of \(\mathcal{B}\)). \(\square\)

Recall that the Helly space \(M_{+}([0, 1], [0, 1])\) is first countable (see for example, [39], page 127). The following theorem was inspired by this classical fact.

**Theorem 8.7** (Generalized Helly space). Let \(X\) and \(Y\) be linearly ordered sets with their interval topologies such that \(X\) and \(Y\) are compact metric spaces. Then the (compact) set \(M_{+}(X, Y)\) of all LOP maps is first countable in the pointwise topology.

**Proof.** Let \(p \in M_{+}(X, Y)\). Lemma 8.5 guarantees that \(p\) has at most countably many discontinuities. Denote this set by \(\text{disc}(p)\). Since \(X\) is compact and metrizable, there exists a countable dense subset \(A\) in \(X\). By Lemma 8.6 the set \(\text{sing}(X)\) is countable. Consider the following countable set

\[ C := \text{disc}(p) \cup \text{sing}(X) \cup A. \]

It is enough to show that \(C\) satisfies the condition of Lemma 1.2 with \(E := M_{+}(X, Y)\). So, let \(q \in M_{+}(X, Y)\) be such that \(q(c) = p(c)\) \(\forall x \in C\). We have to show that \(q(c) = p(c)\) \(\forall x \in X\).

Assuming the contrary, let \(q(x_0) \neq p(x_0)\) for some \(x_0 \in X\). Then, clearly, \(x_0 \in \text{cont}(p)\). Choose \(y_1, y_2 \in Y\) such that \(p(x_0) \in (y_1, y_2)\) and

\[ q(x_0) \notin (y_1, y_2). \]

There exists an open neighborhood \(O\) of \(x_0\) in \(X\) such that \(p(O) \subset (y_1, y_2)\). Since open intervals form a topological basis of the topology of a circular order, we can suppose that \(O\) is an open interval \((x_1, x_2)\) containing \(x_0\). By our choice, \(x_0\) is not singular. Therefore, \((x_1, x_0)\) and \((x_0, x_2)\) are nonempty. Since \(A\) is dense in \(X\), there exist \(a_1, a_2 \in A\) such that \(a_1 \in (x_1, x_0)\) and \(a_2 \in (x_0, x_2)\). Then \(a_1 < x_0 < a_2\). So, \(q(a_1) \leq q(x_0) \leq q(a_2)\). Since \(q(a_1) = p(a_1), q(a_2) = p(a_2)\) and \(p(a_1), p(a_2) \in (y_1, y_2)\) it follows that \(y_1 < q(x_0) < y_2\). We get

\[ q(x_0) \in (y_1, y_2). \]

This contradiction completes the proof. \(\square\)

**Theorem 8.8.** Every linearly ordered compact metric dynamical system is tame_{1}.

**Proof.** Let \(X\) be a compact metrizable linearly ordered dynamical system. Every element \(p \in E(X)\) is a LOP selfmap \(X \to X\), because \(M_{+}(X, X)\) is pointwise closed. So, \(E\) is a subspace of \(M_{+}(X, X)\) which is first countable by Theorem 8.7. \(\square\)
Example 8.9. Consider the linearly ordered system \(([0, 1], H_+([0, 1]))\). The enveloping semigroup of this c-order preserving system is a (compact) subspace of the Helly space which is first countable. So, this system is tame_1. It is not tame_2. In fact, it is (like the Helly space) not hereditarily separable. There exists a discrete uncountable subspace in the enveloping semigroup. For each \(z \in [0, 1]\) consider the functions

\[
f_z : [0, 1] \to [0, 1], \quad f_z = \begin{cases} 
0 & \text{for } x < z \\
\frac{1}{2} & \text{for } x = z \\
0 & \text{for } x > z.
\end{cases}
\]

Then \(\{f_z : z \in (0, 1)\}\) is an uncountable discrete subset of \(E(X)\).

Recall again that every separable linearly

Circularly ordered systems, in general, are not tame_1

Proposition 8.10. Let \(H_+(T)\) be the Polish topological group of all c-order preserving homeomorphisms of the circle \(T\). The minimal circularly ordered dynamical system \((T, H_+(T))\) is tame but not tame_1.

Proof. This system is tame being a circularly ordered system, [41]. Let us show that the enveloping semigroup of this c-order preserving system is not first countable. Choose any point \(a \in T\). For every \(b \neq a\) in \(T\) the pair \((a, b)\) is the target pair of a loxodromic idempotent \(p = p_{(a,b)}\) with attracting point \(a\) and a repulsing point \(b\).

![Figure 3. loxodromic idempotent p](image)

Then, according to Proposition 6.1.2, the parabolic idempotent \(p_a\) defined by \(p_a x = a, \forall x \in T\), does not admit a countable basis for its topology. This example, in particular, shows that a null system need not be tame_1. \(\square\)

Remark 8.11. Theorems 8.7 and 8.8 cannot be extended, in general, to circular orders. Indeed, the “circular analog of Helly’s space” \(M_+(T, T)\) (which is a separable Rosenthal compactum) is not first countable. Also its subspace, the enveloping semigroup \(E(T)\) of the circularly ordered system \((T, H_+(T))\) from Example 8.10 is not first countable.

Remark 8.12. Let \(Q_0 = Q/\mathbb{Z} \subset T\) be the circled rationals with the discrete topology and \(G = Aut(Q_0)\) the automorphism group (in its pointwise topology) of the circularly ordered set \(Q_0\). In [44] we have shown that the universal minimal \(G\)-system of the Polish topological group \(G\) can be identified with the circularly ordered compact metric space \(\text{Split}(T; Q_0)\), which is constructed by splitting the points of \(Q_0\) in \(T\). In
a similar way to the proof of Proposition 8.10 one shows that the $G$-system $M(G)$ is tame but not tame$_1$.

In view of Examples 5.7, 5.8, Lemmas 7.3 and 7.6 and the examples in the present section, we pose the following.

**Question** 8.13. Let $(X,T)$ be a metric, point transitive, tame system which is not tame$_1$. Is there always an extension $\pi: (X^*,Y) \to (X,T)$ such that $(X^*,T)$ is metric, point transitive and tame$_1$? Is there such an extension $\pi$ which is also at most two-to-one?

It is though worth mentioning that all of these examples are connected to ordered structures, which may be the secrete behind the existence of the tame$_1$ extension.

9. **Minimal left ideals**

According to Ellis’ theory every enveloping semigroups $E(X,T)$ of a dynamical system $(X,T)$ contains at least one minimal left ideal. These minimal left ideals are the same as the minimal subsets of the dynamical system $(E(X,T),T)$. A minimal left ideal $M$ has the following form: The set $J$ of idempotents in $M$ is nonempty. We choose an arbitrary idempotent $u \in J$ and set $G = uM$. Then $G$ is a group, $M = J : G = \bigcup_{v \in J} vG$, and the representation of an element $p \in M$ as $p = v\alpha$, with $v \in J$ and $\alpha \in G$ is unique. For each $\alpha \in G$, the map $R_\alpha: p \mapsto p\alpha$ is a homeomorphism of $M$ onto itself which commutes with the (left) action of $T$ on $M$, so that $R_\alpha$ is an automorphism of the dynamical system $(M,T)$. Moreover, the map $\alpha \mapsto R_\alpha$ is a group isomorphism between $G$ and $\text{Aut}(M,T)$.

A minimal system $(X,T)$ admits a single left minimal ideal if and only if the proximal relation $P \subset X \times X$ is an equivalence relation, but in general even a minimal metrizable system can admit $2^c$ minimal left ideals (see [34]). It may happen that the proximal relation $P$ on a minimal system $(X,T)$ is an equivalence relation but is not closed (see [59]). The relation $P$ is closed if and only if $E(X,T)$ has a unique minimal ideal $M$ and $J$ is a closed subset of $M$.

Recall that a metric minimal tame dynamical system $(X,T)$ which admits an invariant measure is almost automorphic [33], and in particular its proximal relation is a closed equivalence relation. Thus the enveloping semigroup of such a system always admits a unique minimal left ideal $M$ and its subset of idempotents $J$ is a closed subset of $M$. In fact, in many such systems it may happen that this unique minimal left ideal coincides with the adherence semigroup $A(X,T)$.

Let $(X,T)$ be a metric minimal tame system admitting a $T$-invariant probability measure. Then the system $(X,T)$ is almost automorphic and the extension $\pi: X \to Y$, where $Y$ is the largest equicontinuous factor of $X$, is an almost one-to-one map. Let, as before

$$X_0 = \{x \in X : \pi^{-1}(\pi(x)) = \{x\}\}, \quad Y_0 = \pi(X_0) = \{y \in Y : |\pi^{-1}(y)| = 1\}.$$

**Proposition 9.1.** Let $(X,T)$ be a metric minimal tame system admitting a $T$-invariant probability measure. Then the enveloping semigroup $E(X,T)$ contains a unique minimal left ideal $M \subset E(X,T)$, and the space $M$ is a separable Rosenthal compactum. If $Y \setminus Y_0$ is countable, i.e. when $(X,T)$ is $AA_c$, then $M$ is first countable.
Proof. It is shown in [30] that the minimal system \((X, T)\) is almost automorphic; i.e. it is an almost one-to-one extension of its largest equicontinuous factor \((Y, T)\). It then follows that the proximal relation on \(X\) is a closed equivalence relation and thus \(E(X, T)\) admits a unique minimal left ideal \(M\) and its set of idempotents \(J\) is closed. Being a closed subset of a Rosenthal compactum \(M\) is also a Rosenthal compactum. Each \(T\)-orbit in \(M\) is dense and thus \(M\) is separable.

The dynamical system \((Y, T)\) is minimal and equicontinuous and therefore has the form \(Y = K/L\) where \(K\) is a compact second countable topological group and \(L \leq K\) is a closed subgroup. The enveloping semigroup of the system \((Y, T) = (K/L, T)\) is the system \((K, T)\) and it follows that there is a homomorphism

\[ \tilde{\pi}: (M, T) \to (K, T), \]

which is a proximal extension. It also follows that the restriction of \(\tilde{\pi}\) to \(G\) is a group isomorphism \(\tilde{\pi} \upharpoonright G: G \to K\).

We also have \(\tilde{\pi}^{-1}(e) = J\), where \(e\) is the identity element of \(K\) and it follows that \(J\) is a closed \(G_\delta\) subset of \(M\).

We observe that it suffices to show that each \(v \in J\) is a \(G_\delta\) point of \(J\). In fact, as \(\{R_\alpha : \alpha \in G\} \cong \text{Aut} (M, T)\) it will follow that every \(p = v\alpha \in vG\) is also a \(G_\delta\) point of \(M\).

Now it follows from our assumption the \(Y \setminus Y_0\) is countable that in fact \(J\) is metrizable. For each \(y \in Y \setminus Y_0\) we choose a point \(x_y \in \pi^{-1}(y)\) and define the evaluation map

\[ \text{ev}_y: v \mapsto vx_y, \quad J \to \pi^{-1}(y). \]

Now the countable collection of continuous maps \(\{\text{ev}_y\}_{y \in Y \setminus Y_0}\) separates points on \(J\) and our claim follows. This completes the proof of the proposition.

\[ \square \]

Remark 9.2. If in the above proposition we replace the condition that \(Y \setminus Y_0\) be countable by the assumption that the set \(J\) of minimal idempotents is metrizable, we obtain the same result.

Example 9.3.

1. In the case of a hyperbolic group acting on its Gromov boundary the unique minimal ideal is isomorphic to the action on the boundary, hence actually metrizable (see Corollary 6.6).

2. The Sturmian system is an example where Adh \((X, T)\) is minimal and hence it coincides with the unique minimal left ideal. Topologically it is the split circle (see [37, Example 14.10]). In this example \(|J| = 2\).

3. For any system which satisfies the assumptions of Theorem 3.1 we have that Adh \((X, T)\) is minimal and hence coincides with the unique minimal left ideal.

4. For the Floyd system \((X, T)\) we have

\[ E(X, T) \supseteq \text{Adh} (X, T) \supseteq M, \]

where \(M\) is the unique minimal left ideal in \(E(X, T)\) (see [47]).

5. In the example [42, Example 8.43] we see that Adh \((X, T) = E(X, T) \setminus \mathbb{Z} = M\) is the unique minimal left ideal of \(E(X, T)\). Algebraically it is the product set \(\mathbb{T}^d \times \mathcal{F}\), where \(\mathcal{F}\) is the collection of ordered orthonormal bases for \(\mathbb{R}^d\).
It is easy to see that $J = \mathcal{F}$ and that the topology induced on $J$ is actually the natural compact metric topology on $\mathcal{F}$. Thus, by Remark 9.2, the system $(X, T)$ is tame. Note that this AA system is not $\text{AA}_c$.

10. Are the groups $vG$, $v \in J$ always homeomorphic to each other?

For the Sturmian system $(X, T)$ (or any other system of the form $\text{Split}(T, R_\alpha; A)$), the Adherence semigroup $\text{Adh}(X, T)$ is the Ellis’ two circles system and it coincides with the unique minimal left ideal $M$ of $\mathcal{E}(X, T)$. The set $J$ of minimal idempotents in $M$ consists of two elements

$$J = \{u_+, u_-\}.$$

If we choose $u_+ = u$ then the group $G = uM$ is algebraically isomorphic to the circle group $\mathbb{T}$, and as a topological space it is homeomorphic to the Sorgenfrey circle. The map $g \mapsto -u_- g$ is a topological isomorphism from $G$ onto $u_-G$.

We next consider a similar but more complicated example where the same phenomenon holds (compare with Subsection 3.1).

**Example 10.1.** Let $\alpha \in (0, 1)$ be an irrational number. We start our construction with the dynamical system $(\mathbb{T}, R_\alpha)$ defined on the circle $\mathbb{T} = \mathbb{R}/\mathbb{Z}$ by $R_\alpha \theta = \theta + \alpha \pmod{1}$. Let

$$F(\theta) = \begin{cases} 
\cos\left(\frac{2\pi \theta}{\alpha}\right) & 0 < \theta < 1/2 \\
2\theta & 1/2 \leq \theta < 1 \\
0 & \theta = 0
\end{cases}$$

a function on $\mathbb{T}$ with 0 as the unique discontinuity point. Set $f(n) = F(n\alpha)$, a function in $\Omega = [-1, 2]^\mathbb{Z}$. Let $x_0 \in \mathbb{T} \times [-1, 2]^\mathbb{Z}$ be defined by

$$x_0(n) = (0, F(n\alpha)) = (0, f(n)), \quad n \in \mathbb{Z}.$$ 

Let $T: \mathbb{T} \times \Omega \to \mathbb{T} \times \Omega$ be defined by

$$T(\theta, \omega) = (\theta + \alpha, S\omega),$$

where for $\omega \in \Omega$ the shift homeomorphism $S: \Omega \to \Omega$ is defined by $S\omega(n) = \omega(n + 1)$. Let

$$X = \text{cls} \, \mathcal{O}_T(x_0) = \{T^n x_0 : n \in \mathbb{Z}\} \subset \mathbb{T} \times \Omega.$$
We let \( \pi : X \to \mathbb{T} \) denote the projection on the \( \mathbb{T} \) coordinate. Clearly \( \pi : (X,T) \to (\mathbb{T}, R_\alpha) \) is a homomorphism of dynamical systems. One can also easily see that \( \pi \) is an almost one-to-one extension, with \( \pi^{-1}(\pi(x)) = \{x\} \) for every \( x \in X \) such that \( \pi(x) \notin O_{R_\alpha}(0) \). In fact for a sequence \( n_i \) such that \( \lim n_i \alpha = \theta \notin O_{R_\alpha}(0) \), we have:

\[
\lim_{i \to \infty} T^{n_i}x_0 = x, \quad \text{with} \quad x(n) = (\theta, F(\theta + n\alpha)), \quad (n \in \mathbb{Z}).
\]

It then follows that the system \((X,T)\) is minimal and almost automorphic. Let \( n_i \in \mathbb{Z} \) be a sequence such that \( n_i \alpha \to 0 \) with \( n_i \alpha \in [1/2, 1) \). Assume that \( x_2 := \lim T^{n_i}x_0 \) exists. It is then easy to see that \( x_2 \) has the form

\[
x_2(n) = \begin{cases} (0, f(n)) & n \neq 0 \\ (0, 2) & n = 0. \end{cases}
\]

On the other hand if \( n_i \in \mathbb{Z} \) is a sequence such that \( n_i \alpha \to 0 \) with \( n_i \alpha \in (0, 1/2) \) and such that \( x_t := \lim T^{n_i}x_0 \) exists, then \( x_t \) has the form

\[
x_t(n) = \begin{cases} (0, f(n)) & n \neq 0 \\ (0, t) & n = 0, \end{cases}
\]

for a unique \( t \in [-1, 1] \).

This gives us a full description of the fiber over \( 0 \):

\[
\pi^{-1}(0) = \{x_2\} \cup \{x_t : t \in [-1, 1]\}.
\]

Of course this defines also \( \pi^{-1}(n\alpha) \) for every \( n \in \mathbb{Z} \) and, as \( \pi^{-1}(\theta) \) is a singleton for every \( \theta \) which is not in the \( R_\alpha \)-orbit of 0, we now have a complete description of all the points of \( X \).

As a base for the topology at \( x_2 \) we can take the collection \( \{V_k(x_2) : k = 2, 3, \ldots\} \), where

\[
V_k(x_2) = \pi^{-1}(1 - 1/k, 1) \cup \{x_2\}.
\]

The collection \( \{V_{k,l}(x_t) : k, l = 2, 3, \ldots\} \), where

\[
V_{k,l}(x_t) = (\pi^{-1}(0, 1/k) \cap \{x : x(0) = (\pi(x), s) & |s-t| < 1/l\}) \cup \{x_s : |t-s| < 1/l\},
\]

will serve as a basis for the topology at \( x_t \) \( (0 \leq t \leq 1) \).

Of course we have \( T^nx_k(x_2) = V_k(T^nx_2) \) and \( T^nx_k(x_t) = V_k(T^nx_t) \), for \( n \in \mathbb{Z} \). Finally for a point \( x \notin \pi^{-1}(O_{R_\alpha}(0)) \) the collection \( \{V_k(x), k = 2, 3, \ldots\} \), where

\[
V_k(x) = \pi^{-1}(\pi(x) - 1/k, \pi(x) + 1/k),
\]

is a basis for the topology at \( x \).

Next note that, as the elements of \( \pi^{-1}(0) \) differ from each other only at one coordinate, the extension \( \pi \) is asymptotic. It then follows that our system \((X,T)\) is tame and that \( E(X,T) \) is first countable (see Theorem 3.11). Thus we proved the following:

**Claim 10.2.** The system \((X,T)\) is \( \text{AA}_c \) (but not \( \text{AA}_{cc} \)) and it is tame_1.

We will next determine the nature of the elements of the adherence semigroup \( \text{Adh}(X,T) = E(X,T) \setminus \{T^n : n \in \mathbb{Z}\} \).

We start by determining the idempotents in \( \text{Adh}(X,T) \). If \( v = v^2 \) is such an idempotent, then clearly \( \pi_* (v) = \text{Id}_X = 0 \), where \( \pi_* : E(X,T) \to E(\mathbb{T}, R_\alpha) \cong \mathbb{T} \) is the canonical homomorphism induced by \( \pi \), and where \( E(\mathbb{T}, R_\alpha) \) is identified with \( \mathbb{T} \).
Now if $T_{n_1}^i \to v$, then it follows that $n_i \alpha = 0$, and thus $T_{n_1}^i x_0 \to vx_0 = x$, with either $\epsilon = 2$ or $\epsilon = t \in [-1, 1]$. We now note that this determines $v$, since then $vx = x$ when $x \not\in O_T(x_0)$ and $vT_{j}^i x = T_{j}^i vx = T_{j}^i x$, for every $x \in \pi^{-1}(0)$ and $j \in \mathbb{Z}$. We then write $v = v_\epsilon$. Conversely if $n_i$ is a sequence in $\mathbb{Z}$ such that $n_i \alpha = 0$ and $T_{n_i}^i x_0 \to x$, then we must have $T_{n_i}^i \to v_\epsilon$ in $E(X,T)$. Note that clearly $v_\epsilon$ is a minimal idempotent.

Let now $p = \lim T_{n_j}^i$ be an element of Adh $(X,T)$, with $\lim n_i \alpha = \gamma \in \mathbb{T}$. For $x \in \pi^{-1}(-\gamma)$ we have $px = x_\epsilon$ for some $\epsilon$ and it follows that $p(\pi^{-1}(-\gamma)) = \{x_\epsilon\}$. We now check and see that $v_\epsilon p = p$. It follows immediately that Adh $(X,T) = M$, the unique minimal left ideal of $E(X,T)$. Denote by $J$ the set of minimal idempotents in Adh $(X,T)$; thus

$$J = \{v_\epsilon \cup \{v_t : t \in [-1, 1]\}.$$

Note that $v, v_\eta = v_\epsilon$ for every $\epsilon$ and $\eta$. For convenience let $v = v_2$ and we set $G = uM$. With this notation we have that for $p$ as above, $p = v_\epsilon p$ and denoting $g_\gamma = up \in G$, we get $p = v_\epsilon g_\gamma$. Thus

$$G = uM = \{g_\gamma : \gamma \in \mathbb{T}\} \cong \mathbb{T},$$

and every $p \in M$ has uniquely the form $p = v_\epsilon g_\gamma$ with $g_\gamma \in G$ and $v_\epsilon \in J$.

Given $p \in \text{Adh} (X,T)$ with $\pi_+(p) = \gamma$, in order to determine the unique $\epsilon$ for which $v_\epsilon p = p \in v_\epsilon G$, we have to evaluate $px(0) = (0, \epsilon)$ for some (any) $x \in \pi^{-1}(-\gamma)$.

The collection $G$ is actually a group which algebraically is isomorphic to $\mathbb{T}$, with $g_\gamma \leftrightarrow \gamma$, and the map $r_\gamma : p \mapsto pg_\gamma$ defines a (continuous) automorphism of the minimal system $(M,T) = (\text{Adh} (X,T), T)$. Thus $G \cong \text{Aut} (\text{Adh} (X,T), T) = \{r_\gamma : \gamma \in \mathbb{T}\}$.

As the topology of $A(X,T)$ is the topology of pointwise convergence, it is now easy to see that the topology induced on $J$ is such that $u = u_2$ is an isolated point of $J$ and that the collection $\{v_t : t \in [-1, 1]\}$ is naturally homeomorphic to the interval $[-1, 1]$.

For $x \in X$ let $\text{eva}_x : \text{Adh} (X,T) \to X$ denote the evaluation map defined by $\text{eva}_x(p) = px, \quad (p \in \text{Adh} (X,T))$. Clearly the collection of sets

$$\{\text{eva}_x^{-1}(V) : x \in X, \ V \text{ open in } X\},$$

forms a sub-base for the topology of Adh $(X,T)$.

We will next show that $G$, with the topology it inherits from Adh $(X,T)$, is homeomorphic to the Sorgenfrey circle (i.e. the half open intervals topology on $\mathbb{T}$).

We now have that when $x$ ranges over $X$, and we write $\pi(x) = -\theta$, sets of the form:

$$G \cap \text{eva}_x^{-1}(V_k(x_2)) = \{g_\gamma : \gamma - \theta \in (1 - 1/k, 1)\} \cup \{g_\theta\} \cong (\theta - 1/k, \theta],$$

$$G \cap \text{eva}_x^{-1}(V_k,l(x)) = \{g_\gamma : \gamma - \theta \in (0, 1/k)\} \cong (\theta, \theta + 1/k),$$

and for $x' \not\in \pi^{-1}(O_{R_\alpha})$ with $\pi(x') = \theta'$

$$G \cap \text{eva}_x^{-1}(V_k(x')) = \{g_\gamma : \gamma - \theta \in (\theta' - 1/k, \theta' + 1/k) \cong (\theta' + \theta - 1/k, \theta' + \theta + 1/k),$$

$$k, l = 2, 3, \ldots, t \in [-1, 1],$$
together with all their $T^n$-translates, form a basis for the topology of $G$. This completes the proof of the claim that the relative topology on $G$ is the left-half-open interval Sorgenfrey topology on $\mathbb{T}$.

Similarly we see that for each $t \in [-1, 1]$ the topology induced on the group $v_tG$ is the right-half-open interval Sorgenfrey topology on $\mathbb{T}$.

Thus for $t, s \in [-1, 1]$ the map 

$$L_{v_t}: v_sG \rightarrow v_tG, \quad v_s g \gamma \mapsto v_t g \gamma$$

is a topological isomorphism, while for $u$ and $t$ the map 

$$L_u: v_tG \rightarrow G, \quad v_t g \gamma \mapsto -g$$

is a topological isomorphism.

**Question 10.3.** Is there a minimal dynamical system $(X, T)$ such that in $E(X, T)$ there is a minimal left ideal $M$ and two idempotents $u, v \in M$ such that the groups $uM$ and $vM$ (with the induced topology from $M$) are not homeomorphic?

### 11. The $\beta$-Rank of a Tame System

Let $(X, T)$ be a metric (tame) dynamical system, $E = E(X, T)$ its enveloping semigroup. For $p \in E$ define the the oscillation function of $p$ at $x \in X$ as 

$$\text{osc} \,(p, x) = \inf \{ \sup_{x_1, x_2 \in V} d(px_1, px_2) : V \subset X \text{ open}, x \in V \}$$

and similarly, for $A$ a subset of $X$ with $x \in A$,

$$\text{osc} \,(p, x, A) = \text{osc} \,(p \upharpoonright A, x).$$

Consider, for each $\epsilon > 0$, the derivative operation 

$$A \mapsto A'_{\epsilon, p} = \{ x \in A : \text{osc} \,(p, x, A) \geq \epsilon \}$$

and by iterating define $A^{\alpha}_{\epsilon, p}$ for $\alpha < \omega_1$. Let 

$$\beta(p, \epsilon, A) = \begin{cases} \text{least } \alpha \text{ with } A^{\alpha}_{\epsilon, p} = \emptyset, & \text{if such an } \alpha \text{ exists} \\ \omega_1, & \text{otherwise}, \end{cases}$$

Set $\beta(p, \epsilon) = \beta(p, \epsilon, X)$ and define the oscillation rank $\beta(p)$ of $p$ by 

$$\beta(p) = \sup_{\epsilon > 0} \beta(p, \epsilon).$$

Note that $p$ is continuous iff $\beta(p) = 1$.

Finally define the $\beta$-rank of the system $(X, T)$ as the ordinal 

$$\beta(X, T) = \sup \{ \beta(p) : p \in E \}.$$ 

The following claim follows from [12], and [51, Theorem 3, Theorem 8] (where the $\alpha, \beta$ and $\gamma$ ranks are shown to be essentially equivalent for bounded Baire class 1 functions).

**Claim 11.1.** For a metric tame dynamical system $(X, T)$ we have $\beta(X, T) < \omega_1$.

**Claim 11.2.** For the Sturmian system we have $\beta(X, T) = 2$. 

Proof. In order to compute $\beta(u_+)$ we observe that for a fixed $\epsilon > 0$ there are only finitely many points, all of the form $x = T^n x_0^-$, where osc $(u_+, x) \geq \epsilon$. Thus $\beta(u_+\epsilon) = 2$ for every $\epsilon > 0$, hence $\beta(u_+) = 2$. Similarly $\beta(u_-) = 2$ and, as we have seen, the $\beta(\omega)$-rank 2 (as Baire class 1 functions), and, as we have seen, the $\beta$-rank of these dynamical systems is 2. We will show next that for some separating cover $A_0, A_1$ of the circle by two closed sets (so that again the $\beta$ rank of the function $1_{A_0}$ is 2), the corresponding almost automorphic system $(X, T)$ is not even tame, so that $\beta(X, T) = \omega_1$.

The following propositions and theorem are proved in [26, Proposition 3.5, Proposition 3.6, Corollary 3.7].

Proposition 11.5. Let $(\mathbb{T}, R_\alpha)$ be the rotation system with $\alpha$ irrational and let $B \subset \mathbb{T}$ be a residual subset. Let $A_0, A_1 \subset \mathbb{T}$ be two closed subsets that satisfy

1. $\text{cls int } (A_0) = A_0$ and $\text{cls int } (A_1) = A_1$.
2. $\text{int } (A_0) \cap \text{int } (A_1) = \emptyset$.
3. $C = \partial A_0 = \partial A_1$ is a Cantor set.

Then there exists an infinite subset $I \subset \mathbb{Z}$ such that for every $a \in \{0, 1\}^I$, there is a point $x \in B$ with $T^ix = x + i\alpha \in \text{int } (A_{a(i)})$ for every $i \in I$.

Now let $F = 1_{A_1}$, i.e.

$$F(\theta) = \begin{cases} 1, & \theta \in A_1, \\ 0, & \text{otherwise}. \end{cases}$$

Choose a point $y_0 \in \text{int } A_1$ and let $x_0 = f \in \{0, 1\}^\mathbb{Z}$ be defined by $x_0(n) = f(n) = F(y_0 + n\alpha)$, $(n \in \mathbb{Z})$. We set $X = \text{cls } \{T^n x_0 : n \in \mathbb{Z}\}$, where $T$ is the shift map on $\{0, 1\}^\mathbb{Z}$.

The dynamical system $(X, T)$ is almost automorphic with a maximal equicontinuous factor $(\mathbb{T}, R_\alpha)$, where the factor map $\pi : (X, T) \to (\mathbb{T}, R_\alpha)$ is an almost one-to-one extension and, in particular, $\pi^{-1}(y_0) = \{x_0\}$. It is also a cut and project system as follows (see [56], [9]):

Proposition 11.6. The almost automorphic subshift $(X, T)$ is isomorphic to the cut and project dynamical system $(\Omega(\lambda(W)), \mathbb{Z})$ obtained from the cut and project scheme $(\mathbb{Z}, \mathbb{T}, L)$, with lattice $L = \{(n, n\alpha) : n \in \mathbb{Z}\} \subset \mathbb{Z} \times \mathbb{T}$, where
A HIERARCHY IN THE CLASS OF TAME DYNAMICAL SYSTEMS

• $0 \in \mathbb{T}$ has a unique preimage under the factor map $\beta: (\Omega(\lambda(W)), \mathbb{Z}) \rightarrow (\mathbb{T}, R_\alpha)$.
• $W = \beta([1])$, where $[1] = \{\xi \in \{0, 1\}^\mathbb{Z} : \xi(0) = 1\}$.

Moreover, the window $W$ is proper, that is, $\text{int}(W) = W$.

Now in this situation the following theorem applies.

**Theorem 11.7.** Suppose that $(\mathbb{Z}, \mathbb{T}, L)$ is a cut and project scheme. If $W$ is a proper window and $\partial W$ is a Cantor set, then the system $(\Omega(\lambda(W)), \mathbb{Z})$ admits an infinite free set $I \subset \mathbb{G}$. i.e. for every $a \in \{0, 1\}^I$, there is a point $x \in \Omega(\lambda(W))$ with $x(i) = a(i)$ for every $i \in I$. Thus the system $(\Omega(\lambda(W)), \mathbb{Z})$ is not tame.

**Question 11.8.** Is there, for every ordinal $\alpha < \omega_1$, a tame metric system $(X, T)$ with $\beta(X, T) = \alpha$? Or, to be more modest, find a dynamical system with $\beta(X, T) = 3$.

**12. More open questions**

A separable Banach space $V$ is Rosenthal if and only if its *enveloping semigroup* $\mathcal{E}(V)$ is a (separable) Rosenthal compactum (see the BFT dichotomy for Banach spaces [39, Theorem 5.22]).

Another characterization, due to Odell and Rosenthal is, that a separable Banach space $V$ is Rosenthal if and only if every element $x^{**} \in B^{**}$ is a Baire class 1 function on $B^*$, iff $B^{**}$ is a separable Rosenthal compactum. One can ask what is the nature of the spaces $B^{**}$ in terms of the Todorčević classes mentioned in Theorem 0.3.

Now, as noted by Bourgain [10] the point 0 is not a $G_\delta$ subset of $B^{**}$ for any Rosenthal space which is not Asplund. In particular, it follows that $B^{**}$ is not first countable (at 0). This implies that the enveloping semigroup $\mathcal{E}(V)$ of $V$ is not hereditarily separable (because, by [39, Lemma 2.6.2] the weak-star compact ball $B^{**}$ is a continuous image of $\mathcal{E}(V)$).

**Question 12.1.** Is there a separable Rosenthal Banach space $V$ such that $\mathcal{E}(V)$ is first countable but not metrizable (equivalently, $V$ is not Asplund)?

**Question 12.2.** Every continuous topological group action on a dendrite $D$ is tame, [43]. Is it always tame$_1$?

This is the case for the simplest nontrivial dendrite $D = [0, 1]$. This can be proved by a minor modification of the arguments in Example 8.9. Note that the circle $S^1$, which is a local dendrite, does admit an action of $\text{GL}(d, \mathbb{R})$ which is tame but not tame$_1$ (Example 5.7). See also Proposition 8.10.

For other questions in the present work see: Questions 1.5, 1.6, 5.6, 6.8, 8.4, 8.13, 10.3 and 11.8.
