Abstract

We investigate the shape of critical points for a free energy consisting of a nonlocal perimeter plus a nonlocal repulsive term. In particular, we prove that a volume-constrained critical point is necessarily a ball if its volume is sufficiently small with respect to its isodiametric ratio, thus extending a result previously known only for global minimizers.

We also show that, at least in one-dimension, there exist critical points with arbitrarily small volume and large isodiametric ratio. This example shows that a constraint on the diameter is, in general, necessary to establish the radial symmetry of the critical points.

Keywords: Ohta–Kawasaki functional, long-range interactions, symmetry results, critical points

Mathematics Subject Classification: 49Q10, 49Q20, 35B38, 58J70

1. Introduction

In recent years the following variational problem has been widely studied:

$$\min_{|E|=m} P(E) + \int_{E^2} \frac{dx
dy}{|x-y|}$$

(1)
where $P(E)$ denotes the perimeter of a set $E \subset \mathbb{R}^3$. Such problem first appeared in the liquid drop model of the atomic nuclei proposed by Gamow in 1928 [14] and then developed by other researchers [3, 9], and it is also relevant in some models of diblock copolymer melts [5, 18].

In [16, 17] (see also [6]) the authors showed that global minimizers of (1) exist if the volume $m$ is small, and do not exist if the volume is large enough. They also showed that minimizers are necessarily balls if the volume is small enough. This result has been later extended in [15] to connected critical points in two-dimensions. However it is still not known if there exist non-spherical critical points of (1) with arbitrarily small volume.

In this paper we consider the modified energy

$$
F(E) := P(E) + \int_{E \times E} \frac{dx \, dy}{|x - y|^{n+s}},
$$

with $s \in (0, 1)$ and $\alpha \in (0, n)$, which is a nonlocal extension of the energy in (1), which takes into account long-range interactions in the attractive term of surface tension type.

Here

$$
P(E) := \int_{E \times E} \frac{dx \, dy}{|x - y|^{n+s}}
$$

denotes the so-called fractional perimeter of $E$, recently introduced by Caffarelli, Roquejoffre and Savin in [4], where they initiated the analysis of the corresponding plateau problem (see e.g. [11] for motivations and a survey of recents on this topic and [13, 10] and the references therein for related isoperimetric problems).

The functional (2) has been studied in [12], where the authors showed that volume-constrained minimizers are balls, if the volume is small enough, thus extending the results in [16, 17].

We observe that, for any $\lambda > 0$, it holds

$$
F(\lambda E) = \lambda^{n-s} \left( P(E) + \lambda^{n-\alpha+s} \int_{E \times E} \frac{dx \, dy}{|x - y|^{n}} \right)
$$

Therefore, minimizing $F$ under the volume constraint $|E| = m$ is equivalent to minimize the functional

$$
F_{\varepsilon}(E) := P(E) + \varepsilon \int_{E \times E} \frac{dx \, dy}{|x - y|^{n}}
$$

under the constraint $|E| = 1$, with $\varepsilon := m^{1-\frac{n}{n+s}}$.

If $E$ is a critical point of $F_\varepsilon$ with boundary of class $C^2$, then

$$
\kappa_E(x) + c \varepsilon V_\varepsilon(x) = \lambda_c \quad \text{for any } x \in \partial E,
$$

for a suitable $\lambda_c \in \mathbb{R}$. Here above, $c > 0$ is a normalizing constant,

$$
V_\varepsilon(x) := \int_E \frac{dy}{|x - y|^{n}}
$$

is the potential, and $\kappa_E$ is the fractional mean curvature of $E$, i.e.

$$
\kappa_E(x) := \int_{E^c} \frac{\chi_{E^c}(y) - \chi_E(x)}{|x - y|^{n+s}} \, dy,
$$

where the integral is meant in the principal value sense, see e.g. [1, 4, 12] for further details on this notion of mean curvature.
Notice that, if $E$ is a critical point of $F$ with boundary of class $C^2$, by elliptic regularity (see [2]) the boundary of $E$ is in fact of class $C^\infty$.

The main result of this paper is that critical points of $F$ are necessarily spherically symmetric, if their volume is small enough with respect to their isodiametric ratio, which is defined as

$$I(E) := \frac{m^n}{\text{diam}(E)}.$$  

(6)

To state this result precisely, we introduce a scale parameter that links volume and diameter of a set, given by

$$\beta = \beta(n, \alpha, s) := \frac{n + s - \alpha}{(2n + s + 1)n}.$$  

(7)

With this notation, we have:

**Theorem 1.** Let $n \geq 2$, $s \in (0, 1)$ and $\alpha \in (0, n - 1)$.

There exists $c_o = c_o(n, \alpha, s) > 0$ such that, if $E_*$ is a bounded, volume-constrained, critical point of $F$ with smooth boundary, such that

$$|E_*|^\beta \leq c_o I(E_*),$$  

(8)

then $E_*$ is a ball.

Equivalently, if $E$ is a bounded, volume-constrained, critical point of $F$ with smooth boundary, such that

$$|E| = 1 \quad \text{and} \quad \text{diam}(E) \leq c_o e^{-\frac{1}{2n + s + 1}},$$  

(9)

then $E$ is a ball.

We think that it is an interesting open problem to investigate the case $\alpha \in [n - 1, n)$ in theorem 1 (in our approach the hypothesis $\alpha \in (0, n - 1)$ provides an integrability condition in the forthcoming lemma 3).

We observe that condition (8) does not violate the isodiametric inequality, since the right hand side is scale invariant, and so it is not void for small sets. Moreover, we remark that in problems like the ones considered in this paper, in which an aggregating energy is competing with a repulsive one, universal bounds on the diameter of the solutions do not hold in general. Indeed, roughly speaking, the repulsive term of the energy functional may produce critical points with disconnected components which lie ‘far away’ one from the other and which therefore violate uniform diameter bounds. To give a concrete example of this phenomenon we provide the following result:

**Theorem 2.** Let $n = 1$, $s \in (0, 1)$ and $\alpha \in (0, 1)$.

There exists $\bar{m} = \bar{m}(\alpha, s) > 0$ such that, if $m \in (0, \bar{m})$, there exists a bounded critical point $E_*$ of $F$ with volume $m$, made by two disconnected components, whose diameter satisfies

$$\text{diam}(E_*) \geq C_o,$$

for some $C_o > 0$.

Equivalently, there exists $\bar{\varepsilon} = \bar{\varepsilon}(\alpha, s) > 0$ such that, if $\varepsilon \in (0, \bar{\varepsilon})$, there exists a bounded set $E \subset \mathbb{R}$ which is a solution of (3), which is made by two disconnected components, whose diameter satisfies
diam(E) \geq C_\varepsilon \varepsilon^{-\frac{1}{1-s-\alpha}}.

In particular, the diameter of E is not bounded uniformly in \varepsilon.

One of the main tools in the proof of theorem 1 is a nonlocal version of Alexandrov’s theorem, recently proved in [8], which states that regular sets with almost constant fractional mean curvature are necessarily balls. This result can be applied to solutions to (3), after deriving suitable estimates on the potential \( V_E \).

We point out that such quantitative Alexandrov’s theorem does not hold in the local setting, where it is known that a set with almost constant mean curvature is close to a family of tangent balls (see [7]), and this is the main obstruction for extending our result to the case \( s = 1 \), that is, to the functional in (1).

The plan of the paper is the following: in section 2 we provide some preliminary estimates on the potential \( V_E \) and on its gradient, which will be useful in the proof of theorem 1; in section 3 we prove theorem 1; finally in section 4 we prove theorem 2, giving an explicit example of a one-dimensional set, composed by two disjoint segments, which is a critical point of (2) and has arbitrarily small volume.

2. Potential estimates

In this section we provide some bounds on the potential \( V \) and on its derivatives that will be used in the proof of the main results.

Lemma 3. Let \( B \) be a ball centered at the origin with \( |B| = |E| \). Then, for any \( x \in \mathbb{R}^n \),

\[
V_E(x) \leq V_0(0) \leq C,
\]

for some \( C > 0 \).

Proof. Let \( \rho > 0 \) be the radius of \( B \). In this way, we have that \( x + B = B_\rho(x) \). Also, if \( y \in B_\rho(x) \setminus E \), then \( |x - y| \leq \rho \) and so

\[
\int_{B_\rho \setminus E} \frac{dy}{|x - y|^\alpha} \geq \int_{B_\rho \setminus E} \frac{dy}{\rho^\alpha} = \frac{|B_\rho \setminus E|}{\rho^\alpha}.
\]

Similarly, if \( y \in E \setminus B_\rho(x) \), then \( |x - y| \geq \rho \) and so

\[
\int_{E \setminus B_\rho(x)} \frac{dy}{|x - y|^\alpha} \leq \frac{|E \setminus B_\rho(x)|}{\rho^\alpha}.
\]

Moreover

\[
|E \setminus B_\rho(x)| = |E| - |E \cap B_\rho(x)| = |B_\rho(x)| - |B_\rho(x) \cap E| = |B_\rho(x) \setminus E|.
\]

Consequently,

\[
\int_{E \setminus B_\rho(x)} \frac{dy}{|x - y|^\alpha} \leq \int_{B_\rho \setminus E} \frac{dy}{|x - y|^\alpha}.
\]

Therefore, summing the contributions in \( E \cap B_\rho(x) \) to both sides of this inequality, we obtain that

\[
\int_E \frac{dy}{|x - y|^\alpha} \leq \int_{B_\rho(x)} \frac{dy}{|x - y|^\alpha}.
\]

This and the integrability of the kernel imply the desired result. \( \square \)
Following are additional potential estimates:

**Lemma 4.** We have that

\[ \int_E \nabla V_\ell(x) \cdot x \, dx = -\frac{\alpha}{2} \int_E V_\ell(x) \, dx \]  

(10)

and

\[ \int_{\partial E} V_\ell(x) \cdot \nu(x) \, d\mathcal{H}^{n-1}(x) = \left( n - \frac{\alpha}{2} \right) \int_E V_\ell(x) \, dx, \]  

(11)

where \( \nu \) is the external normal to \( E \). Moreover,

\[ |\nabla V_\ell(x)| \leq C, \]  

(12)

for any \( x \in \mathbb{R}^n \), for a suitable \( C > 0 \).

**Proof.** We observe that

\[ \nabla V_\ell(x) = -\alpha \int_E \frac{(x - y) \, dy}{|x - y|^{n+2}}, \]  

(13)

so we can write

\[ \beta := \int_E \nabla V_\ell(x) \cdot x \, dx = -\alpha \int_{E \times E} \frac{(x - y) \cdot x \, dx \, dy}{|x - y|^{n+2}}. \]

Since the role played by the variable in the latter integral is symmetric, we can also write

\[ \beta = -\alpha \int_{E \times E} \frac{(y - x) \cdot y \, dx \, dy}{|x - y|^{n+2}}. \]

As a consequence

\[ 2\beta = -\alpha \int_{E \times E} \frac{(x - y) \cdot x \, dx \, dy}{|x - y|^{n+2}} - \alpha \int_{E \times E} \frac{(y - x) \cdot y \, dx \, dy}{|x - y|^{n+2}} \]

\[ = -\alpha \int_{E \times E} \frac{(x - y) \cdot (x - y) \, dx \, dy}{|x - y|^{n+2}} = -\alpha \int_{E \times E} \frac{dx \, dy}{|x - y|^n}. \]

This establishes (10).

Now we use the divergence theorem and (10) to see that

\[ \int_{\partial E} V_\ell(x) \cdot \nu(x) \, d\mathcal{H}^{n-1}(x) = \int_E \text{div} (V_\ell(x) \cdot x) \, dx \]

\[ = n \int_E V_\ell(x) \, dx + \int_E \nabla V_\ell(x) \cdot x \, dx \]

\[ = \left( n - \frac{\alpha}{2} \right) \int_E V_\ell(x) \, dx, \]

and so we have proved (11).
Finally, by (13),
\[ |\nabla V_{\xi}(x)| \leq \alpha \int_E \frac{dy}{|x - y|^{n+\Gamma}}, \]

hence (12) follows as in lemma 3 (replacing $\alpha$ there with $\alpha + 1 \in (0, n)$).

With this, we can show that smooth critical points possess a uniform bound on $\lambda_{\xi}$ in the Euler–Lagrange equation in (3):

**Corollary 5.** There exist $C_1, C_2 > 0$ such that
\[ |\lambda_{\xi} - C_1 P_{\xi}(E)| \leq C_2 \varepsilon. \]

**Proof.** Given a vector field $X \in C^\infty_0(\mathbb{R}^n)$, we denote, for any small $t > 0$, by $\Phi^t$ the flow induced by $X$, as defined by the Cauchy problem
\[
\begin{cases}
\partial_t \Phi^t(x) = X(\Phi^t(x)), \\
\Phi^0(x) = x.
\end{cases}
\]

Then (up to normalizing constants that we neglect, see e.g. Formula (6.12) in [12]), we have that
\[ \int_{\partial E} \rho_{E}(x) X(x) \cdot \nu(x) \, d\mathcal{H}^{n-1}(x), \]

being $\nu$ the external normal of $E$.

Now, by taking $X(x) := x$ in the vicinity of $E$, we have that
\[ \Phi^t(x) = x + tX(x) + O(t^2) = (1 + t)x + O(t^2) \]

and so $|\Phi^t(E)| = (1 + t + O(t^2)) |E|$. Therefore, by scaling, we have that
\[ P_t(\Phi^t(E)) = (1 + t + O(t^2))^{n-1} P_t(E) \]

and thus
\[ \frac{\partial}{\partial t} P_t(\Phi^t(E)) \bigg|_{t=0} = (n - s) P_t(E). \]

Comparing this and (14), we obtain
\[ P_t(E) = \int_{\partial E} \rho_{E}(x) x \cdot \nu(x) \, d\mathcal{H}^{n-1}(x), \]

up to multiplicative normalization constants that we neglect.

Also, by the divergence theorem,
\[ \int_{\partial E} x \cdot \nu(x) \, d\mathcal{H}^{n-1}(x) = \int_E \text{div}_x \, dx = n |E|. \]

Hence, by (3), (15) and lemma 4, up to multiplicative constants,
\[
\lambda_c \ |E| = \int_{\partial E} \lambda_c \cdot \nu(x) \ d\mathcal{H}^{n-1}(x) \\
= \int_{\partial E} \kappa_\nu(x) \cdot \nu(x) \ d\mathcal{H}^{n-1}(x) + \varepsilon \int_{\partial E} V_\varepsilon(x) \cdot \nu(x) \ d\mathcal{H}^{n-1}(x) \\
= P_\varepsilon(E) + \varepsilon \int_E V_\varepsilon(x) \ d\mathbf{x}.
\]

(16)

Also, by lemma 3,
\[
\int_E V_\varepsilon(x) \ d\mathbf{x} \leq C \ |E|.
\]

From this, (16) and the volume constraint \(|E| = 1\), the desired result plainly follows. \(\square\)

Now we control the tangential gradient of \(V_\varepsilon\):

**Lemma 6.** There exists \(\mu_0 > 0\) with the following property: for all \(\mu \in [0, \mu_0]\), if \(E \subset \mathbb{R}^n\) is such that \(E = T(B)\), where \(B\) is a ball with \(\|B\| = \|E\|\) and \(T : \mathbb{R}^n \to \mathbb{R}^n\) is a diffeomorphism with
\[
\|T - \text{Id}\|_{C^0(\bar{B})} \leq \mu,
\]
then
\[
|\nabla V_\varepsilon(x) \cdot \tau_\varepsilon(x)| \leq C\mu,
\]
for some \(C > 0\), where \(\tau_\varepsilon\) denotes the tangential vector to \(\partial E\).

**Proof.** We define \(\bar{x} := T^{-1}(x)\) and
\[
\tau_\varepsilon(x) := D T^{-1}(x) \tau_\varepsilon(x) = (DT(x))^{-1} \tau_\varepsilon(x).
\]

Notice that \(\tau_\varepsilon(\bar{x})\) is a tangent vector to \(\partial B\) at \(\bar{x} \in \partial B\). Also, by rotational symmetry, the function \(V_\varepsilon\) is constant along \(\partial B\), and therefore
\[
\nabla V_\varepsilon(\bar{x}) \cdot \tau_\varepsilon(\bar{x}) = 0.
\]

Moreover, by (13) and using the substitution \(\bar{y} := T^{-1}(y)\),
\[
\nabla V_\varepsilon(x) \cdot \tau_\varepsilon(x) = -\alpha \int_E \frac{(x - y) \cdot \tau_\varepsilon(x)}{|x - y|^{n+2}} \ dy \\
= -\alpha \int_B \frac{(T(\bar{x}) - T(\bar{y})) \cdot (DT(\bar{x}) \tau_\varepsilon(\bar{x}))}{|T(\bar{x}) - T(\bar{y})|^{n+2}} |\det DT(\bar{y})| \ d\bar{y}.
\]

(19)

Now, by (17),
\[
|DT(\bar{x}) \tau_\varepsilon(\bar{x}) - \tau_\varepsilon(\bar{x})| \leq C\mu,
\]
\[
|\det DT(\bar{y}) - 1| \leq C\mu,
\]
and
\[
|T(x) - T(y) - (x - y)| \leq \int_0^1 |(DT - \text{Id})(t\bar{y} + (1 - t)\bar{x})| \ dt \ |x - y| \leq C\mu \ |x - y|.
\]

(20)

for some \(C > 0\), and so, taking \(\mu\) sufficiently small,
\[
(1 - C\mu) \ |x - y| \leq |T(x) - T(y)| \leq (1 + C\mu) \ |x - y|.
\]
which in turn implies that
\[
\left| \frac{1}{|T(\bar{x}) - T(\bar{y})|^n} - \frac{1}{|\bar{x} - \bar{y}|^{n+2}} \right| = \frac{1}{|\bar{x} - \bar{y}|^{n+2}} \left( 1 - \frac{|\bar{x} - \bar{y}|^{n+2}}{|T(\bar{x}) - T(\bar{y})|^{n+2}} \right) \leq C \mu,
\]
up to renaming \( C > 0 \). Using this and (20) inside (19), we obtain that
\[
\frac{1}{\alpha} \left\| \nabla V_{\delta}(\bar{x}) - \nabla V_{\delta}(\bar{y}) \right\|
\]
\[
= \left| \int_B \frac{(\bar{x} - \bar{y}) \cdot (DT(\bar{x}) \tau(\bar{x}))}{|T(\bar{x}) - T(\bar{y})|^{n+2}} \, |\text{det} DT(\bar{y})| \, d\bar{y} - \int_B \frac{(\bar{x} - \bar{y}) \cdot \tau(\bar{x})}{|\bar{x} - \bar{y}|^{n+2}} \, d\bar{y} \right|
\]
\[
\leq C \mu \int_B \frac{d\bar{y}}{|\bar{x} - \bar{y}|^{n+1}}
\]
\[
\leq C \mu,
\]
possibly changing \( C > 0 \) from one line to another. From this estimate and (18), the desired result plainly follows.

\section{Proof of theorem 1}

Given a set \( E \), we define the following quantities:
\[
\delta_\varepsilon(E) := \sup_{x,y \in E \atop x \neq y} \frac{|s_\varepsilon(x) - s_\varepsilon(y)|}{|x - y|},
\]
\[
\eta_\varepsilon(E) := \frac{(\text{diam}(E))^{n+1}}{|E|^2} \delta_\varepsilon(E)
\]
and
\[
\rho(E) := \inf \left\{ \frac{R - r}{\text{diam}(E)} \right\}
\]
with \( p \in E \), \( B_r(p) \subseteq E \subseteq B_{\rho}(p) \).

In this setting, the following result holds true (see theorem 1.2 of [8]):
Theorem 7. If $E$ is a bounded open set with boundary of class $C^{2,\alpha}$, for some $\alpha > s$, then there exists a dimensional constant $C > 0$ such that

$$\rho(E) \leq C \eta(E). \quad (24)$$

Moreover, according to theorem 1.5 in [8], we have that:

Theorem 8. Assume that $E$ is a bounded open set with boundary of class $C^{2,\alpha}$, for some $\alpha > s$. Suppose that

$$B_{1 - 2\rho(E)} \subseteq E \subseteq B_1.$$

Then, there exists $\eta(n, s) > 0$ such that the following holds. If $\eta(E) \leq \eta(n, s)$ then there exists a map $F : \partial B_1 \to \mathbb{R}^n$ of class $C^{\alpha, \tau}$ for any $\tau < s$, such that $F(\partial B_1) = \partial E$ and

$$\|F - \text{Id}\|_{C^{\alpha, \tau}(\partial B_1)} \leq C \eta(E),$$

for some $C > 0$, depending on $n$, $s$ and $\tau$.

With this, we can now complete the proof of theorem 1 by arguing as follows. By a spatial dilation, we replace $E$ with a critical point $\tilde{E}$ of the functional $\varepsilon F$, under the volume constraint $\|E\| = 1$. To this aim, we define

$$E := m^{\frac{1}{n}} \tilde{E}, \quad \varepsilon := m^{1 - \frac{\alpha}{2} + \frac{\pi}{4}}.$$

In particular $\text{diam}(E) = m^{-\frac{1}{2}} \text{diam}(\tilde{E})$ and thus, by (6) and (7), condition (8) becomes

$$\varepsilon (\text{diam}(E))^{2n+s+1} = \left( \varepsilon^{\frac{1}{2n+s+1}} \cdot m^{-\frac{1}{2}} \text{diam}(\tilde{E}) \right)^{2n+s+1} = \left( \frac{m^{\frac{\alpha}{2} - s + \frac{1}{2}}}{\varepsilon} \right)^{2n+s+1} \leq C \varepsilon^{2n+s+1}, \quad (25)$$

which is supposed to be a small quantity.

Also, the Euler–Lagrange equation in (3) holds true. Therefore, recalling (21), we have that

$$\delta_\varepsilon(E) = \sup_{x, y \in E} \frac{|c \in V_{\varepsilon}(x) - \lambda_c - (c \in V_{\varepsilon}(y) - \lambda_c)|}{|x - y|} = c \varepsilon \sup_{x, y \in E} \frac{|V_{\varepsilon}(x) - V_{\varepsilon}(y)|}{|x - y|}. \quad (26)$$

Thus, by (12),

$$\delta_\varepsilon(E) \leq c \varepsilon \sup_{x, y \in E} \frac{|V_{\varepsilon}(x) - V_{\varepsilon}(y)|}{|x - y|} \leq C \varepsilon, \quad (27)$$

for some $C > 0$. Now, in the setting of (22) and (23), by (24) we have that

$$\rho(E) \leq C \eta(E), \quad (28)$$

up to renaming $C > 0$. Also, by (22) and (27) we get

$$\eta_\varepsilon(E) \leq C (\text{diam}(E))^{2n+s+1} \varepsilon. \quad (29)$$
This and (25) give that $\eta(E)$ is small if so is $c_\alpha$, hence we are in the position to apply theorem 8. In particular, we obtain that $\partial E = F(\partial B)$, where $B$ is a ball with volume $m$, with
$$
\|F - \text{Id}\|_{C(\partial B)} \leq C \eta(E),
$$
up to renaming $C > 0$. That is, if we set $T(x) := |x| \frac{1}{|\nabla x|}$ we have that $E = T(B)$ and
$$
\|T - \text{Id}\|_{C(\partial B)} \leq C \eta(E).
$$
This says that we are in the setting of lemma 6, with $\mu := C \eta(E)$. As a consequence, we obtain that
$$
\left| \nabla V_{\varepsilon}(x) \right| \leq C \eta(E),
$$
for some $C > 0$. Hence, we insert this into (26) and we find
$$
\delta_\varepsilon(E) \leq C \varepsilon \eta(E),
$$
up to renaming $C > 0$. Accordingly, in view of (22) and (25),
$$
\delta_\varepsilon(E) \leq C \varepsilon (\text{diam}(E))^{2n+s+1} \delta_\varepsilon(E) \leq C \varepsilon \eta(E) \leq \frac{\delta_\varepsilon(E)}{2},
$$
if $c_\alpha$ is small enough. This implies that $\delta_\varepsilon(E) = 0$.
So, by (22), we have that $\eta_\varepsilon(E) = 0$ and then, by (28), also $\rho(E) = 0$, which says that $E$ is a ball, as desired.

4. Proof of theorem 2

We let
$$
E := \left(0, \frac{1}{2}\right) \cup \left(d, d + \frac{1}{2}\right),
$$
for some $d > 1/2$, that we choose appropriately in order to fulfill (3).

By (5) and (4), for any $x \in \{0, 1/2, d, d + 1/2\}$,
$$
\zeta_\varepsilon(x) := \kappa_\varepsilon(x) + c \varepsilon V_{\varepsilon}(x)
$$
$$
= \int_{-\infty}^{0} \frac{dy}{|y|^{1+s}} - \int_{0}^{1/2} \frac{dy}{|y|^{1+s}} + \int_{1/2}^{d} \frac{dy}{|y|^{1+s}}
- \int_{d+1/2}^{\infty} \frac{dy}{|y|^{1+s}} + \int_{d+1/2}^{\infty} \frac{dy}{|y|^{1+s}}
$$
$$
+ c \varepsilon \int_{0}^{1/2} \frac{dy}{|y|^{1+s}} + c \varepsilon \int_{d}^{d+1/2} \frac{dy}{|y|^{1+s}}.
$$

By symmetry (i.e. using the substitution $y := (d + 1/2) - y$), we see that
$$
\zeta_\varepsilon(0) = \zeta_\varepsilon(d + 1/2) \quad \text{and} \quad \zeta_\varepsilon\left(\frac{1}{2}\right) = \zeta_\varepsilon(d). \quad (30)
$$

Now we prove that we can choose $d > 1/2$ in such a way that
$$
\zeta_\varepsilon(0) = \zeta_\varepsilon\left(\frac{1}{2}\right). \quad (31)
$$
To this aim, we compute

\[ f(d) := \zeta(d \left( \frac{1}{2} \right)) - \zeta(d(0)) \]

\[ = \int_{-\infty}^{0} \frac{dy}{|y - 1/2||^{d+1}} - \int_{0}^{1/2} \frac{dy}{|y - 1/2||^{d+1}} + \int_{1/2}^{d} \frac{dy}{|y - 1/2||^{d+1}} - \int_{d}^{\infty} \frac{dy}{|y - 1/2||^{d+1}} \]

\[ = \int_{-\infty}^{0} \frac{dy}{|y + s||^{d+1}} + \int_{0}^{1/2} \frac{dy}{|y + s||^{d+1}} - \int_{1/2}^{d} \frac{dy}{|y + s||^{d+1}} + \int_{d}^{\infty} \frac{dy}{|y + s||^{d+1}} \]

\[ = \int_{-\infty}^{0} \frac{dy}{|y + s||^{d+1}} + \int_{0}^{1/2} \frac{dy}{|y + s||^{d+1}} - \int_{1/2}^{d} \frac{dy}{|y + s||^{d+1}} + \int_{d}^{\infty} \frac{dy}{|y + s||^{d+1}} \]

Now we use that, for any \( \beta \in \mathbb{R} \) and \( \delta > 0 \) small,

\[ 2(1 - \delta)\beta - (1 + \delta)\beta = -\beta(\beta - 1)\delta^2 + O(\delta^3), \]

therefore, for large \( d \),

\[ f(d) = \frac{2d^{-s}}{s} \left[ 2 - \left(1 - \frac{1}{2d}\right)^{-1} - \left(1 + \frac{1}{2d}\right)^{-1} \right] \]

\[ + \frac{c\varepsilon d^{-s}}{1 - \alpha} \left[ 2 - \left(1 - \frac{1}{2d}\right)^{-\alpha} - \left(1 + \frac{1}{2d}\right)^{-\alpha} \right] \]

\[ = \frac{2d^{-s}}{s} \left[ \frac{-s(1 + s)}{4d^2} + O(d^{-3}) \right] + \frac{c\varepsilon d^{-s}}{1 - \alpha} \left[ \frac{\alpha(1 - \alpha)}{4d^2} + O(d^{-3}) \right] \]

\[ = d^{-\alpha} \left( \frac{c\varepsilon}{4} - \frac{(1 + s)d^{1-s+\alpha}}{2} + O(d^{-2-s+\alpha}) + O(d^{-1}) \right) \]

\[ = d^{-\alpha} g(d), \quad (32) \]
where

$$g(d) := \frac{c\alpha\varepsilon}{4} - \frac{(1 + s)d^{1-s+\alpha}}{2} + O(d^{-2-s+\alpha}) + O(\varepsilon d^{-1}).$$

Notice that

$$\lim_{d \to +\infty} g(d) = \frac{c\alpha\varepsilon}{4} > 0.$$  \hfill (33)

Also, if

$$d_\varepsilon := \left( \frac{1 + s}{c\alpha\varepsilon} \right)^{\frac{1}{1+s-\alpha}},$$

we have that

$$g(d_\varepsilon) = -\frac{c\alpha\varepsilon}{4} + O(\varepsilon^{1+\frac{1}{1+s-\alpha}}) \leq -\frac{c\alpha\varepsilon}{8} < 0,$$

if \( \varepsilon \) is sufficiently small.

From this and (33) we obtain that there exists an appropriate \( d > d_\varepsilon \) for which \( g(d) = 0 \), and thus, recalling (32), we obtain that \( f(d) = 0 \), which proves (31).

Now, from (30) and (31), we deduce that

$$\zeta_{\varepsilon}(0) = \zeta_{\varepsilon}\left(d + \frac{1}{2}\right) = \zeta_{\varepsilon}\left(\frac{1}{2}\right) = \zeta_{\varepsilon}(d) =: \lambda,$$

for some \( \lambda \in \mathbb{R} \), that is

$$\kappa_{\varepsilon}(x) + c\varepsilon V_\varepsilon(x) = \lambda$$

for any \( x \in \partial E \), as desired.

Acknowledgments

Part of this work was carried out while Serena Dipierro and Enrico Valdinoci were visiting the University of Pisa, which they wish to thank for the hospitality.

This work has been supported by the Alexander von Humboldt Foundation, the ERC grant 277749 E.P.S.I.L.O.N. ‘Elliptic Pde’s and Symmetry of Interfaces and Layers for Odd Nonlinearities’, the PRIN grant 201274FYK7 ‘Aspetti variazionali e perturbativi nei problemi differenziali nonlineari’ and the University of Pisa grant PRA- 2015-0017.

Finally, the authors wish to thank Giulio Ciraolo and Cyrill Muratov for useful conversations on the subject of this paper.
