Rank-initial embeddings of non-standard models of set theory

Abstract

A theoretical development is carried to establish fundamental results about rank-initial embeddings and automorphisms of countable non-standard models of set theory, with a keen eye for their sets of fixed points. These results are then combined into a "geometric technique" used to prove several results about countable non-standard models of set theory.

In particular, back-and-forth constructions are carried out to establish various generalizations and refinements of Friedman's theorem on the existence of rank-initial embeddings between countable non-standard models of the fragment $\mathsf{KP}^\Sigma^1$-Separation of $\mathsf{ZF}$; and Gaifman's technique of iterated ultrapowers is employed to show that any countable model of $\mathsf{GBC}$ + “Ord is weakly compact” can be elementarily rank-end-extended to models with well-behaved automorphisms whose sets of fixed points equal the original model. These theoretical developments are then utilized to prove various results relating self-embeddings, automorphisms, their sets of fixed points, strong rank-cuts, and set theories of different strengths. Two examples: The notion of “strong rank-cut” is characterized (i) in terms of the theory $\mathsf{GBC}$ + “Ord is weakly compact”, and (ii) in terms of fixed-point sets of self-embeddings.

1 Introduction

In [Friedman, 1973] Friedman famously invented an ingenious back-and-forth construction to show that every non-standard countable model of a certain fragment of $\mathsf{ZF}$ (or $\mathsf{PA}$) has a proper self-embedding. He actually proved a more general result, and his technique was later used to prove sharper results on non-standard models of arithmetic under additional assumptions. On a parallel track, Ramsey's theorem was used in [Ehrenfeucht, Mostowski, 1956] to show that any first-order theory with an infinite model has a model with a non-trivial automorphism. In particular, there are models of $\mathsf{PA}$, $\mathsf{ZFC}$, etc. with non-trivial automorphisms. Later on, Gaifman refined this technique considerably in the domain of models of arithmetic, showing that any countable model $\mathcal{M}$ of $\mathsf{PA}$ can be elementarily end-extended to a model $\mathcal{N}$ with an

Acknowledgement: This paper presents a portion of the results in the author’s Ph.D. Thesis [Gorbow, 2018], which was carried out at The University of Gothenburg, under close supervision of Ali Enayat.

Keywords: Set theory, $\mathsf{KP}$, $\mathsf{ZF}$, $\mathsf{GBC}$, Weakly compact, Nonstandard model, Embedding, Self-embedding, Automorphism, Fixed point, Strong cut, Iterated ultrapower, Recursively saturated
automorphism \( j : \mathcal{N} \rightarrow \mathcal{N} \) whose set of fixed points is precisely \( M \) \cite{Gaifman, 1976}. This was facilitated by the technical breakthrough of iterated ultrapowers, introduced by Gaifman and later adapted by Kunen to a set theoretical setting.

This paper generalizes and refines these two theorems in the domain of non-standard models of set theory, and combines them into a geometric machinery which is used to prove several new results. In the course of this project we also take the opportunity to generalize some more related results from arithmetic to set theory.

These results require a few definitions.

The Takahashi hierarchy, presented e.g. in \cite{Takahashi, 1972} (and in Section 3 of the present paper), is similar to the well-known Lévy hierarchy, but any quantifiers of the forms \( \exists x \in y, \forall x \in y, \forall x \subseteq y \) are considered bounded. \( \Delta^P_0 \) is the set of theorem formulae with only bounded quantifiers in that sense, and \( \Sigma^P_n \) and \( \Pi^P_n \) are then defined recursively in the usual way for all \( n \in \mathbb{N} \). KP\(^P\) (presented in Section 3) is the set theory axiomatized by Extensionality, Pair, Union, Powerset, Infinity, \( \Delta^P_0\)-Separation, \( \Delta^P_0\)-Collection and \( \Pi^P_1\)-Foundation.

Let us now go through some notions of substructure relevant to set theory (these are explained in more detail in Section 6). Let \( M \models \text{KP}^P \). A rank-initial substructure \( S \) of \( M \) is a submodel that is downwards closed in ranks (so if \( s \in S \) and \( M \models \text{rank}(m) \leq \text{rank}(s) \), then \( m \in S \) ). It is a rank-cut if, moreover, there is an infinite strictly descending downwards cofinal sequence of ordinals in \( M \setminus S \). It is a strong rank-cut if, moreover, for every function \( f : \text{Ord}^S \rightarrow \text{Ord}^M \) coded in \( M \) (in the sense that \( M \) believes there is a function \( f \) whose externalization restricted to \( \text{Ord}^S \) equals \( f \)), there is an ordinal \( \mu \in M \setminus S \) such that \( f(\xi) \notin S \Leftrightarrow f(\xi) > \mu \). Note that these notions for substructures also make sense for embeddings.

If (the interpretation of the element-relation in) \( M \) is well-founded, then we say that \( M \) is a standard model, and otherwise we say that it is non-standard. The largest well-founded rank-initial substructure of \( M \) exists. It is called the well-founded part of \( M \) and is denoted WFP(\( M \)). It turns out that WFP(\( M \)) is a rank-cut of \( M \).

Suppose that \( M \) is a model of KP\(^P\) with a proper rank-cut \( S \). If \( A \subseteq S \), then \( A \) is coded in \( M \) if there is \( a \in M \) such that \( \{ x \in S \mid M \models x \in a \} = A \). The standard system of \( M \) over \( S \), denoted SSy\(_S(M)\) is the second-order structure obtained by expanding \( S \) with all the subsets of \( S \) coded in \( M \). We define SSy\(_M(M)\) = SSy\(_{WFP(M)}(M)\).

Section 4 is concerned with proving various existence results for embeddings between countable non-standard models of fragments of ZFC. Friedman showed that for any countable non-standard models \( M \) and \( N \) of

\[
\text{KP}^P + \Sigma_1\text{-Separation} + \text{Foundation},
\]

and \( S \) such that

\[
S = \text{WFP}(M) = \text{WFP}(N),
\]

there is a proper rank-initial embedding of \( M \) into \( N \) iff the \( \Sigma_1^P \)-theory of \( M \) with parameters in \( S \) is included in the corresponding theory of \( N \) and SSy\(_S(M)\) = SSy\(_S(N)\).

Theorem 7.2 and Corollary 7.3 refine Friedman’s result in multiple ways. Firstly, we show that it holds for any common rank-cut \( S \) of \( M \) and \( N \) (not just for the standard cut); secondly, we show that it holds for all countable non-standard models of KP\(^P\) + \( \Sigma_1\)-Separation; thirdly we show that continuum many such embeddings can be obtained (generalizing a result from \( \text{Wilkie, 1973} \) for models of PA); and fourthly, we show that the embedding can be constructed so as to yield a rank-cut of the co-domain. Moreover, Theorem 7.3 establishes that for every

\[\text{Here Foundation is the axiom schema } \exists x. \phi(x) \rightarrow \exists y. (\phi(y) \land \forall v \in y. \neg \phi(v)), \text{ where } \phi \text{ ranges over formulae in the language of set theory.}\]
model $\mathcal{M}$ of $\text{KP}^+ + \Sigma_1$-Separation and every rank-cut $\mathcal{S}$ of $\mathcal{M}$, there is a rank-initial topless self-embedding of $\mathcal{M}$ which fixes $\mathcal{S}$ pointwise but moves some element on every rank above $\mathcal{S}$.

Friedman's insight lead to further developments in this direction in the model-theory of arithmetic. In particular, it was established for countable non-standard models of $\Sigma_1$. Ressayre showed, conversely, that if $\mathcal{M} \models \Sigma_0 + \text{exp}$, and for every $a \in \mathcal{M}$ there is a proper initial self-embedding of $\mathcal{M}$ which fixes every element $\mathcal{M}$-below $a$, then $\mathcal{M} \models \Sigma_1$ [Ressayre, 1987]. Theorem 7.10 is a set theoretic version of this optimality result, to the effect that if $\mathcal{M} \models \text{KP}^+$, and for every $a \in \mathcal{M}$ there is a proper rank-initial self-embedding of $\mathcal{M}$ which fixes every element that is an $\mathcal{M}$-member of $a$, then $\mathcal{M} \models \text{KP}^+ + \Sigma_1$-Separation.

Wilkie showed that for every countable non-standard model $\mathcal{M} \models \text{PA}$ and for every element $a$ of $\mathcal{M}$, there is a proper initial self-embedding whose image includes $a$ [Wilkie, 1977]. Theorem 7.10 and Corollary 7.12 generalize this result to set theory in refined form, e.g.: For every countable non-standard model $\mathcal{M} \models \text{KP}^+ + \Sigma_2^1$-Separation + $\Pi_2^1$-Foundation and for every element $a$ of $\mathcal{M}$, there is a proper initial self-embedding whose image includes $a$.

Yet another result in this vein is that the isomorphism types of countable recursively saturated models of PA only depends on the theory and standard system. A generalization of this result for PA (allowing common $\omega$-topless initial segments to be fixed) was proved in Kossak, Kotlarski, 1988. Theorem 7.15 is an analogous result for ZF.

Theorem 7.16 states that every countable recursively saturated model $\mathcal{M}$ of ZF, with a rank-cut $\mathcal{S}$, has an arbitrarily high rank-initial self-embedding $j$, fixing $\mathcal{S}$ pointwise, such that $j(\mathcal{M}) \prec \mathcal{M}$. This was originally proved in Ressayre, 1987, but we provide a new proof that is conceptually simpler.

of a countable recursively saturated model of ZFC + $V = \text{HOD}$ $^4$ $S$ is the fixed point set of an automorphism of $\mathcal{M}$ iff it is an elementary strong rank-cut.

Finally, we combine the Friedman- and Gaifman-style theorems to show (Theorem 9.9) that for any countable non-standard $\mathcal{M} \models \text{KP} + \Sigma^P_1$-Separation + Choice: $\mathcal{M}$ has a strong rank-cut isomorphic to $\mathcal{M}$ iff $\mathcal{M}$ expands to a model of GBC + “Ord is weakly compact”.

2 Motivation

It is a common theme throughout mathematics to study structures and how these structures relate to each other. Usually structures are related to each other by functions from one structure (the domain) to another (the co-domain), which preserve some of the structure involved. Since the study of such functions has turned out to be very fruitful in many branches of mathematics, it makes sense to apply this methodology to models of set theory as well.

When we consider models of such expressive theories as set theories, it is natural to compare structures by means of embeddings. Any embedding exhibits the domain as a substructure of the co-domain, but we can ask various questions about “how nicely” the domain can be embedded in the co-domain: Firstly, for any first-order structure we can ask if the embedding is elementary, i.e. whether the truth of every first-order sentence with parameters in the domain is preserved by the embedding. Secondly, for structures of set theory we can ask whether the domain is embedded “initially” in the co-domain. For set theory, the intuition of “initiality” may be captured by various different formal notions, of different strengths (see Section 6). The weakest notion of this form is called initiality and requires simply that the image of the embedding is downwards closed under $\in$, i.e. if $b$ is in the image, and the co-domain satisfies that $c \in b$, then $c$ is also in the image. This paper is concerned with rank-initial embeddings, defined by the stronger property that for every value of the embedding, every element of the co-domain of rank less than or equal to the rank of that value is also a value of the embedding. As noted in Section 4, KP $^P$ proves that the function $(\alpha \mapsto V_\alpha)$ is total on the ordinals, so it makes sense to consider a notion of embedding which preserves this structure $(\alpha \mapsto V_\alpha)$. And indeed, an embedding $i : \mathcal{M} \to \mathcal{N}$ is rank-initial iff $i$ is initial and $i(V^M_\alpha) = V^N_{i(\alpha)}$, for every ordinal $\alpha$ in $\mathcal{M}$ (see Corollary 6.11), so the choice to study the notion of rank-initial embedding is quite a natural in the setting of KP $^P$.

Between well-founded structures, all initial embeddings are trivial: This follows from the Mostowski collapse theorem (see Theorem 6.8 and Proposition 6.10(a)). In particular, if $i : \mathcal{M} \to \mathcal{N}$ is an initial embedding between well-founded extensional structures, then $\mathcal{M}$ and $\mathcal{N}$ are isomorphic to transitive sets (with the inherited $\in$-structure) $\mathcal{M}'$ and $\mathcal{N}'$, respectively, and $i$ is induced by the inclusion function of $\mathcal{M}'$ into $\mathcal{N}'$. So for a study of initial embeddings of models of set theory to yield any insight, we must turn our attention to non-standard models. As explained in the introduction, for non-standard models of arithmetic, several interesting results have been obtained that are either directly about initial embeddings between such models, or are proved by means of considering such embeddings. Thus a motivation for this work is to determine whether these generalize to the set theoretic setting, and if so, for which particular set theory. We give positive answers for suitable extensions of KP $^P$.

A deeper motivation lies in combining the techniques of Friedman and Gaifman into a geometric machinery. Several results and proofs of Section 9 testify to the versatility of this approach, where relationships are established between the theory GBC + “Ord is weakly compact”, strong cuts, rank-initial embeddings, and fixed point sets of rank-initial embeddings.

---

$^4$ $V = \text{HOD}$ is the statement that every set is hereditarily ordinal definable; see Section 5 for details.
3 Basic logic and model theory

This section contains basic material on logic and model theory typically found in introductory textbooks such as [Chang, Keisler, 1990]. An expanded version of this section with proofs of the results is found as §4.1 of [Gorbow, 2015].

We work with the usual first-order logic. A signature is a set of constant, function and relation symbols. The language of a signature is the set of well-formed formulas in the signature. The arity of function symbols, f, and relation symbols, R, are denoted arity(f) and arity(R), respectively. Models in a language are written as \( \mathcal{M}, \mathcal{N}, \) etc. They consist of interpretations of the symbols in the signature; for each symbol \( S \) in the signature, its interpretation in \( \mathcal{M} \) is denoted \( S^\mathcal{M} \). If \( X \) is a term, relation or function definable in the language over some theory under consideration, then \( X^\mathcal{M} \) denotes its interpretation in \( \mathcal{M} \).

The domain of \( \mathcal{M} \) is also denoted \( \mathcal{M} \), so \( a \in \mathcal{M} \) means that \( a \) is an element of the domain of \( \mathcal{M} \). Finite tuples are written as \( \vec{a} \), and the tuple \( \vec{a} \) considered as a set (forgetting the ordering of the coordinates) is also denoted \( \vec{a} \). Moreover, \( \vec{a} \in \mathcal{M} \) means that each coordinate of \( \vec{a} \) is an element of the domain of \( \mathcal{M} \). length(\( \vec{a} \)) denotes the number of coordinates in \( \vec{a} \). For each natural number \( k \in \{1, \ldots, \text{length}(\vec{a})\} \), \( \pi_k(\vec{a}) \) is the \( k \)-th coordinate of \( \vec{a} \). When a function \( f : A \to B \) is applied as \( f(\vec{a}) \) to a tuple \( \vec{a} \in A^n \), where \( n \in \mathbb{N} \), then it is evaluated coordinate-wise, so \( f(a_1, \ldots, a_n) = (f(a_1), \ldots, f(a_n)) \). If \( \Gamma \) is a set of formulae in a language and \( n \in \mathbb{N} \), then \( \Gamma[x_1, \ldots, x_n] \) denotes the subset of \( \Gamma \) of formulae all of whose free variables are in \( \{x_1, \ldots, x_n\} \).

The theory of a model \( \mathcal{M} \), denoted \( \text{Th}(\mathcal{M}) \), is the set of formulae in the language satisfied by \( \mathcal{M} \). If \( \Gamma \) is a subset of the language and \( S \subseteq \mathcal{M} \), then

\[
\text{Th}_{\Gamma,S}(\mathcal{M}) = \{ \phi(\vec{s}) \mid \phi \in \Gamma \land \vec{s} \in S \land (\mathcal{M}, \vec{s}) \models \phi(\vec{s}) \}.
\]

The standard model of arithmetic is denoted \( \mathbb{N} \).

\( \mathcal{L}^0 \) is the language of set theory, i.e. the set of all well-formed formulae generated by \( \{ \in \} \).

\( \mathcal{L}^1 \) is defined as a two-sorted language in the single binary relation symbol \( \{ \in \} \); we have a sort Class of classes (which covers the whole domain and whose variables and parameters are written in uppercase \( X, Y, Z, A, B, C, \) etc.) and a sort Set of sets (which is a subsort of Class and whose variables and parameters are written in lowercase \( x, y, z, a, b, c, \) etc.). The relation \( \in \) is a predicate on the derived sort Set \( \times \) Class.

Models in \( \mathcal{L}^1 \) are usually written in the form \( (\mathcal{M}, \mathcal{A}) \), where \( \mathcal{M} \) is an \( \mathcal{L}^0 \)-structure on the domain of sets, and \( \mathcal{A} \) is a set of classes. It is sometimes convenient to regard an \( \mathcal{L}^1 \)-structure \( (\mathcal{M}, \mathcal{A}) \) simply as its reduct \( \mathcal{M} \) to the language \( \mathcal{L}^0 \); for example, if \( (\mathcal{M}, \mathcal{A}) \) is an \( \mathcal{L}^1 \)-structure, then (unless otherwise stated), by an element of \( (\mathcal{M}, \mathcal{A}) \), is meant an element of sort Set.

The notions of substructure, embedding and isomorphism are defined in the usual way. An embedding is proper if it is not onto. We write \( \mathcal{M} \cong \mathcal{N} \) if \( \mathcal{M} \) and \( \mathcal{N} \) are isomorphic. If \( S \) is a common subset of \( \mathcal{M} \) and \( \mathcal{N} \), and there is an isomorphism between \( \mathcal{M} \) and \( \mathcal{N} \) fixing \( S \) pointwise, then we write \( \mathcal{M} \cong_S \mathcal{N} \).

An embedding \( f : \mathcal{M} \to \mathcal{N} \) of \( \mathcal{L} \)-structures is \( \Gamma \)-elementary, for some \( \Gamma \subseteq \mathcal{L} \), if for each formula \( \phi(\vec{x}) \) in \( \Gamma \), and for each \( \vec{m} \in \mathcal{M} \),

\[
\mathcal{M} \models \phi(\vec{m}) \iff \mathcal{N} \models \phi(f(\vec{m})).
\]

If there is such an embedding we write \( \mathcal{M} \preceq_{\Gamma,S} \mathcal{N} \). \( f \) is elementary if it \( \mathcal{L} \)-elementary.

It is also of interest to consider partial embeddings. \([\mathcal{M} \preceq_{\Gamma,S}^\omega \mathcal{N}]\) denotes the set of partial functions \( f \) from \( \mathcal{M} \) to \( \mathcal{N} \), with finite domain, fixing \( S \) pointwise, and such that for all \( \phi(\vec{x}) \in \Gamma \) and for all \( \vec{m} \in \mathcal{M} \),

\[
\mathcal{M} \models \phi(\vec{m}) \Rightarrow \mathcal{N} \models \phi(f(\vec{m})).
\]
Please note!: This definition uses ‘⇒’, as opposed to the ‘⇔’ used in the definition of ‘≥’.

If Γ is omitted, then it is assumed to be \( \mathcal{L}^0 \), and if \( S \) is omitted, then it is assumed to be \( \emptyset \).

Let \( \mathbb{P} = [\mathcal{M} \preceq^{\subseteq \Sigma} \mathcal{N}] \). We endow \( \mathbb{P} \) with the following partial order. For any \( f, g \in \mathbb{P} \),

\[
    f \preceq^p g \iff f \mid_{\text{dom}(g)} = g.
\]

In Section 3 we will introduce definitions for more types of embeddings that are relevant to the study of models of set theory.

The uniquely existential quantifier \( \exists x . \phi(x) \) is defined as \( \exists x . (\phi(x) \land (\forall y . \phi(y) \rightarrow y = x)) \). The bounded quantifiers, \( \forall u \in y . \phi(u, y) \) and \( \exists u \in y . \phi(u, y) \), are defined as \( \forall u . (u \in y \rightarrow \phi(u, y)) \) and \( \exists u . (u \in y \land \phi(u, y)) \), respectively. \( \Delta_0 \subseteq \mathcal{L}^0 \) is the set of formulae all of whose quantifiers are bounded. \( \Sigma_0 \) and \( \Pi_0 \) are defined as equal to \( \Delta_0 \). Recursively, for every \( n \in \mathbb{N} \): \( \Sigma_{n+1} \subseteq \mathcal{L}^0 \) is the set of formulae of the form \( \exists x . \phi \), where \( \phi \) is in \( \Pi_n \); and dually, \( \Pi_{n+1} \subseteq \mathcal{L}^0 \) is the set of formulae of the form \( \forall x . \phi \), where \( \phi \) is in \( \Sigma_n \). For each \( n \in \mathbb{N} \), \( \mathcal{B}_n \) is defined as the closure of \( \Sigma_n \) under Boolean connectives and bounded quantifiers.

Suppose a background \( \mathcal{L}^0 \)-theory \( T \) is given. For each \( n \in \mathbb{N} \) and each symbol ‘\( T \)’ \( \in \{ ' \Sigma', ' \Pi', ' \forall', ' \exists' \} \), \( \Gamma_n \) is defined as the set of formulae provably equivalent (in \( T \)) to a formula in \( \Gamma_n \). Moreover, for each \( n \in \mathbb{N} \), \( \Delta_n = \{ T \} \cap \Pi_n \). These sets of formulae are collectively called the Lévy hierarchy, and we say that they measure a formula’s Lévy complexity. Many facts about this hierarchy (in the context of ZFC) are established in [Takahashi, 1972]. It appears like these results also hold in the context of KPû (apart from its Theorem 6, which might require KPû + Choice).

When a set of formulae is denoted with a name that includes free variables, for example \( p(\vec{x}) \), then it is assumed that each formula in the set has at most the free variables \( \vec{x} \). Moreover, if \( \vec{a} \) is terms or elements of a model, then \( p(\vec{a}) = \{ \phi(\vec{a}) \mid \phi(\vec{x}) \in p(\vec{x}) \} \).

A type \( p(\vec{x}) \) over a theory \( T \) or over a model \( \mathcal{M} \), are defined in the usual way. Given a tuple \( \vec{a} \in \mathcal{M} \), a subset \( \Gamma \subseteq \mathcal{L} \) and a subset \( S \subseteq \mathcal{M} \), the \( \Gamma \)-type of \( \vec{a} \) over \( \mathcal{M} \) with parameters in \( S \) is the set \( \{ \phi(\vec{x}, \vec{b}) \mid \phi \in \Gamma \land \vec{b} \in S \land \mathcal{M} \models \phi(\vec{a}, \vec{b}) \} \), denoted \( \text{tp}_\Gamma,S(\vec{a}) \).

We fix a Gödel numbering of the syntactical objects in the languages \( \mathcal{L}^0 \) and \( \mathcal{L}^1 \), and assume that any syntactic object in these languages equals its Gödel number. A type \( p(\vec{x}, \vec{b}) \) over \( \mathcal{M} \) is recursive if \( \{ \phi(\vec{x}, \vec{y}) \mid \phi(\vec{x}, \vec{b}) \in p(\vec{x}, \vec{b}) \} \) is a recursive set, where \( \vec{a} \) denotes the Gödel code of \( \phi(\vec{x}, \vec{y}) \) (henceforth formulae will be identified with their Gödel codes). \( \mathcal{M} \) is recursively \( \Gamma \)-saturated if it realizes every recursive \( \Gamma \)-type over \( \mathcal{M} \).

The notions of poset (or partial order) and linear order are defined in the usual way.

Let \( \mathbb{P} \) be a poset. We say that a formula \( \phi(x) \) holds for unboundedly many \( x \in \mathbb{P} \), if for any \( a \in \mathbb{P} \), there is \( b >^p a \) such that \( \phi(b) \).

An embedding \( i : \mathbb{P} \rightarrow \mathbb{P}' \) of posets, is just a special case of embeddings of structures, i.e. it is an embedding of \( \{ \leq \} \)-structures. Let \( i : \mathbb{P} \rightarrow \mathbb{P}' \) be an embedding of posets. \( y \in \mathbb{P}' \) is an \( i \)-upper bound of \( x \) if \( \forall x \in \mathbb{P} . i(x) < y \). If such a \( y \) exists then \( i \) is \( i \)-bounded above. \( i \) is topless if it is bounded above but does not have a \( \mathbb{P} \)-least upper bound.

A self-embedding \( i : \mathbb{P} \rightarrow \mathbb{P} \) is \( i \)-contractive if for all \( x \in \mathbb{P} \), we have \( i(x) <^p x \).
Let $\mathbb{P}$ be a poset. Given $x \in \mathbb{P}$, define $\mathbb{P}_{\leq x}$ as the substructure of $\mathbb{P}$ on $\{y \in \mathbb{P} \mid y \leq x\}$; and similarly, if $X \in \mathbb{P}$, define $\mathbb{P}_{\leq X}$ as the substructure of $\mathbb{P}$ on $\{y \in \mathbb{P} \mid \exists x \in X, y \leq x\}$. We have analogous definitions for when ‘$<$’ is replaced by ‘$<$’, ‘$>$’ or ‘$>$’.

For any ordinal $\alpha$ and linearly ordered set $(\mathbb{L}, <^\mathbb{L})$, the lexicographic ordering on the set $\mathbb{L}^{<\alpha}$ is defined in the usual way and denoted $<^\text{lex}$.

Let $\mathbb{P}$ be a poset. A subset $\mathcal{D} \subseteq \mathbb{P}$ is dense if for any $x \in \mathbb{P}$ there is $y \in \mathcal{D}$ such that $y \leq x$. A filter $\mathcal{F}$ on $\mathbb{P}$ is a non-empty subset of $\mathbb{P}$, such that $\forall x, y \in \mathbb{P}, ((x \in \mathcal{F} \land x \leq y) \rightarrow y \in \mathcal{F})$ (upwards closed) and $\forall x, y \in \mathcal{F} \exists z (z \leq x \land z \leq y)$ (downwards directed). A filter $\mathcal{F}$ is an ultrafilter if it is maximal, i.e. if there is no filter $\mathcal{F}'$ on $\mathbb{P}$ such that $\mathcal{F} \subseteq \mathcal{F}'$. Let $\mathcal{D}$ be a set of dense subsets of $\mathbb{P}$. A filter $\mathcal{F}$ is $\mathcal{D}$-generic, if $\forall \mathcal{D} \in \mathcal{D}, \mathcal{D} \cap \mathcal{F} \neq \emptyset$.

**Lemma 3.1.** Let $\mathbb{P}$ be a poset with an element $p$. If $\mathcal{D}$ is a countable set of dense subsets of $\mathbb{P}$, then there is a $\mathcal{D}$-generic filter $\mathcal{F}$ on $\mathbb{P}$ containing $p$.

**Lemma 3.2.** Let $\mathbb{P}$ be a poset and let $\mathcal{F}$ be a filter on $\mathbb{P}$. There is an ultrafilter $\mathcal{U}$ such that $\mathcal{F} \subseteq \mathcal{U}$.

## 4 Power Kripke-Platek set theory

The set theory $\text{KP}^\mathbb{P}$ may be viewed as the natural extension of Kripke-Platek set theory $\text{KP}$ “generated” by adding the Powerset axiom.

**Axioms 4.1 (Power Kripke-Platek set theory, $\text{KP}^\mathbb{P}$).** $\text{KP}^\mathbb{P}$ is the $\mathcal{L}^0$-theory given by these axioms and axiom schemata:

- **Extensionality** $\forall x, y. (\forall u. u \in x \leftrightarrow u \in y) \rightarrow x = y$
- **Pair** $\forall u, v. \exists x. \forall w. (w \in x \leftrightarrow (w = u \lor w = v))$
- **Union** $\forall x. \exists y \forall r. (r \in u \leftrightarrow \exists v. r \in x \land v \in u)$
- **Powerset** $\forall u. \exists x. \forall v. (v \in x \leftrightarrow v \in u)$
- **Infinity** $\exists x. (\emptyset \in x \land \forall u \in x, \{u\} \in x)$
- **$\Delta_0^\mathcal{P}$-Separation** $\forall x, y. \forall u. (u \in y \leftrightarrow (u \in x \land \phi(u)))$
- **$\Delta_0^\mathcal{P}$-Collection** $\forall x, y. \forall u. (\exists v. \phi(u, v) \rightarrow \exists y. \forall u. \phi(u, v) \in x)\land \forall v. \phi(u, v))$
- **$\Pi_1^\mathcal{P}$-Foundation** $\exists x. \phi(x) \rightarrow \exists y. (\phi(y) \land \forall v. \phi(y, v))$

Above and in the following, if a schema named $\Gamma$-[name] is specified by a formula involving a meta-variable for a subformula (e.g. $\phi$ above), then this meta-variable ranges over $\Gamma$. If $\Gamma$ is omitted from such a name, then the formula ranges over $\mathcal{L}^0$.

We also consider these axioms and schemata:

- **Strong $\Gamma$-Collection** $\forall x \exists y \forall u. \exists u'. (\exists v. \phi(u, v) \rightarrow \exists u'. y \phi(u, v'))$
- **$\Gamma$-Replacement** $\forall x. \exists y. (\forall u \in x. \exists v. \phi(u, v) \rightarrow \exists y. \forall v. (v \in y \leftrightarrow \exists u. \phi(u, v)))$
- **Choice** $\forall x. ((\forall u \in x. u \neq \emptyset) \rightarrow \exists f : x \rightarrow \bigcup x. \forall u \in x. f(u) \in u)$.

Apart from adding the Powerset axiom, $\text{KP}^\mathbb{P}$ differs from $\text{KP}$ in that the schemata of Separation, Collection and Foundation are extended to broader sets of formulæ, using the Takahashi hierarchy instead of the Lévy hierarchy. ($\text{KP}$ has $\Delta_0$-Separation, $\Delta_0$-Collection and $\Pi_1$-Foundation.) Since

$$\mathcal{P}(u) = y \iff (\forall v \subseteq u. v \in y) \land \forall v \in y. \forall r \in v. r \in u),$$

the Takahashi hierarchy treats the powerset operation as a bounded operation. It is in this sense that $\text{KP}^\mathbb{P}$ is “generated” from $\text{KP}$ by adding powersets.
The theory KP has received a great deal of attention, because of its importance to Gödel’s L (the hierarchy of constructible sets), definability theory, recursion theory and infinitary logic. The “bible” on this subject is [Barwise, 1975]. The main sources on KP seem to be the papers by Friedman and Mathias that are discussed later on in this section.

There is of course much to say about what can and cannot be proved in these theories. KP proves $\Delta_1$-Separation, $\Sigma_1$-Collection and $\Sigma_1$-Replacement. KP proves $\Delta_1^P$-Separation, $\Sigma_1^P$-Collection and $\Sigma_1^P$-Replacement. Both theories enjoy a decent recursion theorem. In KP we have $\Sigma_1$-Recursion and in KP$^P$ we have $\Sigma_1^P$-Recursion. $\Gamma$-Recursion is the statement in the meta-theory (in relation to an object base theory) that for any $\psi(x,y) \in \Gamma$ provably defining a total function $G$ on the universe, there is $\phi(x,y) \in \Gamma$ provably defining a a total function $F$ on the universe, such that provably $\forall x. F(x) = G(F\upharpoonright x)$.

$\Sigma_1$-Recursion is quite important in that it enables development of first-order logic and model theory. Moreover, it enables KP to prove the totality of the rank-function, but (in the absence of Powerset) it is not sufficient to establish that the function $\alpha \mapsto V_\alpha$ is total on the ordinals. However, thanks to $\Sigma_1^P$-Recursion, KP$^P$ does prove the latter claim, and this is needed for certain arguments in Section 4, particularly in the proof of our Friedman-style embedding theorem. Also of interest, though not used in this paper, is that neither of the theories proves the existence of an uncountable ordinal. (This may be seen from the short discussion about the Church-Kleene ordinal later on in the section.) However, KP$^P$ augmented with the axiom of Choice proves the existence of an uncountable ordinal, essentially because Choice gives us that $\mathcal{P}(\omega)$ can be well-ordered.

There is also a philosophical reason for considering KP and KP$^P$, in that they encapsulate a more parsimonious ontology of sets than ZF. If $a$ is an element of an $L^\alpha$-structure $\mathcal{M}$, then $a_{\mathcal{M}}$ denotes the set $\{x \in M \mid \mathcal{M} \models x \in a\}$. A set $x$ is *transitive* if $\forall u \in x. u \subseteq x$. It is *supertransitive* if additionally $\forall u \in x. \forall v \subseteq u. v \in x$. The *transitive closure* $\text{TC}(x)$ of a set $x$ is its closure under elements of elements, i.e. the least superset of $x$ such that $\forall u \in \text{TC}(x). \forall r \in u. r \in \text{TC}(x)$. The *supertransitive closure* $\text{STC}(x)$ of a set $x$ is its closure under elements of elements and subsets of elements, i.e. the least superset of $x$ such that $\forall u \in \text{STC}(x). \forall r \in u. x \in \text{STC}(x)$ and $\forall u \in \text{STC}(x). \forall v \subseteq u. v \in \text{STC}(x)$. KP proves that $\text{TC}(x)$ exists for all $x$, and KP$^P$ proves that $\text{STC}(x)$ exists for all $x$.

If $\mathcal{M}$ is a model of KP, $a$ is an element of $\mathcal{M}$, and $\phi(x)$ is a $\Delta_0$-formula of set theory, then it is straightforward to show that

$$\mathcal{M} \models \phi(a) \iff (\text{TC}\mathcal{M}(\{a\})), \mathcal{M} \models \phi(a).$$

The reason for this equivalence is that a quantifier in a $\Delta_0$-formula can only range over a subset of the transitive closure of $\{a\}$.

Similarly, if $\mathcal{M}$ is a model of KP$^P$, $a$ is an element of $\mathcal{M}$, and $\phi(x)$ is a $\Delta_0^P$-formula of set theory, then

$$\mathcal{M} \models \phi(a) \iff (\text{STC}\mathcal{M}(\{a\})), \mathcal{M} \models \phi(a).$$

Thus, the Separation and Collection schemata of KP and KP$^P$ only apply to formulae whose truth depends exclusively on the part of the model which is “below” the parameters and free variables appearing in the formula (in the respective senses specified above).

Friedman’s groundbreaking paper [Friedman, 1973], established several important results in the model theory of KP$^P$. Section 4 is concerned with generalizing and refining one of these results (Theorem 4.1 of that paper), as well as related results. In its simplest form, this result is that every countable non-standard model of KP$^P + \Sigma_1^P$-Separation has a proper self-embedding.

A second important result of Friedman’s paper (its Theorem 2.3) is that every countable standard model of KP$^P$ is the well-founded part of a non-standard model of KP$^P$. 

8
Thirdly, let us also consider Theorem 2.6 of Friedman’s paper. This theorem says that any countable model of KP can be extended to a model of KP with the same ordinals. The ordinal height of a standard model of KP is the ordinal representing the order type of the ordinals of the model. An ordinal is said to be admissible if it is the ordinal height of some model of KP. This notion turns out to be closely connected with recursion theory. For example, the first admissible ordinal is the Church-Kleene ordinal $\omega^1_{CK}$, which may also be characterized as the least ordinal which is not order-isomorphic to a recursive well-ordering of the natural numbers. So in particular, Friedman’s theorem shows that every countable admissible ordinal is also the ordinal height of some model of KP.

Another important paper on KP is Mathias’s [Mathias, 2001], which contains a large body of results on weak set theories. See its Section 6 for results on KP. One of many results established there is its Theorem 6.47, which shows that KP + $V = L$ proves the consistency of KP, where $V = L$ is the statement that every set is Godel constructible.

From the perspective of this paper, the main KP-style set theory of interest is KP + $\Sigma^P_1$-Separation, because it is for non-standard countable models of this theory that Friedman’s embedding theorem holds universally. Returning to the philosophical discussion on parsimony above, this theory of affirm the existence of more sets, as arising from applying Separation to $\Sigma^P_1$-formulae. The truth of such formulae can be given a similar characterization as we gave for $\Delta^0_1$-formulae: If $M \models KP^P$, $p \in M$ and $\delta(x, y) \in \Delta^P_0$, then

$$M \models \exists x. \delta(x, p) \iff \exists a \in M. [(STC^M(\{a, p\}), M \models \delta(a, p)].$$

**Proposition 4.2.** Useful relationships between axioms to be considered:

(a) $KP^P + \Delta^P_0$-Separation, $\Sigma^P_1$-Collection, $\Sigma^P_2$-Replacement.

(b) $KP^P + \text{“the function } \alpha \mapsto V\alpha \text{ is total on the ordinals”}.$

(c) $KP^P + \Sigma^P_1$-Separation $\vdash$ Strong $\Sigma^P_1$-Collection.

(d) For each $n \in \mathbb{N}$, $KP^P + \Sigma^P_n$-Separation $\iff B^P_n$-Separation.

**Proof.** For (a) we refer to [Mathias, 2001]. The others are routine. \qed

We shall now establish some basic closure properties in the Takahashi hierarchy. These will often be used without explicit reference to this proposition.

**Proposition 4.3.** Take KP as base theory.

(a) $\Delta^P_1$ is closed under boolean connectives. Moreover, if $f$ is a $\Sigma^P_1$-function and $\phi \in \Delta^P_1$, then the formulae $\forall x \in f(y), \phi$, $\exists x \in f(y), \phi$, $\forall x \subseteq f(y), \phi$ and $\exists x \subseteq f(y), \phi$ are all in $\Delta^P_1$.

(b) $\Sigma^P_1$ is closed under disjunction and conjunction. Moreover, if $f$ is a $\Sigma^P_1$-function and $\phi \in \Sigma^P_1$, then the formulae $\forall x \in f(y), \phi$, $\exists x \in f(y), \phi$, $\forall x \subseteq f(y), \phi$ and $\exists x \subseteq f(y), \phi$ are all in $\Sigma^P_1$.

(c) If $f$ is a $\Sigma^P_1$-function, then it is a $\Delta^P_1$-function.

**Proof.** We follow the proof of Theorem 1 in [Takahashi, 1972]. Let $\phi, \psi$ be $L^0$-formulae. By mere logic,

$$\neg \exists x. \phi(x) \iff \forall x. \neg \phi(x),$$

$$\exists x. \phi(x) \land \exists y. \psi(y) \iff \exists x. \exists y. (\phi(x) \land \phi(y)),$$

$$\exists x. \phi(x) \lor \exists y. \psi(y) \iff \exists z. (\phi(z) \lor \psi(z)).$$
Assume that \( \phi \) and \( \psi \) are in \( \Sigma^P_1 \). By set-theory,
\[
\exists x. \exists y. \phi(x, y) \iff \exists z. \exists x \in z. \exists y \in z. \phi(x, y),
\]
\[
\forall u \in x. \exists y. \phi(u, x, y) \iff \exists z. \forall u \in x. \exists y \in z. \phi(u, x, y),
\]
\[
\forall u \subseteq x. \exists y. \phi(u, x, y) \iff \exists z. \forall u \subseteq x. \exists y \in z. \phi(u, x, y).
\]
In particular, the first equivalence follows from Pair, the second follows from \( \Sigma^P_1 \)-Collection, and the third follows from Powerset and \( \Sigma^P_1 \)-Collection.

Suppose that \( f \) is defined by a \( \Sigma^P_1 \)-formula \( F(x, y) \), such that \( f(x) = y \iff F(x, y) \). By considering the formula \( F'(x, y) \equiv \forall y'. (F(x, y') \rightarrow y = y') \), we see that \( f \) is actually a \( \Delta^P_1 \)-function. Now note that by logic, for any \( \phi \in \mathcal{L}^0 \),
\[
\exists x \in f(y). \phi(x, y) \iff \exists z. (f(y) = z \land \exists x \in z. \phi(x, y))
\]
\[
\iff \forall z. (f(y) = z \rightarrow \exists x \in z. \phi(x, y)).
\]
With all these equivalences at hand, the proposition is easily verified.

The fact that KP\(^P\) proves the existence of the \( V \)-hierarchy is very useful. For example, it enables the following result.

**Proposition 4.4.** For each \( 1 \leq k < \omega \), KP\(^P\) + \( \Sigma^P_k \)-Separation \( \vdash \) B\(^P_k\)-Foundation.

**Proof.** Recall that \( \Sigma^P_k \)-Separation implies B\(^P_k\)-Separation. Let \( \phi(x) \in B^P_k[x] \). Suppose there is \( a \) such that \( \phi(a) \). By B\(^P_k\)-Separation, let
\[
A = \{ x \in V_{\text{rank}(a)+1} \mid \phi(x) \},
\]
and note that \( a \in A \). By \( \Sigma_1 \)-Separation, let
\[
R = \{ \xi < \text{rank}(a) + 1 \mid \exists x \in A. \text{rank}(x) = \xi \}.
\]
Since \( R \) is a non-empty set of ordinals, it has a least element \( \rho \). Let \( a' \in A \) such that \( \text{rank}(a') = \rho \). Then we have \( \forall x \in a. \neg \phi(x) \), as desired.

## 5 ZFC, GBC and “Ord is weakly compact”

A set \( s \) is ordinal definable if there is \( n \in \mathbb{N} \), ordinals \( \alpha, \beta_1, \ldots, \beta_n \), and a formula \( \phi \), for which \( s \) is the unique set such that \( (V_\alpha, V_\alpha) \models \phi(s, \beta_1, \ldots, \beta_n) \). OD is defined as the class of ordinal definable sets. A set \( t \) is hereditarily ordinal definable if every element in the transitive closure of \( \{ t \} \) is ordinal definable. HOD is defined as the class of hereditarily ordinal definable sets.

ZFC plus the axiom
\[
V = \text{HOD} \quad \text{“every set is hereditarily ordinal definable”},
\]
has definable Skolem functions.
If \( L \) is an expansion of \( \mathcal{L}^0 \) with more symbols, then ZF(\( L \)) denotes the theory
\[
\text{ZF} + \text{L-Separation} + \text{L-Replacement},
\]
by which is meant that the schemata of Separation and Replacement are extended to all formulae in \( L \). ZFC(\( L \)) is defined analogously.
We will also consider the axiom “Ord is weakly compact”, in the context of GBC. It is defined as “Every binary tree of height Ord has a branch.” The new notions used in the definens are now to be defined. Let α be an ordinal. A binary tree is a (possibly class) structure \( \mathcal{T} \) with a binary relation \( \mathord{<}_T \), such that:

(i) Every element of \( \mathcal{T} \) (called a node) is a function from an ordinal to 2;
(ii) For every \( f \in \mathcal{T} \) and every ordinal \( \xi \prec \mathord{dom}(f) \), we have \( f \!estriction_{\xi} \in \mathcal{T} \);
(iii) For all \( f,g \in \mathcal{T} \),

\[
f \mathord{<_T} g \Leftrightarrow \mathord{dom}(f) \prec \mathord{dom}(g) \land g \!estriction_{\mathord{dom}(f)} = f;
\]

Suppose that \( \mathcal{T} \) is a binary tree. The height of \( \mathcal{T} \), denoted \( \mathord{height}(\mathcal{T}) \), is \( \{ \xi \mid \exists f \in \mathcal{T} \mathord{dom}(f) = \xi \} \) (which is either an ordinal or the class Ord). A branch in \( \mathcal{T} \) is a (possibly class) function \( F : \text{Ord} \to \mathcal{T} \), such that for all ordinals \( \xi \in \mathord{height}(\mathcal{T}) \), \( \mathord{dom}(F(\alpha)) = \alpha \), and for all ordinals \( \alpha < \beta \in \mathord{height}(\mathcal{T}) \), \( F(\alpha) \mathord{<_T} F(\beta) \). Moreover, for each ordinal \( \alpha \in \mathord{height}(\mathcal{T}) \), we define

\[
\mathcal{T}_\alpha = \{ f \in \mathcal{T} \mid \mathord{height}(f) < \alpha \}.
\]

**Proposition 5.1.** GBC + “Ord is weakly compact” \( \vdash \) Global Choice, where

Global Choice \( \exists F, ((F : V \setminus \{ \varnothing \} \to V) \land \forall x \in V \setminus \{ \varnothing \}. F(x)(x) = x) \).

**Proof-sketch.** Consider the class tree of well-ordenerings of \( V_\alpha \), for all ordinals \( \alpha \): The well-orderings are ordered by \( P \leq Q \iff P = Q \!estriction_{\mathord{dom}(P)} \). Using “Ord is weakly compact”, one can show that this tree has a branch. From this branch a class-function witnessing global choice can be constructed. \( \square \)

In [Enayat, 2004] it is shown that the \( \mathcal{L}^0 \)-consequences of GBC + “Ord is weakly compact” are the same as for ZFC + \( \Phi \), where

\[
\Phi = \{ \exists \kappa. \kappa \text{ is } n\text{-Mahlo} \land V_\kappa \prec_{\Sigma_n} V \mid n \in \mathbb{N} \}.
\]

In particular, they are equiconsistent. Let us therefore define \( n\text{-Mahlo} \) and explain why \( V_\kappa \prec_{\Sigma_n} V \) can be expressed as a sentence.

\( V_\kappa \prec_{\Sigma_n} V \) is expressed by a sentence saying that for all \( \Sigma_n \)-formulae \( \phi(x) \) of set theory and for all \( \vec{a} \in V_\kappa \) matching the length of \( \vec{x} \), we have \( ((V_\kappa, \in, \bar{V}) \models \phi(\vec{a})) \iff \text{Sat}_{\Sigma_n}(\phi, \vec{a}) \). Here we utilize the partial satisfaction relations \( \text{Sat}_{\Sigma_n} \), introduced to set theory in [Levy, 1965].

In contrast to the result above, Enayat has communicated to the author that there are countable models of ZFC + \( \Phi \) that do not expand to models of GBC + “Ord is weakly compact”. In particular, such is the fate of Paris models, i.e. models of ZFC each of whose ordinals is definable in the model. An outline of a proof: Let \( \mathcal{M} \) be a Paris model. There is no ordinal \( \alpha \) in \( \mathcal{M} \), such that \( \mathcal{M}_\alpha \prec \mathcal{M} \), where \( \mathcal{M}_\alpha = \{ (V_{\alpha}^M)^M, \epsilon_M^M \restriction (V_{\alpha}^M)^M \} \), because that would entail that a correct satisfaction relation is definable in \( \mathcal{M} \) contradicting Tarski’s well-known theorem on the undefinability of truth. Suppose that \( \mathcal{M} \) expands to a model \( (\mathcal{M}, \mathcal{A}) \models GBC + \text{“Ord is weakly compact”} \). Then by the proof of Theorem 4.5(i) in [Enayat, 2001], \( \mathcal{M} \) has a safe satisfaction relation \( \text{Sat} \in \mathcal{A} \) (see the definition preceding Lemma 6.14 below). But then there is, by Lemma 6.13 unboundedly many ordinals \( \alpha \) in \( \mathcal{M} \) such that \( \mathcal{M}_\alpha \prec \mathcal{M} \).

Moreover, it is shown in [Enayat, Hamkins, 2017] that for every model \( \mathcal{M} \models \text{ZFC} \) and the collection \( \mathcal{A} \) of definable subsets of \( \mathcal{M} \), we have \( (\mathcal{M}, \mathcal{A}) \models \text{GBC} + \neg \text{“Ord is weakly compact”} \).
6 Non-standard models of set theory

This section contains basic material on non-standard models of set theory. An expanded version of this section with more proofs is found as §4.6 of [Gorbow, 2018].

If $\mathcal{M}$ is an $\mathcal{L}^0$-structure, and $a$ is a set or class in $\mathcal{M}$, then the externalization of $a$, denoted $a_{\mathcal{M}}$, is defined as $\{x \in \mathcal{M} \mid x \in^\mathcal{M} a\}$. If $E = \in^\mathcal{M}$, then the notation $a_E$ is also used for $a_{\mathcal{M}}$. If $f \in \mathcal{M}$ and $\mathcal{M} \models "f \text{ is a function}"$, then we say that $f$ is a function internal to $\mathcal{M}$. If $f \in \mathcal{M}$ is a function internal to $\mathcal{M}$, then $f_\mathcal{M}$ also denotes the externalization of this function: $\forall x,y \in \mathcal{M}. (f_\mathcal{M}(x) = y \iff \mathcal{M} \models f(x) = y)$. Moreover, if $a \in \mathcal{M}$ codes a structure internal to $\mathcal{M}$, then $a_{\mathcal{M}}$ also denotes the externalization of this structure; in particular, if $R$ codes a relation in $\mathcal{M}$, then $\forall x,y \in \mathcal{M}. (xR_\mathcal{M}y \iff \mathcal{M} \models \langle x, y \rangle \in R)$. For example, recall that $\mathbb{N}^{\mathcal{M}}$ denotes the interpretation of $\mathbb{N}$ in $\mathcal{M}$ (assuming that $\mathcal{M}$ satisfies that the standard model of arithmetic exists); then $\mathbb{N}^{\mathcal{M}}_{\mathcal{M}}$ denotes the externalization of this model (which might be non-standard).

Let $\mathcal{M} \models \text{KP}$. Then every element of $\mathcal{M}$ has a rank; so for any $\alpha \in \text{Ord}^{\mathcal{M}}$, we can define

$$\mathcal{M}_\alpha = \{m \in \mathcal{M} \mid \mathcal{M} \models \text{rank}(m) < \alpha\}.$$ 

We say that an embedding $i : S \to \mathcal{M}$ of an $\mathcal{L}^0$-structure $S$ into $\mathcal{M}$ is bounded (by $\alpha \in \text{Ord}^{\mathcal{M}}$) if $i(S) \subseteq \mathcal{M}_\alpha$.

**Definition 6.1.** Let $\mathcal{M} = (M, E)$ be a model in $\mathcal{L}^0$. It is standard if $E$ is well-founded. Assume that $\mathcal{M}$ is a model of KP. Then the usual rank-function rank : $M \to \text{Ord}^{\mathcal{M}}$ is definable in $\mathcal{M}$. Therefore $\mathcal{M}$ is non-standard iff $E \models \text{Ord}^{\mathcal{M}}$ is not well-founded. $m \in \mathcal{M}$ is standard in $\mathcal{M}$ if $\mathcal{M} \models \text{rank}(m)$ is standard.

• The ordinal standard part of $\mathcal{M}$, denoted $\text{OSP}(\mathcal{M})$, is defined:

$$\text{OSP}(\mathcal{M}) = \{\alpha \in M \mid \text{"\alpha is a standard ordinal of } \mathcal{M}"\}.$$ 

We say that $\mathcal{M}$ is $\omega$-non-standard if $\text{OSP}(\mathcal{M}) = \omega$.

• The well-founded part of $\mathcal{M}$, denoted $\text{WFP}(\mathcal{M})$, is the substructure of $\mathcal{M}$ on the elements of standard rank:

$$\text{WFP}(\mathcal{M}) = \{x \in M \mid \text{"x is standard in } \mathcal{M}"\}.$$ 

• A set of the form $c_E \cap A$, where $c \in M$ and $A \subseteq M$, is said to be a subset of $A$ coded in $\mathcal{M}$. This notion is extended in the natural way to arbitrary injections into $M$. We define:

$$\text{Cod}_{\mathcal{A}}(\mathcal{M}) = \{c_E \cap A \mid c \in M\}.$$ 

• The standard system of $\mathcal{M}$ over $A \subseteq \mathcal{M}$, denoted $\text{SSy}_{\mathcal{A}}(\mathcal{M})$, is obtained by expanding $\mathcal{M} \models A$ to an $\mathcal{L}^1$-structure, adding $\text{Cod}_{\mathcal{A}}(\mathcal{M})$ as classes:

$$\text{SSy}_{\mathcal{A}}(\mathcal{M}) = \{\mathcal{M} \models A, \text{Cod}_{\mathcal{A}}(\mathcal{M})\},$$

for any $x \in A$, $c \in \mathcal{M}$ and $C \in \text{Cod}_{\mathcal{A}}(\mathcal{M})$, such that $C = c_E \cap A$. Moreover, we define

$$\text{SSy}(\mathcal{M}) = \text{SSy}_{\text{WFP}(\mathcal{M})}(\mathcal{M}).$$

**Definition 6.2.** Let $i : \mathcal{M} \to \mathcal{N}$ be an embedding of models of KP.
• *$i$* is initial, if
\[
\forall m \in \mathcal{M}, \forall n \in \mathcal{N}. \ (n \in \mathcal{N} \ i(m) \to n \in i(\mathcal{M})).
\]
This is equivalent to:
\[
\forall m \in \mathcal{M}. \ i(m, \mathcal{M}) = i(m, \mathcal{N}).
\]
• *$i$* is $\mathcal{P}$-initial (or power-initial), if it is initial and powerset preserving in the sense:
\[
\forall m \in \mathcal{M}. \forall n \in \mathcal{N}. \ (n \subseteq \mathcal{N} \ i(m) \to n \in i(\mathcal{M})).
\]
• *$i$* is rank-initial, if
\[
\forall m \in \mathcal{M}, \forall n \in \mathcal{N}. \ (\text{rank}^\mathcal{N}(n) \leq \text{rank}^\mathcal{N}(i(m)) \to n \in i(\mathcal{M})).
\]
• *$i$* is topless, if it is bounded and
\[
\forall \beta \in \text{Ord}^\mathcal{N} \setminus i(\mathcal{M}). \exists \beta' \in \text{Ord}^\mathcal{N} \setminus i(\mathcal{M}). \beta' <^\mathcal{N} \beta.
\]
• *$i$* is strongly topless, if it is bounded and for each $f \in \mathcal{N}$ with $\alpha, \beta \in \text{Ord}^\mathcal{N}$ satisfying
\[
(N \models f : \alpha \to \beta) \land \alpha_N \supseteq i(\text{Ord}^\mathcal{M}),
\]
there is $\nu \in \text{Ord}^\mathcal{N} \setminus i(\mathcal{M})$ such that for all $\xi \in i(\text{Ord}^\mathcal{M})$,
\[
f_N(\xi) \notin i(\mathcal{M}) \iff N \models f(\xi) > \nu.
\]
• *$i$* is $\omega$-topless, if it is bounded and not $\omega$-coded from above, meaning that for each $f \in \mathcal{N}$ with $\alpha, \beta \in \text{Ord}^\mathcal{N}$ satisfying
\[
(N \models f : \alpha \to \beta) \land \alpha_N \supseteq \omega \land \forall k < \omega. f_N(k) \in \text{Ord}^\mathcal{N} \setminus i(\mathcal{M}),
\]
there is $\nu \in \text{Ord}^\mathcal{N} \setminus i(\mathcal{M})$ such that $\nu <^\mathcal{N} f_N(k)$, for all $k < \omega$.

The notions of initiality are often combined with some notion of toplessness, yielding notions of cut. In particular, an embedding $i$ is a rank-cut if it is topless and rank-initial, and $i$ is a strong rank-cut if it is strongly topless and rank-initial.

It is easily seen that if $i$ is rank-initial and proper, then it is bounded, so the first condition of toplessness is satisfied. Moreover, we immediately obtain the following implications:

\[
i \text{ is initial } \iff i \text{ is } \mathcal{P}\text{-initial } \iff i \text{ is rank-initial},
\]
\[
i \text{ is topless } \iff i \text{ is } \omega\text{-topless } \iff i \text{ is strongly topless}.
\]

Proofs of the following results are found in §4.6 of [Gorbow, 2018].

**Lemma 6.3** ($\Sigma^T_n$-Overspill). Let $n \in \mathbb{N}$ and suppose that $S$ is a rank-cut of $\mathcal{M} \models \text{KP}^T + \Pi^T_n$-Foundation, that $m \in \mathcal{M}$, and that $\sigma(x, y) \in \Sigma^T_n[x, y]$. If for every ordinal $\xi \in S$, there is an ordinal $\zeta <^\mathcal{M} \xi \in S$ such that $\mathcal{M} \models \sigma(\zeta, m)$, then for every ordinal $\nu \in \mathcal{M} \setminus S$ there is an ordinal $\mu >^\mathcal{M} \mu \in \mathcal{M} \setminus S$, such that $\mathcal{M} \models \sigma(\mu, m)$.

**Proposition 6.4.** Let $\mathcal{M} \models \text{KP}^T$ and suppose that $i : \mathcal{M} \to \mathcal{N}$ is an elementary embedding. Then $i$ is initial if, and only if, it is rank-initial.
Proposition 6.5. Let $\mathcal{M} \models KP$. An element $m_0 \in \mathcal{M}$ is standard iff $\text{rank}^\mathcal{M}(m_0)$ is standard. If $\mathcal{M}$ is non-standard, then WFP($\mathcal{M}$) is a rank-cut of $\mathcal{M}$.

Proposition 6.6. Let $i : \mathcal{M} \to \mathcal{N}$ and $j : \mathcal{N} \to \mathcal{O}$ be embeddings of models of KP.

(a) If $i$ is topless and $j$ is initial, then $j \circ i : \mathcal{M} \to \mathcal{O}$ is topless.

(b) If $i$ is strongly topless and $j$ is rank-initial, then $j \circ i : \mathcal{M} \to \mathcal{O}$ is strongly topless.

Proof. Let $\gamma \in \text{Ord}(\mathcal{O}) \setminus j \circ i(\mathcal{M})$. By toplessness, there are $\beta' \prec^\mathcal{N} \beta \in \text{Ord}(\mathcal{N}) \setminus i(\mathcal{M})$. If $j(\beta') \prec^\mathcal{O} \gamma$, then we are done. Otherwise, $\gamma \not\prec^\mathcal{O} j(\beta)$, so that by initiality $\gamma \in j(\mathcal{N})$. By toplessness, this yields $\beta'' \in \text{Ord}^\mathcal{N} \setminus i(\mathcal{M})$ such that $j(\beta'') < \gamma$.

Let $f \in \mathcal{O}$ with $\alpha, \beta \in \text{Ord}(\mathcal{O})$ satisfying

$$(\mathcal{O} \models f : \alpha \to \beta) \land \alpha \mathcal{O} \supseteq (j \circ i)(\text{Ord}(\mathcal{M})).$$

By toplessness of $i$ and initiality of $j$, there is $\gamma \in \text{Ord}(\mathcal{N})$, such that $\gamma \mathcal{N} \supseteq i(\text{Ord}(\mathcal{M}))$ and $j(\gamma) \prec^\mathcal{O} \alpha$. In $\mathcal{O}$, let $f' : j(\gamma) \to j(\gamma)$ be the “truncation” of $f$ defined by $f'(\xi) = f(\xi)$, if $f(\xi) < j(\gamma)$, and by $f'(\xi) = 0$, if $f(\xi) \geq j(\gamma)$. Note that $\mathcal{O} \models \text{rank}(f') \leq j(\gamma) + 2$. So by rank-initiality, there is $g' \in \mathcal{N}$, such that $j(g') = f'$. Consequently, $\mathcal{N} \models g' : \gamma \to \gamma$, and by initiality of $j$, $(j(g'))\mathcal{O} = f'_\mathcal{O}$.

By strong toplessness of $i$, there is $\nu \in \text{Ord}^\mathcal{N} \setminus i(\mathcal{M})$ such that for all $\xi \in i(\text{Ord}(\mathcal{M}))$,

$$g'_N(\xi) \notin i(\mathcal{M}) \Leftrightarrow \mathcal{N} \models g'(\xi) > \nu.$$ 

It follows that for all $\xi \in (j \circ i)(\text{Ord}(\mathcal{M}))$,

$$(j \circ i)(\mathcal{M}) \models f(\xi) > j(\nu).$$

So $j \circ i$ is strongly topless. \qed

Lemma 6.7. Let $\mathcal{M} \models KP^\omega$ be $\omega$-non-standard and let $\alpha_0 \in \text{Ord}(\mathcal{M})$. For each $k < \omega$, let $\alpha_k \in \text{Ord}(\mathcal{M})$ such that $\mathcal{M} \models \alpha_k = \alpha_0 + k^{\mathcal{M}}$. Then $\bigcup_{k < \omega} \mathcal{M}_{\alpha_k}$ is an $\omega$-topless rank-initial substructure of $\mathcal{M}$.

Proof. $\bigcup_{k < \omega} \mathcal{M}_{\alpha_k}$ is obviously rank-initial in $\mathcal{M}$. Let $m \in \mathcal{M} \omega^\mathcal{M}$ be non-standard. Since $\alpha_0 +^\mathcal{M} m \in \mathcal{M}$, we have that $\bigcup_{k < \omega} \mathcal{M}_{\alpha_k}$ is bounded in $\mathcal{M}$. Moreover, $\bigcup_{k < \omega} \mathcal{M}_{\alpha_k}$ is topless, because otherwise $\gamma = \sup\{\alpha_k \mid k < \omega\}$ exists in $\mathcal{M}$ and $\mathcal{M} \models \gamma - \alpha_0 = \omega$, which contradicts that $\mathcal{M}$ is $\omega$-non-standard.

Let $f : \alpha \to \beta$ be a function in $\mathcal{M}$, where $\alpha, \beta \in \text{Ord}(\mathcal{M})$ and

$$\alpha_{\mathcal{M}} \supseteq \omega \land \forall k < \omega. f_M(k) \in \text{Ord}(\mathcal{M}) \setminus \bigcup_{k < \omega} \mathcal{M}_{\alpha_k}.$$ 

Note that for all $k < \omega$, $\mathcal{M} \models \forall \xi \leq k. f(\xi) > \alpha_0 + \xi$.

So by $\Delta^0_\omega$-Overspill, there is a non-standard $k \in \mathcal{M} \omega^\mathcal{M}$, such that

$$\mathcal{M} \models \forall \xi \leq k. f(\xi) > \alpha_0 + \xi.$$ 

Hence, $\alpha_0 +^\mathcal{M} k$ witnesses $\omega$-toplessness of $\bigcup_{k < \omega} \mathcal{M}_{\alpha_k}$. \qed

The following classic result is proved as Theorem 6.15 in Jech, 2002.
Theorem 6.8 (Mostowski’s Collapse). If $M$ is a well-founded model of Extensionality, then there is a unique isomorphism $\text{Mos}: M \to (T, \in |_T)$, such that $T$ is transitive. Moreover,

$$\forall x \in M. \text{Mos}(x) = \{ \text{Mos}(u) \mid u \in M, x \}.$$ 

This theorem motivates the following simplifying assumption:

**Assumption 6.9.** Every well-founded $L^0$-model $M$ of Extensionality is a transitive set, or more precisely, is of the form $(T, \in |_T)$ where $T$ is transitive and unique. Every embedding between well-founded $L^0$-models of Extensionality is an inclusion function.

In particular, for any model $M$ of KP, $\text{WFP}(M)$ is a transitive set and $\text{OSP}(M)$ is an ordinal.

**Proposition 6.10.** If $i: M \to N$ is an initial embedding between models of KP, then:

(a) $i(x) = x$, for all $x \in \text{WFP}(M)$.

(b) $i$ is $\Delta_0$-elementary. More sharply, for every $\sigma(\bar{x}) \in \Sigma_1[\bar{x}]$, and for every $\bar{a} \in M$,

$$M \models \sigma(\bar{a}) \implies N \models \sigma(i(\bar{a})).$$

(c) If $i$ is $\mathcal{P}$-initial, then it is $\Delta_0^\mathcal{P}$-elementary. More sharply, for every $\sigma(\bar{x}) \in \Sigma_1^\mathcal{P}[\bar{x}]$, and for every $\bar{a} \in M$,

$$M \models \sigma(\bar{a}) \implies N \models \sigma(i(\bar{a})).$$

(d) If $i$ is rank-initial and $\mathbb{S}$ is a common bounded substructure of $M$ and $N$, pointwise fixed by $i$, then $\text{SSy}_\mathbb{S}(M) = \text{SSy}_\mathbb{S}(N)$.

The proof is routine.

**Corollary 6.11.** If $i: M \to N$ is an embedding between models of $\text{KP}^\mathcal{P}$, then the following are equivalent:

(a) $i$ is rank-initial.

(b) $i$ is $\mathcal{P}$-initial.

(c) $i$ is initial, and for each ordinal $\xi$ in $M$, $i(V^{M}_\xi) = V^{M}_{i(\xi)}$.

*Proof.* (a) $\implies$ (b) is immediate from the definition.

(b) $\implies$ (c): The formula $x = V_\alpha$ is $\Sigma_1^\mathcal{P}$, so by Proposition 6.10, $i(V_\alpha^M) = V_\alpha^N$, for all ordinals $\alpha$ in $M$.

(c) $\implies$ (a): Let $a \in M$ with $M$-rank $\alpha$, let $b = i(a)$ with $N$-rank $\beta$, and let $c \in N$ be of $N$-rank $\gamma \leq N \beta$. Since $i$ is an embedding preserving $(\xi \mapsto V_\xi)$, we have that $b \in N, i(V_{\alpha+1})$ and $i(V_{\alpha+1}) = V_\beta$, for some $\beta' > N \beta$. Therefore $c \in i(V_{\alpha+1})$, so since $i$ is initial, we get that $c \in i(M)$. \hfill $\square$

We shall now introduce partial satisfaction relations for the Takahashi hierarchy. The details of this are worked out in §4.4 of [Gorbow, 2018]. Recall that we have assumed that each $L^0$-formula is identical to its G"odel code. Moreover, recall that for each $n \in \mathbb{N}$, $\Sigma_n^\mathcal{P}$ and $\Pi_n^\mathcal{P}$ are defined recursively by: $\Delta_0^\mathcal{P} = \Sigma_0^\mathcal{P} = \Pi_0^\mathcal{P}$ is the set of $L^0$-formulae such that every quantifier is of the form ‘$\exists x \in y$, ‘$\exists x \subseteq y$’, ‘$\forall x \in y$’ or ‘$\forall x \subseteq y$’; if $\phi$ is $\Sigma_n^\mathcal{P}$, then $\exists x. \phi$ is $\Sigma_{n+1}^\mathcal{P}$ and $\forall x. \phi$ is $\Pi_{n+1}^\mathcal{P}$; and dually, if $\phi$ is $\Pi_n^\mathcal{P}$, then $\exists x. \phi$ is $\Sigma_{n+1}^\mathcal{P}$ and $\forall x. \phi$ is $\Pi_{n+1}^\mathcal{P}$.
Theorem 6.12. For each \( n \in \mathbb{N} \), there are formulae \( \text{Sat}_{\Sigma^P_n}(\sigma, \bar{x}) \in \hat{\Sigma}^P_{\text{max}(1,n)} \) and \( \text{Sat}_{\Pi^P_n}(\pi, \bar{x}) \in \hat{\Pi}^P_{\text{max}(1,n)} \), such that for any model \( M \models \text{KP}^P \), any \( \sigma \in \hat{\Sigma}^P_n[\bar{u}] \) and any \( \pi \in \hat{\Pi}^P_n[\bar{u}] \),

\[
M \models \sigma(\bar{x}) \leftrightarrow \text{Sat}_{\Sigma^P_n}(\sigma, \bar{x}) \\
M \models \pi(\bar{x}) \leftrightarrow \text{Sat}_{\Pi^P_n}(\pi, \bar{x}).
\]

We write \( \text{Sat}_{\Delta^P_n} \) for \( \text{Sat}_{\Sigma^P_n} \) and \( \text{Sat}_{\Pi^P_n} \), as they are equivalent. By the theorem, \( \text{Sat}_{\Delta^P_n} \in \Delta^P_1 \).

Lemma 6.13. Let \( n \in \mathbb{N} \), suppose that \( M \models \text{KP}^P + \Sigma^P_n\)-Separation is non-standard, and let \( S \) be a bounded substructure of \( M \). For each \( \bar{a} \in M \), we have that \( \text{tp}_{\Sigma^P_n,S}(\bar{a}) \) and \( \text{tp}_{\hat{\Pi}^P_n,S}(\bar{a}) \) are coded in \( M \).

Proof. Let \( \alpha \) be an ordinal in \( M \), such that \( S \subseteq M_\alpha \). Note that if \( n = 0 \), then \( M \models \Delta^P_1\)-Separation, and for any \( n \in \mathbb{N} \) we have both \( \Sigma^P_n\)-Separation and \( \Pi^P_n\)-Separation in \( M \). So by Theorem 6.12 we have these sets in \( M \):

\[
s = \{ \phi(\bar{x}, \bar{v}) \mid \text{rank}(\bar{v}) < \alpha \land \text{Sat}_{\Sigma^P_n}(\phi(\bar{x}, \bar{y}), \bar{a}, \bar{v})) \}^M, \\
p = \{ \phi(\bar{x}, \bar{v}) \mid \text{rank}(\bar{v}) < \alpha \land \text{Sat}_{\Pi^P_n}(\phi(\bar{x}, \bar{y}), \bar{a}, \bar{v})) \}^M.
\]

By Theorem 6.12 \( s \) codes \( \text{tp}_{\Sigma^P_n,S}(\bar{a}) \), and \( p \) codes \( \text{tp}_{\Pi^P_n,S}(\bar{a}) \).

Theorem 6.13 below characterizing recursively saturated models of ZF is useful. To state it we introduce this definition: Let \( L^0_{\text{Sat}} \) be the language obtained by adding a new binary predicate \( \text{Sat} \) to \( L^0 \). We say that \( M \) admits a safe satisfaction relation if \( M \) expands to an \( L^0_{\text{Sat}} \)-structure \( (M, \text{Sat}^M) \), such that

(i) \( (M, \text{Sat}^M) \models ZF(L^0_{\text{Sat}}) \).

(ii) For each \( n \in \mathbb{N} \):

\[
(M, \text{Sat}^M) \models \forall \sigma \in \hat{\Sigma}_n. (\text{Sat}(\sigma, x) \leftrightarrow \text{Sat}_{\Sigma_n}(\sigma, x)) \\
(M, \text{Sat}^M) \models \forall \pi \in \hat{\Pi}_n. (\text{Sat}(\pi, x) \leftrightarrow \text{Sat}_{\Pi_n}(\pi, x))
\]

We say that \( \text{Sat}^M \) is a safe satisfaction relation on \( M \). For the second condition considered alone, we say that \( \text{Sat}^M \) is correct for standard formulae.

The following result is found as Theorem 3.2 (and the remark preceding it) in Schlipf, 1978.

Theorem 6.14. Let \( M \) be a model of ZF that admits a safe satisfaction relation. There are unboundedly many \( \alpha \in \text{Ord}^M \), such that \( M_\alpha \preceq M \).

The forward direction of the following result follows from Theorems 1.3 and 3.4 in Schlipf, 1978. The converse is easier; it follows by overspill from the observation that a model of ZF with a safe satisfaction relation codes any recursive type.

Theorem 6.15. Let \( M \models ZF \) be countable. The following conditions are equivalent:

(a) \( M \) is recursively saturated.

(b) \( M \) is \( \omega \)-non-standard and admits a safe satisfaction relation.

Moreover, even if \( M \) is not assumed countable, we have \( (a) \Rightarrow (b) \).
Definition 6.16. Let $i : \mathcal{M} \to \mathcal{M}$ be a self-embedding of a model $\mathcal{M}$ of KP.

- $x \in \mathcal{M}$ is a fixed point of $i$, if $i(x) = x$. The substructure of $\mathcal{M}$ of fixed points of $i$ is denoted $\text{Fix}(i)$.
- $X \subseteq \mathcal{M}$ is pointwise fixed by $i$, if every $x \in X$ is fixed by $i$. $x \in \mathcal{M}$ is pointwise fixed by $i$ (or an initial fixed point of $i$), if $x_{\mathcal{M}}$ is pointwise fixed by $i$. The substructure of $\mathcal{M}$ of elements pointwise fixed by $i$, is denoted $\text{Fix}_{\text{initial}}(i)$.
- $x \in \mathcal{M}$ is a rank-initial fixed point of $\mathcal{M}$, if $\{y \in \mathcal{M} \mid \text{rank}(y) \leq \text{rank}(x)\}$ is pointwise fixed by $i$. The substructure of $\mathcal{M}$ of rank-initial fixed points of $i$ is denoted $\text{Fix}_{\text{rank}}(i)$.

We say that $i$ is contractive on $A \subseteq \mathcal{M}$ if for all $x \in A$, we have $\mathcal{M} \models \text{rank}(i(x)) < \text{rank}(x)$.

Assume that $\mathcal{M}$ is extensional and $i : \mathcal{M} \to \mathcal{M}$ is initial. Then $x \in \mathcal{M}$ is a fixed point of $i$ if it is pointwise fixed by $i$. It follows that

$$\text{Fix}(i) \supseteq \text{Fix}_{\text{initial}}(i) \supseteq \text{Fix}_{\text{rank}}(i).$$

Lemma 6.17. Suppose that $\mathcal{M} \models \text{KP}_{\mathcal{P}}$ and that $i$ is a rank-initial self-embedding of $\mathcal{M}$ such that $\mathcal{S} = \mathcal{M} \upharpoonright \text{Fix}(i)$ is a rank-initial substructure of $\mathcal{M}$. Then $\mathcal{S} \preceq \mathcal{M}$.

Proof. We verify $\mathcal{S} \preceq \mathcal{M}$ using the Tarski-Vaught Test (it applies since $\Sigma^\mathcal{P}_1$ is closed under subformulae). Let $\delta(x, \vec{y}) \in \Delta^\mathcal{P}_0[x, \vec{y}]$, let $\vec{s} \in \mathcal{S}$, and assume that $\mathcal{M} \models \exists x. \delta(x, \vec{s})$. We shall now work in $\mathcal{M}$: Let $\xi$ be the least ordinal such that $\exists x \in V_{\xi+1}. \delta(x, \vec{s})$. We shall show that $i(\xi) = \xi$. Suppose not, then either $i(\xi) < \xi$ or $i(\xi) > \xi$. If $i(\xi) < \xi$, then $\exists x \in V_{i(\xi)+1}. \delta(x, \vec{s})$, contradicting that $\xi$ is the least ordinal with this property. If $i(\xi) > \xi$, then by rank-initiality there is an ordinal $\zeta < \xi$ such that $i(\zeta) = \xi$. But then $\exists x \in V_{\zeta+1}. \delta(x, \vec{s})$, again contradicting that $\xi$ is the least ordinal with this property.

By $\Delta^\mathcal{P}_0$-Separation in $\mathcal{M}$, let $D = \{x \in V_{\xi+1} \mid \delta(x, \vec{s})\}^{\mathcal{M}}$. Since $i$ is $\Delta^\mathcal{P}_0$-elementary and $\xi, \vec{s} \in \text{Fix}(i)$, we have

$$\mathcal{M} \models \{(\text{rank}(x) = \xi \land \delta(x, \vec{s})) \leftrightarrow (\text{rank}(i(x)) = \xi \land \delta(i(x), \vec{s}))\}.$$  

It immediately follows that $i(D) \subseteq D$. But by rank-initiality, every $x$ of rank $\xi$ in $\mathcal{M}$ is a value of $i$, so we even get that $i(D) = D$. Let $d \in D$. By initiality and $D \subseteq \text{Fix}(i)$, we have $d \in \text{Fix}(i)$; and by construction of $D$, $\mathcal{M} \models \delta(d, \vec{s})$, as desired.

Lemma 6.18. Suppose that $\mathcal{M} \models \text{KP}_{\mathcal{P}}$ has definable Skolem functions and that $i$ is an automorphism of $\mathcal{M}$ such that $\mathcal{S} = \mathcal{M} \upharpoonright \text{Fix}(i)$. Then $\mathcal{S} \preceq \mathcal{M}$.

Proof. Again, we apply The Tarski Test. Let $\phi(x, \vec{y}) \in \mathcal{L}^0$, let $\vec{s} \in \mathcal{S}$, and assume that $\mathcal{M} \models \exists x. \phi(x, \vec{s})$. Let $m \in \mathcal{M}$ be a witness of this fact. Let $f$ be a Skolem function for $\phi(x, \vec{y})$, defined in $\mathcal{M}$ by a formula $\psi(x, \vec{y})$. Then $\mathcal{M} \models \psi(m, \vec{s})$, and since $i$ is an automorphism fixing $\mathcal{S}$ pointwise, $\mathcal{M} \models \psi(i(m), \vec{s})$. But $\mathcal{M}$ defines a function, so $\mathcal{M} \models m = i(m)$, whence $m \in \mathcal{S}$ as desired.

7 Embeddings between models of set theory

In §4 of [Friedman, 1973], a back-and-forth technique was pioneered that utilizes partial satisfaction relations and the ability of non-standard models to code types over themselves (as indicated in Lemma 6.13). Here we will prove refinements of set theoretic results in §4 of [Friedman, 1973], as well as generalizations of arithmetic results in [Bahrani, Enayat, 2018] and [Ressayre, 1987b] to set theory. We will do so by casting the results in the conceptual framework of forcing. We do so because:
The conceptual framework of forcing allows a modular design of the proofs, clarifying which assumptions are needed for what, and whereby new pieces can be added to a proof without having to re-write the other parts. So it serves as an efficient bookkeeping device.

It enables us to look at these results from a different angle, and potentially apply theory that has been developed for usage in forcing.

**Lemma 7.1.** Let $\mathcal{M} \models KP^p + \Sigma^1_0$-Separation and $\mathcal{N} \models KP^p$ be countable and non-standard, and let $\mathcal{S}$ be a common rank-cut of $\mathcal{M}$ and $\mathcal{N}$. Moreover, let $\mathcal{P} = [\mathcal{M} \models_{\Sigma^1_0,\mathcal{S}} \mathcal{N}_\beta]$ and let $\beta \in \text{Ord} \setminus \mathcal{S}$.

(a) If $\text{SSy}_\mathcal{S}(\mathcal{M}) \subseteq \text{SSy}_\mathcal{S}(\mathcal{N})$, then

$$c_m = \{ f \in \mathcal{P} \mid m \in \text{dom}(f) \}$$

is dense in $\mathcal{P}$, for each $m \in \mathcal{M}$.

(b) If $\text{SSy}_\mathcal{S}(\mathcal{M}) = \text{SSy}_\mathcal{S}(\mathcal{N})$, then

$$d_{m,n} = \{ f \in \mathcal{P} \mid m \in \text{dom}(f) \land (\mathcal{N} \models \text{rank}(n) \leq \text{rank}(f(m))) \rightarrow n \in \text{image}(f) \}$$

is dense in $\mathcal{P}$, for each $m \in \mathcal{M}$ and $n \in \mathcal{N}$.

(c) If $\mathcal{N} = \mathcal{M}$, then

$$e_\alpha = \{ f \in \mathcal{P} \mid \exists m \in \text{dom}(f). (f(m) \neq m \land \mathcal{M} \models \text{rank}(m) = \alpha) \}$$

is dense in $\mathcal{P}$, for each $\alpha \in \text{Ord} \setminus \mathcal{S}$.

Note that $\mathcal{N}_\beta$ is rank-initial in $\mathcal{N}$, so by absoluteness of $\Delta^0_0$-formulas over rank-initial substructures, we have for any $n \in \mathcal{N}_\beta$, for any $s \in \mathcal{S}$ and for any $\delta(x,y,z) \in \Delta^0_0[x,y,z]$, that

$$\mathcal{N} \models \exists x \in V_\beta. \delta(x,n,s) \iff \mathcal{N}_\beta \models \exists x. \delta(x,n,s). \quad (\dagger)$$

**Proof.** If $\mathcal{P} = \varnothing$, then the result is trivial, so assume that $\mathcal{P} \neq \varnothing$. This means in particular that $\text{Th}_{\Sigma^1_0,\mathcal{S}}(\mathcal{M}) \subseteq \text{Th}_{\Sigma^1_0,\mathcal{S}}(\mathcal{N}_\beta)$.

Let $g \in \mathcal{P}$. Unravel $g$ as a $\gamma$-sequence of ordered pairs $\langle m_\xi, n_\xi \rangle_{\xi < \gamma}$, where $\gamma < \omega$. Let $m_\gamma \in \mathcal{M}$ be arbitrary. We need to find $f$ in $\mathcal{P}$ extending $g$, such that $m_\gamma \in \text{dom}(f)$.

Using $\text{Sat}_{\Sigma^1_0}$, we have by Lemma 6.13 and $\Sigma^1_0$-Separation that there is a code $c$ in $\mathcal{M}$ for

$$\{ \langle \delta, s \rangle \mid \delta \in \Delta^0_0[x, \langle y_\xi \rangle_{\xi < \gamma}, y, z] \land s \in \mathcal{S} \land \mathcal{M} \models \exists x. \delta(x, \langle m_\xi \rangle_{\xi < \gamma}, m_\gamma) \}.$$  

By $\text{SSy}(\mathcal{M}) \subseteq \text{SSy}(\mathcal{N}_\beta)$, this set has a code $d$ in $\mathcal{N}_\beta$ as well. We define the formula

$$\phi(\zeta, p, \langle y_\xi \rangle_{\xi < \gamma+1}) \equiv \exists y. \forall (\delta, t) \in p \cap V_\zeta. \exists x. \text{Sat}_{\Delta^0_0}(\delta, x, \langle y_\xi \rangle_{\xi < \gamma}, y, t).$$

Since $\text{Sat}_{\Delta^0_0} \in \Delta^0_0$, we have $\phi \in \Sigma^1_0$. For every ordinal $\zeta \in \mathcal{S}$, we have $c \cap V_\zeta = d \cap V_\zeta \in \mathcal{S}$, and as witnessed by $m_\gamma$, we have $\mathcal{M} \models \phi(\zeta, c, \langle m_\xi \rangle_{\xi < \gamma})$. So by $g \in \mathcal{P}$, we have $\mathcal{N}_\beta \models \phi(\zeta, d, \langle n_\xi \rangle_{\xi < \gamma})$ for every ordinal $\zeta \in \mathcal{S}$. Since $\mathcal{S}$ is topless in $\mathcal{N}_\beta$, there is by $\Sigma^1_0$-Overspill an ordinal $\nu$ in $\mathcal{N}_\beta \setminus \mathcal{S}$, such that $\mathcal{N}_\beta \models \phi(\nu, d, \langle n_\xi \rangle_{\xi < \gamma})$. Set $m_\gamma$ to some witness of this fact.
Put \( f = g \cup \{ (m_\gamma, n_\gamma) \} \). We proceed to verify that \( f \) is \( \Sigma^P_\alpha \)-elementary. Let \( s \in \mathcal{S} \) and let \( \delta(x, \langle y_\xi \rangle_{\xi < \gamma + 1}, z) \in \Delta^P_\alpha \{ x, \langle y_\xi \rangle_{\xi < \gamma + 1}, z \} \). Now, as desired,
\[
\mathcal{M} \models \exists x. \delta(x, \langle m_\xi \rangle_{\xi < \gamma + 1}, s) \Rightarrow \langle \delta, s \rangle \in d \\
\Rightarrow \mathcal{N}_\beta \models \exists x. \delta(x, \langle n_\xi \rangle_{\xi < \gamma + 1}, s).
\]
The second implication follows from the choice of \( n_\gamma \) and Theorem 6.12.
\[\square\] Let \( g \in \mathcal{P} \). Unravel \( g \) as a \( \gamma \)-sequence of ordered pairs \( \langle m_\xi, n_\xi \rangle_{\xi < \gamma} \), where \( \gamma < \omega \). Let \( \xi_0 < \gamma \), and suppose that \( n_\gamma \in \mathcal{N}_\beta \), such that \( \mathcal{N}_\beta \models \text{rank}(n_\gamma) \leq \text{rank}(g(m_{\xi_0})) \). By (\( \blacksquare \)), it suffices to find \( f \in \mathcal{P} \) extending \( g \), such that \( n_\gamma \in \text{image}(f) \).

By \( \mathcal{N} \models \Delta_1\text{-Separation} \), (\( \blacksquare \)) and Lemma 6.13, there is a code \( d' \) in \( \mathcal{N}_\beta \) for
\[
\{ \langle \delta, s \rangle \mid \delta \in \Delta^P_\alpha \{ x, \langle y_\xi \rangle_{\xi < \gamma}, y, z \} \wedge s \in \mathcal{S} \wedge
\mathcal{N}_\beta \models \exists x. \delta(x, \langle n_\xi \rangle_{\xi < \gamma}, n_\gamma, s) \}.
\]
By SSY_\mathcal{S}(\mathcal{M}) \supseteq SSY_\mathcal{S}(\mathcal{N}) \), let \( c' \) be its code in \( \mathcal{M} \). We define the formula
\[
\psi(\zeta, p, \langle y_\xi \rangle_{\xi < \gamma}) \equiv \exists y \subseteq V_{\text{rank}(y_\upsilon)} \forall (\delta, t) \in p \cap V_\zeta. \forall x. \text{Sat}_{\Delta^P_\alpha}(\delta, x, \langle y_\xi \rangle_{\xi < \gamma}, y, t).
\]
Since \( \text{Sat}_{\Delta^P_\alpha} \) and the function \( (u \mapsto V_{\text{rank}(y_\upsilon)}) \) are \( \Delta^P_\alpha \), we have that \( \psi \) is \( \Pi^P_\alpha \). Moreover, \( d' \cap V_\zeta = c' \cap V_\zeta \). Note that for every ordinal \( \zeta \in \mathcal{S} \), we have \( \mathcal{N}_\beta \models \psi(\zeta, c', \langle n_\xi \rangle_{\xi < \gamma}) \), as witnessed by \( n_\gamma \).

It follows from \( g \in \mathcal{P} \) that \( \psi(\zeta, c', \langle m_\xi \rangle_{\xi < \gamma}) \) is satisfied in \( \mathcal{M} \) for every ordinal \( \zeta \in \mathcal{S} \), whence by \( \Pi^P_\alpha\)-Overspill we have \( \mathcal{M} \models \psi(\mu, c', \langle m_\xi \rangle_{\xi < \gamma}) \), for some ordinal \( \mu \in \mathcal{M} \setminus \mathcal{S} \). (It follows from \( \Sigma_1\text{-Separation} \), Proposition \( \blacksquare \) and Lemma \( \blacksquare \) that \( \mathcal{M} \) satisfies \( \Pi^P_\alpha\)-Overspill.) Let \( m_\gamma \) be some witness of this fact, and put \( f = g \cup \{ (m_\gamma, n_\gamma) \} \). We proceed to verify that \( f \in \mathcal{P} \). Let \( s \in \mathcal{S} \) and let \( \delta(x, \langle y_\xi \rangle_{\xi < \gamma + 1}, z) \in \Delta^P_\alpha \{ x, \langle y_\xi \rangle_{\xi < \gamma + 1}, z \} \). Now, as desired,
\[
\mathcal{N}_\beta \models \forall x. \delta(x, \langle n_\xi \rangle_{\xi < \gamma + 1}, s) \Rightarrow \langle \delta, s \rangle \in c' \\
\Rightarrow \mathcal{M} \models \forall x. \delta(x, \langle m_\xi \rangle_{\xi < \gamma + 1}, s).
\]
The second implication follows from the choice of \( m_\gamma \) and Theorem 6.12.
\[\square\] Let \( \alpha \in \text{Ord}^\mathcal{M} \setminus \mathcal{S} \), and let \( g \in \mathcal{P} \). Unravel \( g \) as a \( \gamma \)-sequence of ordered pairs \( \langle m_\xi, n_\xi \rangle_{\xi < \gamma} \), where \( \gamma < \omega \). We need to find \( m_\gamma \neq n_\gamma \), such that \( \mathcal{M} \models \text{rank}(m_\gamma) = \alpha \) and \( g \cup \{ (m_\gamma, n_\gamma) \} \in \mathcal{P} = [\mathcal{M} \rhd_{\mathcal{S}^*} \mathcal{N}_\beta] \). Note that by rank-initiality and toplessness, there is \( \alpha' \in \text{Ord}^\mathcal{M} \setminus \mathcal{S} \), such that \( (\alpha' + 3) \leq \alpha \) and \( \mathcal{M}_{\alpha'} \supseteq \mathcal{S} \).

We proceed to work in \( \mathcal{M} \): The set \( V_{\alpha + 1} \setminus V_\alpha \) of sets of rank \( \alpha \) has cardinality \( \beth_{\alpha + 1} \), while the set \( \mathcal{P}(V_\alpha \times V_\alpha) \subseteq V_{\alpha' + 3} \) is strictly smaller, of cardinality less than or equal to \( \text{card}(V_\alpha) \). (Here we used \( \mathcal{M} \models \text{Powerset} \), and the recursive definition \( \beth_0 = 0, \beth_{\xi + 1} = 2^{\beth_\xi}, \beth_\xi = \sup\{ \beth_\zeta \mid \zeta < \xi \} \) for limits \( \xi \).) We define a function \( t : V_{\alpha + 1} \setminus V_\alpha \rightarrow V_{\alpha' + 3} \) by
\[
t(v) = \{ \langle \delta, s \rangle \mid \delta \in \Delta^P_\alpha \{ x, \langle y_\xi \rangle_{\xi < \gamma}, y, z \} \wedge s \in \mathcal{S} \wedge
\exists x. \text{Sat}_{\Delta^P_\alpha}(\delta, x, \langle m_\xi \rangle_{\xi < \gamma}, v, s) \},
\]
for each \( v \in V_{\alpha + 1} \setminus V_\alpha \). \( t \) exists by \( \Sigma^P_\alpha \)-Separation. Since \( t \) has a domain of strictly larger cardinality than its co-domain, there are \( m, m' \) of rank \( \alpha \), such that \( m \neq m' \) and \( t(m) = t(m') \).

We return to working in the meta-theory: \( m \) and \( m' \) have the same \( \Sigma^P_\alpha \)-type with parameters in \( \mathcal{S} \cup \{ m_\xi \}_{\xi < \gamma} \). In other words, for every \( s \in \mathcal{S} \) and every \( \delta(x, \langle y_\xi \rangle_{\xi < \gamma}, y, z) \in \Delta^P_\alpha \{ x, \langle y_\xi \rangle_{\xi < \gamma}, y, z \} \), we have
\[
\mathcal{M} \models \exists x. \delta(x, \langle m_\xi \rangle_{\xi < \gamma}, m, s) \leftrightarrow \exists x. \delta(x, \langle m_\xi \rangle_{\xi < \gamma}, m', s).
\]
On the other hand, by (a) and by \( g \in \mathbb{P} \), there are \( n, n' \), such that for every \( s \in \mathcal{S} \) and every \( \delta(x, (y_\xi)_{\xi<\gamma}, y_\gamma, y_{\gamma+1}, z) \in \Delta^p_\mathcal{P}[x, (y_\xi)_{\xi<\gamma}, y_\gamma, y_{\gamma+1}, z] \), we have
\[
\mathcal{M} \models \exists x. \delta(x, (m_\xi)_{\xi<\gamma}, m, m', s) \iff \exists x \in V_{\beta} \delta(x, (n_\xi)_{\xi<\gamma}, n, n', s).
\]
(\( \dagger \))

By (\( \dagger \)), \( n \neq n' \), whence \( m \neq n \) or \( m \neq n' \). If \( m \neq n \), then \( g \cup \{ (m, n) \} \in \mathcal{E}_\alpha \) by (a). If \( m \neq n' \), then by (\( \dagger \)) and (\( \dagger \)),
\[
\mathcal{M} \models \exists x. \delta(x, (m_\xi)_{\xi<\gamma}, m, s) \iff \exists x \in V_{\beta} \delta(x, (n_\xi)_{\xi<\gamma}, m', s)
\Rightarrow \mathcal{M} \models \exists x \in V_{\beta} \delta(x, (n_\xi)_{\xi<\gamma}, n', s),
\]
so \( g \cup \{ (m, n') \} \in \mathcal{E}_\alpha \). In either case we are done. \( \square \)

Based on this Lemma, we can prove a theorem that refines results in §4 of [Friedman, 1973]. If \( i, j : \mathcal{M} \rightarrow \mathcal{N} \) are rank-initial embeddings between models of \( KP \), then we write \( i <_{\text{rank}} j \) to indicate that \( i|_{\text{image}(i)} \) is a rank-initial substructure of \( \mathcal{N}|_{\text{image}(i)} \).

**Theorem 7.2** (Friedman-style). Let \( \mathcal{M} \models KP + \Sigma^p_\mathcal{P} \text{-Separation} \) and \( \mathcal{N} \models KP \) be countable and non-standard, and let \( \mathcal{S} \) be a shared rank-cut of \( \mathcal{M} \) and \( \mathcal{N} \). Moreover, let \( n_0 \in \mathcal{M} \), let \( n_0 \in \mathcal{N} \), and let \( m_0 \in \mathcal{N} \). Then the following are equivalent:

(a) There is a rank-initial embedding \( i : \mathcal{M} \rightarrow \mathcal{N} \), fixing \( \mathcal{S} \) pointwise, such that \( i(n_0) = n_0 \) and \( i(\mathcal{M}) \subseteq \mathcal{N}_{\beta} \).

(b) \( \text{SSy}_\mathcal{S}(\mathcal{M}) = \text{SSy}_\mathcal{S}(\mathcal{N}) \), and for all \( s \in \mathcal{S} \) and \( \delta(x, y, z) \in \Delta^p_\mathcal{S}[x, y, z] \):
\[
\mathcal{M} \models \exists x. \delta(x, n_0, s) \Rightarrow \mathcal{N} \models \exists x \in V_{\beta} \delta(x, n_0, s).
\]

(c) There is a map \( g \mapsto i_g \), from sequences \( g : \omega \rightarrow 2 \), to embeddings \( i_g : \mathcal{M} \rightarrow \mathcal{N} \) satisfying (a), such that for any \( g <^\text{lex} g' : \omega \rightarrow 2 \), we have \( i_g <_{\text{rank}} i_{g'} \).

(d) There is a topless embedding \( i : \mathcal{M} \rightarrow \mathcal{N} \) satisfying (a).

**Proof.** Most of the work has already been done for (a) \( \iff \) (b). The other equivalences are proved as Lemma 7.3 below.

(a) \( \implies \) (b). The first conjunct follows from Proposition 6.10(c). The second conjunct follows from Proposition 6.10(d) and that \( i(\mathcal{M}) \) is rank-initial in \( \mathcal{N}_{\beta} \).

(b) \( \implies \) (a). Let \( \mathbb{P} = [\mathcal{M} \preceq_{\Sigma^p_\mathcal{S}} \mathcal{N}_{\beta}] \). By the second conjunct of (b), the function \( f_0 \) defined by \( (m_0 \mapsto n_0) \), with domain \( \{ m_0 \} \), is in \( \mathbb{P} \). Using Lemma 3.1 and Lemma 7.4 (a, b), we obtain a filter \( \mathcal{I} \) on \( \mathbb{P} \) which contains \( f_0 \) and is \( \{ \mathcal{D}_{m,n} | m \in \mathcal{M} \land n \in \mathcal{N} \} \)-generic (and hence \( \{ \mathcal{C}_m | m \in \mathcal{M} \} \)-generic as well). Let \( i = \bigcup \mathcal{I} \). Since \( \mathcal{I} \) is downwards directed, \( i \) is a function. Clearly \( \text{image}(i) \subseteq \mathcal{N}_{\beta} \). Since \( \mathcal{I} \) is \( \{ \mathcal{C}_m | m \in \mathcal{M} \} \)-generic, \( i \) has domain \( \mathcal{M} \); and since \( f_0 \in \mathcal{I} \), \( i(m_0) = n_0 \). To see that \( i \) is rank-initial, let \( m \in \mathcal{M} \), and let \( n \in \mathcal{N} \) such that \( \mathcal{N} \models \text{rank}(n) \leq \text{rank}(i(m)) \). Since \( \mathcal{I} \cap \mathcal{D}_{m,n} \neq \varnothing \), we have that \( n \) is in the image of \( i \). \( \square \)

Friedman’s theorem is especially powerful in conjunction with the following lemmata.

**Lemma 7.3.** Let \( \mathcal{N} \models KP + \Sigma^p_\mathcal{P} \text{-Separation} \), let \( n \in \mathcal{N} \) and let \( \mathcal{S} \) be a bounded substructure of \( \mathcal{N} \). Then there is an ordinal \( \beta \in \mathcal{N}_i \), such that for each \( s \in \mathcal{S} \), and for each \( \delta(x, y, z) \in \Delta^p_\mathcal{S}[x, y, z] \):
\[
(\mathcal{N}, n, s) \models (\exists x. \delta(x, n, s)) \iff (\exists x \in V_{\beta} \delta(x, n, s)).
\]
of Theorem 7.2, there is an embedding by Lemma 7.3, there is

Proof.

Lemma 7.6.

Let \( N \models \text{KP}^P + \Sigma_2^P \)-Separation, let \( n \in N \) and let \( S \) be a bounded substructure of \( N \). Then there are unboundedly many ordinals \( \beta \in N \), such that for each \( s \in S \), and for each \( \delta(x', y, z) \in \Delta_0^P[x, x', y, z] \):

\[
(N, n, s) \models (\forall x. \exists x'. \delta(x, x', n, s)) \rightarrow (\forall x \in V_{\beta}. \exists x' \in V_{\beta}, \delta(x, x', n, s)).
\]

Proof. Let \( \alpha \) be an ordinal in \( N \). Let \( \beta_0 >^N \alpha \) be an infinite ordinal in \( N \) such that \( S \subseteq N_{\beta_0} \).

We work in \( N \): By \( \Sigma_2^P \)-Recursion (which is equivalent to \( \Pi_2^P \)-Separation), let

\[
D = \{ (\delta, t) \in \Delta_0^P[x, x', y, z] \times V_{\beta_0} | (\forall x \in V_{\beta}. \exists x' \in V_{\beta}, \delta(x, x', n, s)) \}\.
\]

Recursively, for each \( k < \omega \), let \( \beta_{k+1} \) be the least ordinal such that

\[
\forall (\delta, t) \in D. (\forall x \in V_{\beta_k}. \exists x' \in V_{\beta_{k+1}}, \delta(x, x', n, s)).
\]

The existence of the set \( \{ \beta_k \mid k < \omega \} \) follows from \( \Sigma_2^P \)-Recursion, because the functional formula defining the recursive step is \( \Sigma_1^P \), as seen when written out as \( \phi(\beta_k, \beta_{k+1}) \land \forall \gamma < \beta_{k+1}, \neg \phi(\beta_k, \gamma) \), where \( \phi(\beta_k, \beta_{k+1}) \) is the formula \( \forall (\delta, t) \in D. (\forall x \in V_{\beta_k}. \exists x' \in V_{\beta_{k+1}}, \delta(x, x', n, s)) \).

Put \( \beta = \sup \{ \beta_k \mid k < \omega \} \).

Let \( s \in S \) and let \( \delta(x, x', y, z) \in \Delta_0^P[x, x', y, z] \). To verify that

\[
(N, n, s) \models (\forall x. \exists x'. \delta(x, x', n, s)) \rightarrow (\forall x \in V_{\beta}. \exists x' \in V_{\beta}, \delta(x, x', n, s)),
\]

we work in \( (N, n, s) \): Suppose that \( \forall x. \exists x'. \delta(x, x', n, s) \), and let \( x \in V_{\beta} \). Then \( x \in V_{\beta_k} \) for some \( k < \omega \). By construction, there is \( x' \in V_{\beta_{k+1}} \), such that \( \delta(x, x', n, s) \). So by the properties of \( \delta(x, x', n, s) \), we have \( \delta(x, x', n, s) \), as desired.

Lemma 7.5. Under the assumptions of Theorem 7.2, for each embedding \( i_1 : M \rightarrow N \) satisfying \( \text{(a)} \) of Theorem 7.2, there is an embedding \( i_0 <^{\text{rank}} i_1 \) satisfying \( \text{(a)} \).

Proof. By Lemma 7.3 there is \( \alpha \) Ord \(^M \), such that for all \( s \in S \) and all \( \delta(x, y, z) \in \Delta_0^P[x, y, z] \):

\[
M \models \exists x. \delta(x, m, s) \iff M \models \exists x \in V_\alpha. \delta(x, m, s).
\]

By Proposition 6.10(c) applied to \( i_1 \), we have for all \( s \in S \) and all \( \delta(x, y, z) \in \Delta_0^P[x, y, z] \) that

\[
M \models \exists x \in V_\alpha. \delta(x, m, s) \Rightarrow N \models \exists x \in V_{i_1(\alpha)}. \delta(x, n, s),
\]

and consequently that

\[
M \models \exists x. \delta(x, m, s) \Rightarrow N \models \exists x \in V_{i_1(\alpha)}. \delta(x, n, s).
\]

By Proposition 6.10(c) applied to \( i_0 \) there is a rank-initial embedding \( i_0 : M \rightarrow N \), such that \( i_0(m) = n \) and \( i_0(M) \subseteq V^N_{i_1(\alpha)} \). Since \( i_1(\alpha) \in i_1(M) \setminus i_0(M) \), we are done.

Lemma 7.6. These statements are equivalent to \( \text{(m)} \) in Theorem 7.3.

(c) There is a map \( g \mapsto i_g \), from sequences \( g : \omega \rightarrow 2 \), to embeddings \( i_g : M \rightarrow N \) satisfying \( \text{(a)} \), such that for any \( g <^{\text{lex}} g' : \omega \rightarrow 2 \), we have \( i_g <^{\text{rank}} i_{g'} \).

21
(d) There is a topless embedding $i : \mathcal{M} \to \mathcal{N}$ satisfying \(\mathbb{H}\).

Proof. It suffices to show that \(\mathbb{H} \Rightarrow \mathbb{I} \Rightarrow \mathbb{I}\).

\(\mathbb{I} \Rightarrow \mathbb{H}\): Let $(a_\xi)_{\xi < \omega}$ and $(b_\xi)_{\xi < \omega}$ be enumerations of $\mathcal{M}$ and $\mathcal{N}$, respectively, with infinitely many repetitions of each element. For each $g : \omega \to 2$, we shall construct a distinct $i_g : \mathcal{M} \to \mathcal{N}$. To do so, we first construct approximations of the $i_g$.

For any $\gamma < \omega$, we allow ourselves to denote any function $f : \gamma \to 2$ as an explicit sequence of values $f(0), f(1), \ldots, f(\gamma - 1)$. For each $\gamma < \omega$, we shall construct a finite subdomain $D_\gamma \subseteq \mathcal{M}$, and for each $f : \gamma \to 2$, we shall construct an embedding $i_f$. We do so by this recursive construction on $\gamma < \omega$:

1. For $i_\emptyset : \mathcal{M} \to \mathcal{N}$, choose any embedding satisfying \(\mathbb{H}\).

2. Put $D_\emptyset = \{m\}$.

3. Suppose that $i_f$ has been constructed for some $f : \gamma \to 2$, where $\gamma < \omega$. Put $i_{f,1} = i_f$.

Applying Lemma 7.5 to $i_{f,1}$, with $D_\gamma$ in place of $m$ and with $i_f(D_\gamma)$ in place of $n$, we choose an embedding $i_{f,0} : \mathcal{M} \to \mathcal{N}$ such that:

   (i) $i_{f,0}, i_{f,1}$ are rank-initial, with all values of rank below $\beta$ in $\mathcal{N}$;

   (ii) $i_{f,0} \upharpoonright D_\gamma = i_{f,1} \upharpoonright D_\gamma = i_f \upharpoonright D_\gamma$;

   (iii) $i_{f,0} < \text{rank } i_{f,1}$.

4. Put $D_{\gamma+1}$ to be a finite subdomain of $\mathcal{M}$, such that:

   (i) $D_\gamma \subseteq D_{\gamma+1}$;

   (ii) $a_\gamma \in D_{\gamma+1}$;

   (iii) For each $f : \gamma + 1 \to 2$, if $(\text{rank}(b_\gamma) \leq \sup(\text{rank}(i_f(a)) \mid a \in D_\gamma)) \subseteq N$, then $i_f^{-1}(b_\gamma) \in D_{\gamma+1}$ (note that $i_f^{-1}(b_\gamma)$ exists by rank-initiality of $i_f$);

   (iv) For each $f : \gamma \to 2$, we have that $i_{f,1}^{-1}(\nu) \in D_{\gamma+1}$, for some $\nu \in i_{f,1}(\text{Ord}^M) \setminus i_{f,0}(\text{Ord}^M)$.

Note that every $a \in \mathcal{M}$ is in $D_\gamma$ for some $\gamma < \omega$. Moreover, for every $\gamma < \omega$, if $f < \text{lex } f' : \gamma \to 2$, then $i_f < \text{rank } i_{f'}$.

Now, for each $g : \omega \to 2$, define $i_g : \mathcal{M} \to \mathcal{N}$ by

$$i_g(a) = i_g|_\gamma(a),$$

for each $a \in \mathcal{M}$, where $\gamma < \omega$ is such that $a \in D_\gamma$. Note that for each $\gamma < \omega$, $i_g \upharpoonright D_\gamma = i_g|_\gamma$. We now verify that these $i_g$ have the desired properties. Let $g : \omega \to 2$.

- $i_g$ is an embedding: Let $\phi(x)$ be a quantifier free formula and let $a \in \mathcal{M}$. Then $a \in D_\gamma$ for some $\gamma < \omega$, so since $i_g|_\gamma$ is an embedding, $\mathcal{M} \models \phi(a) \Rightarrow \mathcal{N} \models \phi(i_g(a))$.

- $i_g(m) = n$: $m \in D_\emptyset$ and $i_g \upharpoonright D_\emptyset = i_\emptyset \upharpoonright D_\emptyset$.

- $i_g(\mathcal{M}) \subseteq \mathcal{N}_\beta$: Let $a \in \mathcal{M}$ and pick $\gamma < \omega$ such that $a \in D_\gamma$. Then $i_g(a) = i_g|_\gamma(a) \in \mathcal{N}_\gamma$.

- $i_g$ is rank-initial: Let $a \in \mathcal{M}$ and $b \in \mathcal{N}$, such that $\mathcal{N} \models \text{rank}(b) \leq \text{rank}(i_g(a))$. Pick $\gamma < \omega$ such that $a \in D_\gamma$. By (iii), $i_g|_{\gamma+1}(b) \in D_{\gamma+1}$. So $b \in i_g(\mathcal{M})$. 22
• If \( g <^\text{lex} g' : \omega \to 2 \), then \( i_g <^\text{rank} i_{g'} \): Let \( \gamma < \omega \) be the least such that \( g(\gamma) < g'(\gamma) \). By (4ii), \( i_{g'} >^\text{rank} i_{g|\gamma+1} \geq^\text{rank} i_g \).

(4i) \( \Rightarrow \) (4ii): Since \( N \) is countable, there are only \( \aleph_0 \) many ordinals in \( N \) which top a substructure, so by (4i) we are done.

The following two results sharpen results in §4 of Friedman, 1973.

**Corollary 7.7.** Let \( M \models \text{KP}^+ + \Sigma_1^P\)-Separation and \( N \models \text{KP}^+ + \Sigma_1^P\)-Separation be countable and non-standard. Let \( S \) be a common rank-cut of \( M \) and \( N \). Then the following are equivalent:

(a) There is a rank-initial \( i : M \to N \), fixing \( S \) pointwise.

(a') There is a rank-cut \( i : M \to N \), fixing \( S \) pointwise.

(b) \( \text{SSy}(M) = \text{SSy}(N) \), and \( \text{Th}_{\Sigma_1^P,S}(M) \subseteq \text{Th}_{\Sigma_1^P,S}(N) \).

**Proof.** (a) \( \Rightarrow \) (b) is proved just as for Theorem 7.2.

(b) \( \Rightarrow \) (a') follows from Theorem 7.2 by letting \( \beta \in N \) be as obtained from Lemma 7.3, and setting \( m_0 = \varnothing^M \) and \( n_0 = \varnothing^N \).

**Theorem 7.8.** Let \( M \models \text{KP}^+ + \Sigma_1^P\)-Separation be countable and non-standard. Let \( S \) be a rank-cut of \( M \). Then there is a rank-cut \( i : M \to M \), fixing \( S \) pointwise, such that

\[ \forall \alpha \in \text{Ord}^M \setminus S. \exists m \in M. (\text{rank}^M(m) = \alpha \land i(m) \neq m). \]

**Proof.** Let \( \beta \in M \) be the ordinal bound obtained from Lemma 7.3 and let \( P = \{M <^\text{lex} \Sigma_1^P,S M\} \). Put \( m_0 = n_0 = \varnothing^M \). We adjust the proof of (11) \( \Rightarrow \) (12) in Theorem 7.2 by setting \( I \) to be a \( \{C_m \mid m \in M\} \cup \{D_{m,n} \mid m \in M \land n \in N\} \cup \{E_\alpha \mid \alpha \in \text{Ord}^M \setminus S\} \)-generic filter on \( P \) (utilizing Lemma 7.1 (c)). Put \( i = \bigcup I \). It only remains to verify that

\[ \forall \alpha \in \text{Ord}^M \setminus S. \exists m \in M. (\text{rank}^M(m) = \alpha \land i(m) \neq m). \]

But this follows from that \( I \) intersects \( E_\alpha \), for each \( \alpha \in \text{Ord}^M \setminus S \).

The result above says in particular that every countable non-standard model of \( \text{KP}^+ + \Sigma_1^P\)-Separation has a proper rank-initial self-embedding. As a remark, there is a related theorem by Hamkins, where no initiality is required from the embedding. In particular, it is shown in Hamkins, 2013 that every countable model \( M \) of \( \text{KP} \) has a self-embedding \( i : M \to L^M \), where \( L^M \subseteq M \) is the Gödel constructible universe of \( M \).

The extra clause in the above Corollary, ensuring that something is moved on every rank above the cut, enables the following characterization.

**Theorem 7.9 (Bahrami-Enayat-style).** Let \( M \models \text{KP}^+ + \Sigma_1^P\)-Separation be countable and non-standard, and let \( S \) be a topless substructure of \( M \). The following are equivalent:

(a) \( S = \text{Fix}^\text{rank}(i) \), for some rank-initial self-embedding \( i : M \to M \).

(a') \( S = \text{Fix}^\text{rank}(i) \), for some proper topless rank-initial self-embedding \( i : M \to M \).

(b) \( S \) is rank-initial in \( M \).

**Proof.** (a) \( \Rightarrow \) (a') is immediate from the definition of \( \text{Fix}^\text{rank} \).

(a') \( \Rightarrow \) (b) follows from Corollary 7.8.
Theorem 7.10 (Wilkie-style). Suppose that $\mathcal{M} \models KP^P + \Sigma^P_2$-Separation + $\Pi^P_2$-Foundation and $\mathcal{N} \models KP^P$ are countable and non-standard. Let $\mathcal{S}$ be a common rank-cut of $\mathcal{M}$ and $\mathcal{N}$, and let $\beta \in \text{Ord}^\mathcal{N}$. Then the following are equivalent:

(a) For any ordinal $\alpha <^\mathcal{N} \beta$, there is a rank-initial embedding $i : \mathcal{M} \to \mathcal{N}$, fixing $S$ pointwise, such that $\mathcal{N}_\alpha \subseteq i(\mathcal{M}) \subseteq \mathcal{N}_\beta$.

(a') For any ordinal $\alpha <^\mathcal{N} \beta$, there is a rank-cut $i : \mathcal{M} \to \mathcal{N}$, fixing $S$ pointwise, such that $\mathcal{N}_\alpha \subseteq i(\mathcal{M}) \subseteq \mathcal{N}_\beta$.

(b) $\text{SSy}_S(\mathcal{M}) = \text{SSy}_S(\mathcal{N})$, and for all $s \in S$ and $\delta(x,y,z) \in \Delta^P_0[x,y,z]$:

$$(\mathcal{M}, s) \models \forall x. \exists y. \delta(x,y,s) \Rightarrow (\mathcal{N}, s) \models \forall x \in V_\beta. \exists y \in V_\beta. \delta(x,y,s).$$

Proof. $(\text{a}) \Rightarrow (\text{a}')$: It is easy to see that $(\text{a}) \Rightarrow (\text{a}')$ is proved just as for Theorem 7.10. Given Theorem 7.10 it only remains to show that $\mathcal{N} \models \forall x \in V_\beta. \exists y \in V_\beta. \delta(x,y,s)$. Let $a \in \mathcal{N}_\beta$ be arbitrary and set $\alpha = (\text{rank}(a) + 1)^N$. Since $\beta$ is a limit ordinal in $\text{Ord}$, there is a rank-initial embedding $i : \mathcal{M} \to \mathcal{N}$, such that $a \in \mathcal{M} \subseteq \mathcal{N}_\alpha$. Pick $m \in \mathcal{M}$ such that $\mathcal{M} \models \delta(a,m,s)$. Then $i(m) \in \mathcal{N}_\beta$ and, by Proposition 6.10, $\mathcal{N} \models \delta(i^{-1}(a),m,s)$, as desired.

$(\text{a}') \Rightarrow (\text{a})$: Let $\alpha <^\mathcal{N} \beta$ and let $n = V^{\mathcal{N}_\alpha}_\beta$. Using Lemma 6.13 and $\Delta^P_1$-Collection, let $d$ be a code in $\mathcal{N}$ for the following set:

$$D = \{ \delta(x,y,s) \mid \delta \in \Delta^P_0 \land s \in S \land \mathcal{N} \models \forall x \in V_\beta. \delta(x,n,s) \}. $$

Using $\text{SSy}(\mathcal{M}) = \text{SSy}(\mathcal{N})$ let $c$ be a code for this set in $\mathcal{M}$. Define the formulae

$$\phi_{<\beta}(\xi) := \exists y \in V_\beta. \forall \delta \in d \cap V_\xi. \forall x \in V_\beta. \text{Sat}_{\Delta^P_0}(\delta, x, y, s),$$

$$\phi(\xi) := \exists y. \forall \delta \in c \cap V_\xi. \forall x. \text{Sat}_{\Delta^P_0}(\delta, x, y, s).$$

Note that $\phi$ is $\Sigma^P_2$. Moreover, $c \cap V_\xi = d \cap V_\xi$ and $n$ witnesses $\phi_{<\beta}(\xi)$, for all ordinals $\xi \in S$. So by the second conjunct of $(\text{a}')$, $\mathcal{M} \models \phi(\xi)$ for all ordinals $\xi \in S$, whence by $\Sigma^P_2$-Overspill, $\mathcal{M} \models \phi(\mu)$ for some ordinal $\mu \in \mathcal{M} \setminus S$. Letting $m \in \mathcal{M}$ be a witness of this fact, we have $\mathcal{M} \models \forall \xi. \delta(x,m,s)$, for all $\delta(x,y,s) \in D$. Now $(\text{a})$ is obtained by plugging $m$ and $n$ into Theorem 7.10.

Corollary 7.11. Let $\mathcal{M} \models KP^P + \Sigma^P_2$-Separation + $\Pi^P_2$-Foundation and $\mathcal{N} \models KP^P + \Sigma^P_2$-Separation be countable and non-standard. Let $\mathcal{S}$ be a common rank-cut of $\mathcal{M}$ and $\mathcal{N}$. Then the following are equivalent:

(a) For any ordinal $\alpha \in \mathcal{N}$, there is a rank-initial embedding $i : \mathcal{M} \to \mathcal{N}$, fixing $S$ pointwise, such that $\mathcal{N}_\alpha \subseteq i(\mathcal{M})$.

(a') For any ordinal $\alpha \in \mathcal{N}$, there is a rank-cut $i : \mathcal{M} \to \mathcal{N}$, fixing $S$ pointwise, such that $\mathcal{N}_\alpha \subseteq i(\mathcal{M})$.

(b) $\text{SSy}(\mathcal{M}) = \text{SSy}(\mathcal{N})$, and $\text{Th}_{\Pi^P,S}(\mathcal{M}) \subseteq \text{Th}_{\Pi^P,S}(\mathcal{N})$.

Proof. $(\text{a}) \Rightarrow (\text{a}')$ is proved just as for Theorem 7.10.

$(\text{a}') \Rightarrow (\text{a})$ follows from Theorem 7.10 by letting $\beta >^\mathcal{N} \alpha$ be as obtained from Lemma 7.4.

Corollary 7.12. Let $\mathcal{M} \models KP^P + \Sigma^P_2$-Separation + $\Pi^P_2$-Foundation be countable and non-standard. Let $\mathcal{S}$ be a rank-cut of $\mathcal{M}$. For any $\alpha \in \text{Ord}^\mathcal{M}$, there is a rank-cut $i : \mathcal{M} \to \mathcal{M}$, fixing $S$ pointwise, such that $\mathcal{M}_\alpha \subseteq i(\mathcal{M})$ and

$$\forall \alpha \in \text{Ord}^\mathcal{M} \setminus S. \exists m \in \mathcal{M}. (\text{rank}^\mathcal{M}(m) = \alpha \land i(m) \neq m).$$
Proof. Let \( \mathcal{N} = \mathcal{M} \) and let \( \beta > \mathcal{M} \) \( \alpha \) be as obtained from Lemma \( \ref{lem:construction} \). Then condition (3) of Theorem \( \ref{thm:main} \) is satisfied. Repeat the proof of Theorem \( \ref{thm:main} \) (3) \( \Rightarrow \) (4)) with \( \mathcal{N} = \mathcal{M} \), except that at the last step: apply Theorem \( \ref{thm:main2} \) instead of Theorem \( \ref{thm:main1} \). 

Now that we have explored necessary and sufficient conditions for constructing embeddings between models, we turn to the question of constructing isomorphisms between models. For this purpose we shall restrict ourselves to recursively saturated models of ZF.

**Lemma 7.13.** Let \( \mathcal{M} \) and \( \mathcal{N} \) be countable recursively saturated models of ZF, and let \( \mathcal{S} \) be a common rank-initial-\( \omega \)-topless substructure of \( \mathcal{M} \) and \( \mathcal{N} \). Moreover, let \( \mathbb{P} = [\mathcal{M} \subseteq \mathcal{N}] \).

If \( \text{SSy}_{\mathcal{S}}(\mathcal{M}) \subseteq \text{SSy}_{\mathcal{S}}(\mathcal{N}) \), then

\[
\mathcal{C}_m' = \{ f \in \mathbb{P} | m \in \text{dom}(f) \}
\]

is dense in \( \mathbb{P} \), for each \( m \in \mathcal{M} \).

Proof. By Theorem \( \ref{thm:main} \), \( \mathcal{M} \) and \( \mathcal{N} \) are \( \omega \)-non-standard and there are expansions \( (\mathcal{M}, \text{Sat}^\mathcal{M}) \) and \( (\mathcal{N}, \text{Sat}^\mathcal{N}) \) satisfying condition (3) of that theorem. Recall that this condition says that these are satisfaction classes that are correct for all formulae in \( \mathcal{L}_0^0 \) of standard complexity, and that the expanded structures satisfy Separation and Replacement for all formulae in the expanded language \( \mathcal{L}_0^0 \).

Let \( g \in \mathbb{P} \). We unravel it as \( g = \{ (m_\xi, n_\xi) | \xi < \gamma \} \), for some \( \gamma < \omega \). Let \( m_\gamma \in \mathcal{M} \) be arbitrary. By \( \mathcal{L}_0^0 \)-Separation, there is a code \( c \) in \( \mathcal{M} \) for the set

\[
\{ (\delta, s) \in (\mathcal{L}_0^0[x_\xi, x_\gamma, z] \cap \mathcal{S}) \times \mathcal{S} | (\mathcal{M}, \text{Sat}^\mathcal{M}) \models \text{Sat}(\delta, (m_\xi, x_\gamma, m_\gamma, s)) \}.
\]

Since \( \text{SSy}_{\mathcal{S}}(\mathcal{M}) = \text{SSy}_{\mathcal{S}}(\mathcal{N}) \), this set is also coded by some \( d \) in \( \mathcal{N} \).

We define a formula:

\[
\phi(\zeta, k, (x_\xi)x_{\xi<\gamma}, q) \equiv \text{Ord}(\zeta) \wedge k < \omega \wedge \\
\exists x_\gamma, \forall \delta \in \Sigma_k \forall t \in V_\zeta, \\
(\text{Sat}(\delta, (x_\xi)x_{\xi<\gamma}, x_\gamma, t) \leftrightarrow (\delta, t) \in q).
\]

By construction of \( c \) and correctness of \( \text{Sat}^\mathcal{M} \), we have that

\[
\mathcal{M} \models \phi(\zeta, k, (n_\xi)x_{\xi<\gamma}, c),
\]

for each \( \zeta \in \text{Ord}^\mathcal{M} \cap \mathcal{S} \) and each \( k < \omega = \text{OSP}(\mathcal{M}) \). So since \( g \) is elementary, and since \( \mathcal{M}_\zeta = \mathcal{N}_\zeta \) and \( c_{\mathcal{M}} \cap c_{\mathcal{N}} = d_{\mathcal{M}} \cap c_\zeta \) for each \( \zeta \in \text{Ord}^\mathcal{M} \cap \mathcal{S} \), we also have that \( \mathcal{N} \models \phi(\zeta, k, (n_\xi)x_{\xi<\gamma}, d) \) for each \( \zeta \in \text{Ord}^\mathcal{N} \cap \mathcal{S} \) and each \( k < \omega \). Pick some \( \nu \in \text{Ord}^\mathcal{N} \setminus \mathcal{S} \). Now by Overspill on \( \mathcal{S} \), for each \( k < \omega \) there is \( \nu_k \in \text{Ord}^\mathcal{N} \setminus \mathcal{S} \) such that \( (\mathcal{N}, \text{Sat}^\mathcal{N}) \models (\mathcal{N}, \text{Sat}^\mathcal{N}) \models \phi(\zeta, k, (n_\xi)x_{\xi<\gamma}, \nu_k) \).

Pick some non-standard \( o <^\mathcal{N} \omega^\mathcal{N} \). Working in \( \mathcal{N} \), we construct a partial function \( (k \mapsto \nu_k) : o \rightarrow \nu + 1 \), such that for each \( k < o \),

\[
\nu_k = \sup\{ \zeta \mid \zeta < \nu \wedge \phi(\zeta, k, (n_\xi)x_{\xi<\gamma}, d) \}.
\]

We return to reasoning in the meta-theory. By the Overspill-argument above, this function is total on \( \omega \), and \( \nu_k \notin \mathcal{S} \) for each \( k < \omega \). Moreover, by logic, \( \nu_k \geq \nu_l \) for all \( k \leq l < \omega \). So by \( \omega \)-toplessness, there is \( \nu_\infty \in \text{Ord}^\mathcal{N} \setminus \mathcal{S} \), such that for each \( k < \omega \), \( \nu_\infty < \mathcal{N} \nu_k \). So for each \( k < \omega \), we have \( (\mathcal{N}, \text{Sat}^\mathcal{N}) \models (\mathcal{N}, \text{Sat}^\mathcal{N}) \models \phi(\zeta, k, (n_\xi)x_{\xi<\gamma}, d) \), whence by Overspill on WFP(\( \mathcal{N} \)), there is
a non-standard \( k_\infty \in \mathcal{N} \) such that \( (\mathcal{N}, \text{Sat}^\mathcal{N}) \models \phi(\nu_\infty, k_\infty, \langle n_\xi \rangle_{\xi < \gamma}, d) \). Let \( n_\gamma \in \mathcal{N} \) be a witness of this fact. Note that for all \( s \in \mathcal{S} \) and for all \( \delta \in L^0[\langle x_\xi \rangle_{\xi < \gamma}, x_\gamma, z] \),
\[
\mathcal{N} \models \delta(\langle n_\xi \rangle_{\xi < \gamma}, n_\gamma, s) \iff \mathcal{N} \models \langle \delta, s \rangle \in d.
\]

Let \( f = g \cup \{ (m_\gamma, n_\gamma) \} \). We need to show that \( f \in C_{m_\gamma} \); it only remains to verify that \( f \) is elementary. Now observe that for any \( s \in \mathcal{S} \), and any formula \( \delta(\langle x_\xi \rangle_{\xi < \gamma+1}, z) \in L^0[\langle x_\xi \rangle_{\xi < \gamma+1}, z] \),
\[
\mathcal{M} \models \delta(\langle m_\xi \rangle_{\xi < \gamma+1}, s) \iff \mathcal{M} \models \langle \delta, s \rangle \in c
\]
\[
\iff \mathcal{N} \models \langle \delta, s \rangle \in d
\]
\[
\iff \mathcal{N} \models \delta(\langle n_\xi \rangle_{\xi < \gamma+1}, s).
\]

Therefore, \( f \in C_{m_\gamma} \) as desired. \( \square \)

**Theorem 7.14.** Let \( \mathcal{M} \) and \( \mathcal{N} \) be countable recursively saturated models of ZF, and let \( \mathcal{S} \) be a common rank-initial \( \omega \)-topless substructure of \( \mathcal{M} \) and \( \mathcal{N} \). Let \( m_0 \in \mathcal{M} \) and let \( n_0 \in \mathcal{N} \). The following are equivalent:

(a) There is an isomorphism \( i : \mathcal{M} \to \mathcal{N} \), fixing \( \mathcal{S} \) pointwise, such that \( i(m_0) = n_0 \).

(b) \( \text{SSy}_\mathcal{S}(\mathcal{M}) = \text{SSy}_\mathcal{S}(\mathcal{N}) \) and \( \text{Th}_\mathcal{S}((\mathcal{M}, m_0)) = \text{Th}_\mathcal{S}((\mathcal{N}, n_0)) \).

**Proof.** The forward direction is clear since \( i \) is an isomorphism.

Let \( \mathbb{P} = [\mathcal{M} \leq^\mathcal{S}_n \omega] \). Since \( \text{Th}_\mathcal{S}((\mathcal{M}, m_0)) = \text{Th}_\mathcal{S}((\mathcal{N}, n_0)) \), the function \( (m_0 \mapsto n_0) \) is in \( \mathbb{P} \). For each \( m \in \mathcal{M} \) and each \( n \in \mathcal{N} \), let
\[
C_{m} = \{ f \in \mathbb{P} \mid m \in \text{dom}(f) \},
\]
\[
D_{n} = \{ f \in \mathbb{P} \mid n \in \text{image}(f) \}.
\]

By Lemma 7.13, \( C_{m} \) and \( D_{n} \) are dense in \( \mathbb{P} \) for all \( m \in \mathcal{M} \) and all \( n \in \mathcal{N} \). By Lemma 5.1, there is a \( C_{m} \cup D_{n} \)-generic filter \( \mathcal{I} \) on \( \mathbb{P} \) containing \( (m_0 \mapsto n_0) \). Let \( i = \bigcup \mathcal{I} \).

By the genericity, \( \text{dom}(i) = \mathcal{M} \) and \( \text{image}(i) = \mathcal{N} \). Moreover, by the filter properties, for any \( \bar{m} \in \mathcal{M} \), some finite extension \( f \in \mathbb{P} \) of \( i \mid \bar{m} \) is in \( \mathcal{I} \). So by elementarity of \( f \) and arbitrariness of \( \bar{m} \), we have that \( i \) is an isomorphism. \( \square \)

The following Theorem is an improvement of Theorem 6.14. The proof given here is meant to be simpler and more accessible than the one given in [Ressayre, 1987a].

**Theorem 7.15** (Ressayre). Let \( \mathcal{M} \) be a countable recursively saturated model of ZF. There are unboundedly many \( \alpha \in \text{Ord}^\mathcal{M} \), such that for all \( S \in \mathcal{M}_\alpha \) we have \( \mathcal{M} \cong_{S, \mathcal{M}} \mathcal{M}_\alpha \cong \mathcal{M} \).

**Proof.** Let \( \alpha >^\mathcal{M} \omega^\mathcal{M} \) be as obtained from Theorem 6.14. Thus \( \mathcal{M}_\alpha \cong \mathcal{M} \). Let \( S \in \mathcal{M}_\alpha \) be arbitrary. For each \( m \in \mathcal{M} \omega^\mathcal{M} \), let \( \sigma_m = \text{rank}(S) + m \) as evaluated in \( \mathcal{M} \). Since \( \mathcal{M}_\alpha \cong \mathcal{M} \), we have \( \sigma_m < \alpha \) for each \( m \in \mathcal{M} \omega^\mathcal{M} \).

Since \( \mathcal{M} \) is recursively saturated, it is \( \omega \)-non-standard. Let \( \mathcal{M}_S^\omega = \bigcup_{k<\omega} \mathcal{M}_{S_k} \) (note that we take this union only over standard \( k \)). By Lemma 6.7, \( \mathcal{M}_S^\omega \) is a common rank-initial \( \omega \)-topless substructure of \( \mathcal{M} \) and \( \mathcal{M}_\alpha \); and obviously \( S, \mathcal{M} \subseteq \mathcal{M}_S^\omega \).

By rank-initiality, \( \text{SSy}_\mathcal{M}_{S, \omega}((\mathcal{M}_\alpha)) = \text{SSy}_\mathcal{M}_{S, \omega}((\mathcal{M})) \), and by \( \mathcal{M}_\alpha \cong \mathcal{M} \), we have \( \text{Th}_{\mathcal{M}_{S, \omega}}((\mathcal{M}_\alpha)) = \text{Th}_{\mathcal{M}_{S, \omega}}((\mathcal{M})) \). So it follows from Theorem 7.11 that \( \mathcal{M} \cong_{S, \mathcal{M}} \mathcal{M}_\alpha \). \( \square \)
**Theorem 7.16** (Ressayre-style). Let $\mathcal{M} \models KP^+$ be countable and non-standard. The following are equivalent:

(a) $\mathcal{M} \models \Sigma^P_1$-Separation.

(b) For every $\alpha \in \text{Ord}^\mathcal{M}$, there is a proper rank-initial self-embedding of $\mathcal{M}$ which fixes $\mathcal{M}_\alpha$ pointwise.

**Proof.** (a) $\Rightarrow$ (b): Let $\mathcal{N} = \bigcup_{\xi \in \text{OSP}(\mathcal{M})} \mathcal{M}_{\alpha + \xi}$. Note that $\mathcal{N}$ is a rank-cut of $\mathcal{M}$. So by Theorem 7.8, we are done.

(b) $\Rightarrow$ (a): Let $\phi(x) \in \Sigma^P_1[x]$ and let $a \in \mathcal{M}$. Let $i$ be a rank-initial self-embedding of $\mathcal{M}$ which fixes $\mathcal{M}_{\text{rank}(a) + 1, \mathcal{M}}$ pointwise, which satisfies $i(\mathcal{M}) \subseteq \mathcal{M}_\mu$, for some $\mu \in \text{Ord}^\mathcal{M}$. Let $\mathcal{M}$ be a bijection coded in $\mathcal{M}$.

So $\{ x \in a \mid (\exists y, \delta(y, x)) \}$, which exists by $\Delta^P_0$-Separation. 

\[ \square \]

8 Iterated ultrapowers with special self-embeddings

It is convenient to fix some objects which will be discussed throughout this section. Fix a countable model $(\mathcal{M}, \mathcal{A}) \models \text{GBC} + \text{“Ord is weakly compact”}$. Fix $\mathcal{B}$ to be the boolean algebra $\{ A \subseteq \text{Ord}^\mathcal{M} \mid A \in \mathcal{A} \}$ induced by $\mathcal{A}$. Fix $\mathcal{P}$ to be the partial order of unbounded sets in $\mathcal{B}$ ordered under inclusion. Fix a filter $\mathcal{U}$ on $\mathcal{P}$. Note that by Proposition 5.1 $(\mathcal{M}, \mathcal{A}) \models \text{Global Choice}$.

$\mathcal{U}$ is $\mathcal{P}$-generic over $(\mathcal{M}, \mathcal{A})$, or simply $(\mathcal{M}, \mathcal{A})$-generic, if it intersects every dense subset of $\mathcal{P}$ that is parametrically definable in $(\mathcal{M}, \mathcal{A})$. $\mathcal{U}$ is $(\mathcal{M}, \mathcal{A})$-complete if for every $a \in \mathcal{M}$ and every $f : \text{Ord}^\mathcal{M} \rightarrow a_M$ that is coded in $\mathcal{A}$, there is $b \in a_M$ such that $f^{-1}(b) \in \mathcal{U}$. Considering the characteristic functions of the classes in $\mathcal{A}$, we can easily see that if $\mathcal{U}$ is $(\mathcal{M}, \mathcal{A})$-complete, then it is an ultrafilter on $\mathcal{B}$, i.e. for any $A \in \mathcal{B}$, we have $A \in \mathcal{U}$ or $\text{Ord}^\mathcal{M} \setminus A \in \mathcal{U}$.

Let $P : \text{Ord}^\mathcal{M} \times \text{Ord}^\mathcal{M} \rightarrow \text{Ord}^\mathcal{M}$ be a bijection coded in $\mathcal{A}$. For each $g : \text{Ord}^\mathcal{M} \rightarrow \{0, 1\}^\mathcal{M}$ coded in $\mathcal{A}$, and each $\alpha \in \text{Ord}^\mathcal{M}$, define $S^g_\alpha = \{ \xi \in \text{Ord}^\mathcal{M} \mid g(P(\alpha, \xi)) = 1 \}$. Thus, $g$ may be thought of as coding an $\text{Ord}^\mathcal{M}$-sequence of sets; indeed $(\alpha \mapsto S^g_\alpha) : \text{Ord}^\mathcal{M} \rightarrow \mathcal{B}$. $\mathcal{U}$ is $(\mathcal{M}, \mathcal{A})$-iterable if for every $g : \text{Ord}^\mathcal{M} \rightarrow \{0, 1\}^\mathcal{M}$ coded in $\mathcal{A}$, we have $\{ \alpha \mid S^g_\alpha \in \mathcal{U} \} \in \mathcal{A}$.

A filter $\mathcal{U}$ is $(\mathcal{M}, \mathcal{A})$-canonically Ramsey if for every $n \in \mathbb{N}$ and $f : [\text{Ord}^\mathcal{M}]^n \rightarrow \text{Ord}^\mathcal{M}$ coded in $\mathcal{A}$, there is $H \in \mathcal{U}$ and $S \subseteq \{1, \ldots, n\}$, such that for any $\alpha_1, \ldots, \alpha_n$ and $\beta_1, \ldots, \beta_n$ in $H$,

$$f(\alpha_1, \ldots, \alpha_n) = f(\beta_1, \ldots, \beta_n) \iff \forall m \in S. \alpha_m = \beta_m.$$ 

We say that $f$ is canonical on $H$.

The following theorem is proved in [Enayat, 2004, p. 48]. Combined with Lemma 5.1 it establishes the existence of an ultrafilter on $\mathcal{B}$, which is $(\mathcal{M}, \mathcal{A})$-complete, $(\mathcal{M}, \mathcal{A})$-iterable and $(\mathcal{M}, \mathcal{A})$-canonically Ramsey, under the assumption that $(\mathcal{M}, \mathcal{A}) \models \text{“Ord is weakly compact”}$. 

**Theorem 8.1.** Let $(\mathcal{M}, \mathcal{A})$ a model of GBC+ “Ord is weakly compact”. If $\mathcal{U}$ is $(\mathcal{M}, \mathcal{A})$-generic, then $\mathcal{U}$ is

(a) $(\mathcal{M}, \mathcal{A})$-complete,

(b) $(\mathcal{M}, \mathcal{A})$-iterable, and

(c) $(\mathcal{M}, \mathcal{A})$-canonically Ramsey.
Using such an ultrafilter, we shall now construct an iterated ultrapower of \((\mathcal{M}, \mathcal{A})\). A more detailed account of this construction is found in \cite{Enayat, Kauflmann, McKenzie, 2017}.

**Construction 8.2.** Suppose that \(\mathcal{U}\) is a non-principal \((\mathcal{M}, \mathcal{A})\)-iterable ultrafilter on \(\mathbb{B}\). Then for any \(n \in \mathbb{N}\), an ultrafilter \(\mathcal{U}^n\) can be recursively constructed on \(\mathbb{B}^n = \{ \{ A \in \mathcal{A} \} \mid A \subseteq (\mathcal{M})^n \}\) as follows:

First, we extend the definition of iterability. An ultrafilter \(\mathcal{V}\) on \(\mathbb{B}^n\) is \((\mathcal{M}, \mathcal{A})\)-iterable if for any function \(\alpha \mapsto S_\alpha : \text{Ord}^M \rightarrow \mathbb{B}^n\) coded in \(\mathcal{A}\), we have \(\{ \alpha \mid S_\alpha \in \mathcal{V} \} \in \mathcal{A}\).

\(\mathcal{U}^0\) is the trivial (principal) ultrafilter \(\{ \emptyset \}\) on the boolean algebra \(\{ \emptyset, \{ \emptyset \} \}\), where \(\emptyset\) is the empty tuple.

For any \(n \in \mathbb{N}\), \(X \in \mathbb{B}^{n+1}\) and any \(\alpha \in \text{Ord}^M\), define

\[
X_\alpha = \{ \{ \alpha_2, \ldots, \alpha_{n+1} \} \mid \{ \alpha, \alpha_2, \ldots, \alpha_{n+1} \} \in X \}
\]

\[
X \in \mathcal{U}^{n+1} \iff \{ \alpha \mid X_\alpha \in \mathcal{U}^n \} \in \mathcal{U}.
\]

Note that there are other equivalent definitions:

\[
X \in \mathcal{U}^n \iff \{ \{ \alpha_2, \ldots, \alpha_n \} \mid \{ \alpha, \alpha_2, \ldots, \alpha_n \} \in X \in \mathcal{U}^{n-1} \} \in \mathcal{U}.
\]

By the setup, \(\mathcal{U}^1 = \mathcal{U}\), which is an \((\mathcal{M}, \mathcal{A})\)-iterable ultrafilter on \(\mathbb{B}^1\) by assumption. Assuming that \(\mathcal{U}^n\) is an \((\mathcal{M}, \mathcal{A})\)-iterable ultrafilter on \(\mathbb{B}^n\), we shall show that \(\mathcal{U}^{n+1}\) is an \((\mathcal{M}, \mathcal{A})\)-iterable ultrafilter on \(\mathbb{B}^{n+1}\).

Let \(X \in \mathcal{U}^{n+1}\). If \(X \subseteq Y \in \mathbb{B}^{n+1}\), then \(X_\alpha \subseteq Y_\alpha\), for each \(\alpha \in \text{Ord}^M\), and by iterability of \(\mathcal{U}^n\), \(\{ \alpha \mid Y_\alpha \in \mathcal{U} \} \in \mathcal{A}\). So \(Y \in \mathcal{U}^{n+1}\) by upwards closure of \(\mathcal{U}^n\) and \(\mathcal{U}\). Similarly, the iterability of \(\mathcal{U}^n\) and the finite intersection and maximality properties of \(\mathcal{U}^n\) and \(\mathcal{U}\) imply that \(\mathcal{U}^{n+1}\) has the finite intersection and maximality properties, respectively. To show iterability, suppose that the function \(\xi \mapsto S^\xi_\alpha : \text{Ord}^M \rightarrow \mathbb{B}^{n+1}\) is coded in \(\mathcal{A}\). Then

\[
\{ \xi \mid S^\xi_\alpha \in \mathcal{U}^{n+1} \} = \{ \xi \mid \{ \alpha \mid S^\xi_\alpha \in \mathcal{U}^n \} \in \mathcal{U} \} \in \mathcal{A}
\]

by iterability of \(\mathcal{U}\). So \(\mathcal{U}^{n+1}\) is also \((\mathcal{M}, \mathcal{A})\)-iterable. We have proved:

**Lemma 8.3.** If \(\mathcal{U}\) is an \((\mathcal{M}, \mathcal{A})\)-iterable ultrafilter on \(\mathbb{B}\), then \(\mathcal{U}^n\) is an \((\mathcal{M}, \mathcal{A})\)-iterable ultrafilter on \(\mathbb{B}^n\), for every \(n \in \mathbb{N}\).

Since \(\mathcal{U}\) is a non-principal ultrafilter, it contains all final segments of \(\text{Ord}^M\). So by induction, we have

\[
\{ \{ \alpha_1, \ldots, \alpha_n \} \mid \alpha_1 < \cdots < \alpha_n \in \text{Ord}^M \} \in \mathcal{U}^n,
\]

for every \(n \in \mathbb{N}\).

Lastly, we shall extend the definition of completeness and show that each \(\mathcal{U}^n\) has this property. An ultrafilter \(\mathcal{V}\) on \(\mathbb{B}^n\) is \((\mathcal{M}, \mathcal{A})\)-complete if for any \(m < n\) and any functions \(f : (\text{Ord}^M)^m \rightarrow M\) and \(g : (\text{Ord}^M)^n \rightarrow M\) coded in \(\mathcal{A}\), such that

\[
\{ \{ \alpha_1, \ldots, \alpha_m \} \mid g(\alpha_1, \ldots, \alpha_m) \in f(\alpha_1, \ldots, \alpha_m) \} \in \mathcal{V}^m,
\]

we have that \(\mathcal{A}\) codes a function \(f' : (\text{Ord}^M)^m \rightarrow M\), such that

\[
\{ \{ \alpha_1, \ldots, \alpha_n \} \mid g(\alpha_1, \ldots, \alpha_n) = f'(\alpha_1, \ldots, \alpha_m) \} \in \mathcal{V}^n.
\]
Lemma 8.4. If $\mathcal{U}$ is an $(\mathcal{M}, \mathcal{A})$-complete and $(\mathcal{M}, \mathcal{A})$-iterable ultrafilter, then $\mathcal{U}^n$ is $(\mathcal{M}, \mathcal{A})$-complete, for every $n \in \mathbb{N}$.

Proof. Suppose that $m < n$ and that
\[
\begin{align*}
f : (\text{Ord}^\mathcal{M})^m &\rightarrow \mathcal{M} \\
g : (\text{Ord}^\mathcal{M})^n &\rightarrow \mathcal{M}
\end{align*}
\]
satisfy
\[
\{ (\alpha_1, \ldots, \alpha_n) \mid g(\alpha_1, \ldots, \alpha_n) \in f(\alpha_1, \ldots, \alpha_m) \} \in \mathcal{U}^n.
\]
We may assume that $m + 1 = n$. The above is equivalent to
\[
\mathcal{A} = \text{df} \{ (\alpha_1, \ldots, \alpha_m) \mid \{ \alpha_n \mid g(\alpha_1, \ldots, \alpha_n) \in f(\alpha_1, \ldots, \alpha_m) \} \in \mathcal{U} \} \in \mathcal{U}^m.
\]
Moreover, by completeness of $\mathcal{U}$, for any $\langle \alpha_1, \ldots, \alpha_m \rangle \in \mathcal{A}$, there is $y \in f(\alpha_1, \ldots, \alpha_m)$ such that
\[
\{ \alpha_n \mid g(\alpha_1, \ldots, \alpha_n) = y \} \in \mathcal{U}.
\]
On the other hand, we have by iterability of $\mathcal{U}$ (utilizing a bijection coded in $\mathcal{A}$ between $\text{Ord}^\mathcal{M}$ and $\mathcal{M}^n$) that
\[
f' = \text{df} \{ \langle \alpha_1, \ldots, \alpha_m, y \rangle \mid \{ \alpha_n \mid g(\alpha_1, \ldots, \alpha_n) = y \} \in \mathcal{U} \} \in \mathcal{A}.
\]
Since $\mathcal{U}$ is an ultrafilter, $f'$ is a function whose domain is a superset of $\mathcal{A} \in \mathcal{U}$, and by extending it arbitrarily we may assume its domain is $(\text{Ord}^\mathcal{M})^m$. Now by $(\dagger)$, we have
\[
\{ \langle \alpha_1, \ldots, \alpha_m \rangle \mid \{ \alpha_n \mid g(\alpha_1, \ldots, \alpha_n) = f'(\alpha_1, \ldots, \alpha_m) \} \in \mathcal{U} \} \in \mathcal{U}^m.
\]
Thus
\[
\{ (\alpha_1, \ldots, \alpha_n) \mid g(\alpha_1, \ldots, \alpha_n) = f'(\alpha_1, \ldots, \alpha_m) \} \in \mathcal{U}^n,
\]
as desired. \qed

Construction 8.5. Let $\mathcal{L}_\mathcal{A}^0$ be the language obtained from $\mathcal{L}^0$ by adding constant symbols for all elements of $\mathcal{M}$ and adding relation and function symbols for all relations and functions on $\mathcal{M}$ coded in $\mathcal{A}$. $(\mathcal{M}, \mathcal{A})_{A \in \mathcal{A}}$ denotes the canonical expansion of $\mathcal{M}$ to $\mathcal{L}_\mathcal{A}^0$ determined by $(\mathcal{M}, \mathcal{A})$. Assume that $\mathcal{U}$ is a non-principal $(\mathcal{M}, \mathcal{A})$-iterable ultrafilter on $\text{Ord}^\mathcal{M}$ and let $\mathbb{L}$ be a linear order. We construct $\text{Ult}_{\mathcal{U}, \mathbb{L}}((\mathcal{M}, \mathcal{A}))$ as follows:

1. For each $n \in \mathbb{N}$, define
   \[
   \Gamma_n = \text{df} \{ \phi(x_1, \ldots, x_n) \in \mathcal{L}_\mathcal{A}^0 \mid \{ \langle \alpha_1, \ldots, \alpha_n \rangle \mid (\mathcal{M}, A)_{A \in \mathcal{A}} \models \phi(\alpha_1, \ldots, \alpha_n) \} \in \mathcal{U}^n \}.
   \]
   Since $\mathcal{U}^n$ is an ultrafilter on $(\text{Ord}^\mathcal{M})^n$, each $\Gamma_n$ is a complete $n$-type over $\mathcal{M}$ in the language $\mathcal{L}_\mathcal{A}^0$. Moreover, each $\Gamma_n$ contains the elementary diagram of $(\mathcal{M}, \mathcal{A})_{A \in \mathcal{A}}$.

2. For each $l \in \mathbb{L}$, let $c_l$ be a new constant symbol, and let $\mathcal{L}_\mathcal{A}^0_{\mathbb{L}}$ be the language generated by $\mathcal{L}_\mathcal{A}^0 \cup \{ c_l \mid l \in \mathbb{L} \}$. Define
   \[
   T_{\mathcal{U}, \mathbb{L}} = \text{df} \{ \phi(c_1, \ldots, c_n) \in \mathcal{L}_\mathcal{A}^0_{\mathbb{L}} \mid n \in \mathbb{N} \land (l_1 <_L \cdots <_L l_n \in \mathbb{L} \land \phi(x_1, \ldots, x_n) \in \Gamma_n) \}.
   \]
   $T_{\mathcal{U}, \mathbb{L}}$ is complete and contains the elementary diagram of $(\mathcal{M}, \mathcal{A})$, because the same holds for each $\Gamma_n$. By Construction 8.2,
   \[
   T_{\mathcal{U}, \mathbb{L}} \models c_{l_1} < c_{l_2} \in \text{Ord}, \text{ for any } l_1 <_L l_2.
   \]
Moreover, $T_{\mathcal{U}, \mathbb{L}}$ has definable Skolem functions: For each $L_{\mathcal{A}, \mathbb{L}}$-formula $\exists x. \phi(x)$, we can prove in $T_{\mathcal{U}, \mathbb{L}}$ that the set of witnesses of $\exists x. \phi(x, y)$ of least rank exists, and provided this set is non-empty an element is picked out by a global choice function coded in $\mathbb{A}$. Thus we can define the iterated ultrapower of $(\mathcal{M}, \mathbb{A})$ modulo $\mathcal{U}$ along $\mathbb{L}$ as

$$\text{Ult}_{\mathcal{U}, \mathbb{L}}(\mathcal{M}, \mathbb{A}) \overset{df}{=} \text{the prime model of } T_{\mathcal{U}, \mathbb{L}}.$$

In particular, every element of $\text{Ult}_{\mathcal{U}, \mathbb{L}}(\mathcal{M}, \mathbb{A})$ is of the form $f(c_1, \ldots, c_n)$, where $l_1 < \cdots < l_n \in \mathbb{L}$ and $f \in \mathbb{A}$ (considered as a function symbol of $L_{\mathcal{A}, \mathbb{L}}$). Note that for any $A \in \mathbb{A}$, any function $f$ coded in $\mathbb{A}$ and for any $l_1, \ldots, l_n \in \mathbb{L}$, where $n \in \mathbb{N}$, we have

$$\text{Ult}_{\mathcal{U}, \mathbb{L}}(\mathcal{M}, \mathbb{A}) \models f(c_1, \ldots, c_n) \in A \iff \{\xi \in \text{Ord}^\mathcal{M} \mid (\mathcal{M}, A) \in A \models f(\xi) \in A\} \in \mathcal{U}.$$  

A different way of saying the same thing:

$$A^{\text{Ult}_{\mathcal{U}, \mathbb{L}}(\mathcal{M}, \mathbb{A})} = \{(f(c_1, \ldots, c_n))^{\text{Ult}_{\mathcal{U}, \mathbb{L}}(\mathcal{M}, \mathbb{A})} \mid \{\xi \in \text{Ord}^\mathcal{M} \mid (\mathcal{M}, A) \in A \models f(\xi) \in A\} \in \mathcal{U}\}.$$  

Since $T_{\mathcal{U}, \mathbb{L}}$ contains the elementary diagram of $(\mathcal{M}, \mathbb{A})$, the latter embeds elementarily in $\text{Ult}_{\mathcal{U}, \mathbb{L}}(\mathcal{M}, \mathbb{A})$. For simplicity of presentation, we assume that this is an elementary extension. Note that if $\mathbb{L}$ is empty, then $\text{Ult}_{\mathcal{U}, \mathbb{L}}(\mathcal{M}, \mathbb{A}) = (\mathcal{M}, \mathbb{A})$. If $\mathcal{U}$ is non-principal, then it is easily seen from Construction [2] that for any $l, l' \in \mathbb{L}$ and any $\alpha \in \text{Ord}^\mathcal{M}$,

$$l \leq_{\mathbb{L}} l' \iff \alpha \leq_{\mathbb{L}} c_l <_{\mathbb{L}} c_{l'},$$

where $\mathbb{D} = \text{Ord}^{\text{Ult}_{\mathcal{U}, \mathbb{L}}(\mathcal{M}, \mathbb{A})}$. So $\mathbb{L}$ embeds into the linear order of the ordinals in $\text{Ult}_{\mathcal{U}, \mathbb{L}}(\mathcal{M}, \mathbb{A})$, above the ordinals of $\mathcal{M}$.

It will be helpful to think of the ultrapower as a function (actually functor) of $\mathbb{L}$ rather than as a function of $(\mathcal{M}, \mathbb{A})$, so we introduce the alternative notation

$$G_{\mathcal{U}, (\mathcal{M}, \mathbb{A})}(\mathbb{L}) = \text{Ult}_{\mathcal{U}, \mathbb{L}}(\mathcal{M}, \mathbb{A}).$$

Suppose that $(\mathcal{M}, \mathbb{A})$ is a countable model of GBC + “Ord is weakly compact” and let $\mathcal{U}$ be an iterable non-principal ultrafilter on $\mathbb{B}$. Given an embedding $i : \mathbb{K} \rightarrow \mathbb{L}$, we construct an embedding

$$G_{\mathcal{U}, (\mathcal{M}, \mathbb{A})}(i) : G_{\mathcal{U}, (\mathcal{M}, \mathbb{A})}(\mathbb{K}) \rightarrow G_{\mathcal{U}, (\mathcal{M}, \mathbb{A})}(\mathbb{L})$$

as follows: Note that any $\alpha \in G_{\mathcal{U}, (\mathcal{M}, \mathbb{A})}(\mathbb{K})$ is of the form $f(c_{k_1}, \ldots, c_{k_n})$ for some $f \in \mathbb{A}$, $n \in \mathbb{N}$ and $k_1, \ldots, k_n \in \mathbb{K}$. Define $G_{\mathcal{U}, (\mathcal{M}, \mathbb{A})}(i)(\alpha) = f(c_{i(k_1)}, \ldots, c_{i(k_n)}).$

As shown in Theorem [5.6] $G_{\mathcal{U}, (\mathcal{M}, \mathbb{A})}(i)$ is an elementary embedding, and further, $G_{\mathcal{U}, (\mathcal{M}, \mathbb{A})}$ is a functor from the category of linear orders, with embeddings as morphisms, to the category of models of the $L_{\mathcal{A}, \mathbb{L}}$-theory of $(\mathcal{M}, A)_{A \in \mathbb{A}}$, with elementary embeddings as morphisms. We call this the Gaifman functor of $\mathcal{U}, (\mathcal{M}, \mathbb{A})$ and denote it by $G_{\mathcal{U}, (\mathcal{M}, \mathbb{A})}$, or just $G$ for short.

Gaifman [Gaifman, 1976] essentially proved the theorem below for models of arithmetic. A substantial chunk of its generalization to models of set theory was proved for specific needs in [Enayat, 2004].

**Theorem 8.6** (Gaifman-style). Suppose that $(\mathcal{M}, \mathbb{A}) \models \text{GBC} + \text{“Ord is weakly compact”}$ is countable and let $\mathcal{U}$ be an $(\mathcal{M}, \mathbb{A})$-generic ultrafilter. Write $G = G_{\mathcal{U}, (\mathcal{M}, \mathbb{A})}$ for the corresponding Gaifman functor. Let $i : \mathbb{K} \rightarrow \mathbb{L}$ be an embedding of linear orders.
(a) For each \( n \in \mathbb{N} \) and each \( \phi(x_1, \ldots, x_n) \in L^n_{\mathcal{A}, L} \):
\[
G(L) \models \phi(c_{i_1}, \ldots, c_{i_n}) \iff \\
\{(\alpha_1, \ldots, \alpha_n) \in (\text{Ord}^M)^n \mid (M, A)_{A \in A} \models \phi(\alpha_1, \ldots, \alpha_n)\} \in U^n.
\]

(b) \( G(i) : G(\mathbb{K}) \to G(L) \) is an elementary embedding.

(c) \( G \) is a functor.

(d) If \( L \neq \emptyset \), then \( SSy_M(G(L)) = (M, A) \).

(e) \( |G(L)| = |L| + \aleph_0 \).

(f) \( i \) is initial iff \( G(i) \) is rank-initial.

(g) \( i \) is an isomorphism iff \( G(i) \) is an isomorphism.

(h) Let \( l_0 \in L \). \( i \) is strictly bounded above by \( l_0 \) iff \( G(i) \upharpoonright_{\text{Ord}(K)} \) is strictly bounded above by \( c_{l_0} \).

(i) If \( L \setminus i(K) \) has no least element, then \( \{c_l \mid l \in L \setminus i(K)\} \) is downwards cofinal in \( \text{Ord}G(L) \setminus \text{Ord}G(i(K)) \).

(j) Let \( \mathbb{L}' \) be a linear order and let \( j, j' : L \to \mathbb{L}' \) be embeddings. \( i \) is an equalizer of \( j, j' : L \to L' \) iff \( G(i) \) is an equalizer of \( G(j), G(j') : G(\mathbb{L}) \to G(\mathbb{L}') \).

(k) Let \( i' : K \to L \) be an embedding. We have \( \forall k \in K. i(k) < i'(k) \) iff \( \forall \xi \in \text{Ord}G(K) \setminus \text{Ord}^M. G(i)(\xi) < G(i')(\xi) \).

Remark. \( (b) \) and \( (f) \) imply that \( (M, A) \) is a rank-initial elementary substructure of \( G(L) \). It follows from \( (b) \) that if \( j : L \to L \) is a self-embedding with no fixed point, then the fixed point set of \( G(j) \) is \( M \) (consider the equalizer of \( j \) and \( \text{id}_L \)). It follows from \( (b) \) that \( i : L \to L \) is contractive iff \( G(i) \) is contractive on \( M \setminus S \).

Proof. \( (a) \) This is immediate from Construction \( 8.5 \)

\( (b) \) We may assume that \( K \subseteq L \) and that \( i \) is the corresponding inclusion function. This has the convenient consequence that \( L^n_{\mathcal{A}, K} \subseteq L^n_{\mathcal{A}, L} \). Let \( \phi(\vec{c}) \in L^n_{\mathcal{A}, K} \) be a sentence, where \( \vec{c} \) is a tuple of constants. By \( (a) \),
\[
G(K) \models \phi(\vec{c}) \iff G(L) \models \phi(\vec{c}).
\]
Since every element of \( G(K) \) interprets a term, this equivalence establishes \( G(K) \preceq G(L) \), as \( L^n_{\mathcal{A}, K} \)-structures.

\( (c) \) It is clear that \( G(\text{id}_L) = \text{id}_{G(L)} \). It only remains to verify that composition is preserved. Let \( j : L \to \mathbb{L}' \) and \( j' : \mathbb{L}' \to \mathbb{L}'' \) be embeddings of linear orders. Let \( a \) be an arbitrary element of \( G(L) \). Then \( a = f(c_{l_1}, \ldots, c_{l_n}) \), for some \( f \in A, n \in \mathbb{N} \) and \( l_1, \ldots, l_n \in L \). \( G(j' \circ j)(a) = f(c_{j'(l_1)}, \ldots, c_{j'(l_n)}) = f(c_{j(l_1)}, \ldots, c_{j(l_n)}) = (G(j') \circ G(j))(a) \), as desired.

\( (d) \) We start with \( M \subseteq \text{Cod}_A(G(L)) \): Let \( A \in A \). Since \( (M, A) \models \text{GBC} \), the function \( f_A : \text{Ord}^M \to M \), defined by \( f_A(\xi) = V_\xi \cap A \) for all \( \xi \in \text{Ord}^M \), is coded in \( A \). Since \( L \neq \emptyset \), let \( l \in L \). Now by \( (c) \), for each \( a \in M \),
\[
G(L) \models a \in f_A(c_l) \\
\iff \{a \in \text{Ord}^M \mid (M, A)_{A \in A} \models a \in f_A(a)\} \in U \\
\iff a \in A,
\]
so \( f_A(c_l) \) codes \( A \).
We proceed with $\text{Cod}_{\mathcal{M}}(G(\mathbb{L})) \subseteq \mathcal{A}$. Let $b \in G(\mathbb{L})$. Then $G(\mathbb{L}) \models b = f(c_i, \ldots, c_n)$, for some $n \in \mathbb{N}$ and $l_1, \ldots, l_n \in \mathbb{L}$. We need to show that

$$\{ x \in \mathcal{M} \mid G(\mathbb{L}) \models x = f(c_i, \ldots, c_n) \} \in \mathcal{A}. $$

By (3), this amounts to showing that

$$\{ x \in \mathcal{M} \mid \{ (\alpha_1, \ldots, \alpha_n) \in \text{Ord}^\mathcal{M}^n \mid (\mathcal{M}, A)_{A \in \mathcal{A}} \models x = f(\alpha_1, \ldots, \alpha_n) \} \in \mathcal{U}^n \} \in \mathcal{A}. $$

Letting $w : \text{Ord}^\mathcal{M} \to \mathcal{M}$ be a well-ordering of $\mathcal{M}$ coded in $\mathcal{A}$, the above is equivalent to

$$\{ \xi \in \text{Ord}^\mathcal{M} \mid \{ (\alpha_1, \ldots, \alpha_n) \in \text{Ord}^\mathcal{M}^n \mid (\mathcal{M}, A)_{A \in \mathcal{A}} \models w(\xi) = f(\alpha_1, \ldots, \alpha_n) \} \in \mathcal{U}^n \} \in \mathcal{A}. $$

The last statement holds since $\mathcal{U}^n$ is $(\mathcal{M}, \mathcal{A})$-iterable on $\mathbb{R}^n$.

(4) Since $(\mathcal{M}, \mathcal{A})$ is countable, $|L| + \aleph_0 = |\mathcal{L}_{\mathcal{M}, \mathcal{A}}|$. So since $G(\mathbb{L})$ is a prime model in that language, we have $|G(\mathbb{L})| = |L| + \aleph_0$.

(3) We may assume that $\mathbb{L}$ extends $\mathbb{K}$ and that $G(\mathbb{L})$ extends $G(\mathbb{K})$. By Proposition 6.4, it suffices to show that $i$ is initial. Let $a \in G(\mathbb{K})$ and $b \in G(\mathbb{L})$, such that $G(\mathbb{L}) \models b = a$. We need to show that $b \in G(\mathbb{K})$. Note that $G(\mathbb{K}) \models a = f(c_1, \ldots, c_n)$ and $G(\mathbb{L}) \models b = g(c_1, \ldots, c_m)$, for some $m \leq n \in \mathbb{N}$, $l_1, \ldots, l_m \in \mathbb{K}$, $l_{m+1}, \ldots, l_n \in \mathbb{L}$ and $f, g \in \mathcal{A}$. By (3), we have that

$$\{\alpha_1, \ldots, \alpha_n \mid (\mathcal{M}, A) \models g(\alpha_1, \ldots, \alpha_n) = f'(\alpha_1, \ldots, \alpha_m) \} \in \mathcal{U}^n. $$

So by $(\mathcal{M}, \mathcal{A})$-completeness of $\mathcal{U}$ and Lemma 8.3, there is $f' : \text{Ord}^\mathcal{M}^n \to \mathcal{M}$ in $\mathcal{A}$, such that

$$\{\alpha_1, \ldots, \alpha_n \mid (\mathcal{M}, A) \models g(\alpha_1, \ldots, \alpha_n) = f'(\alpha_1, \ldots, \alpha_m) \} \in \mathcal{U}^n, $$

whence $G(\mathbb{L}) \models b = f'(c_1, \ldots, c_m)$. But $f'(c_1, \ldots, c_m) \in G(\mathbb{K})$. So $i$ is initial.

(5) $(\Leftarrow)$ follows from that the orderings embed into the respective sets of ordinals of the models, and that any isomorphism of the models preserves the order of their ordinals. $(\Rightarrow)$ follows from that functors preserve isomorphisms.

(4) $(\Leftarrow)$ is obvious. For $(\Rightarrow)$, we may assume that $\mathbb{K}$ is a linear suborder of $\mathbb{L}$ that is strictly bounded above by $l_0 \in \mathbb{L}$. Note that $G(\mathbb{K}) \prec G(\mathbb{L}) \prec G(\mathbb{L})$. So every ordinal of $G(\mathbb{K})$ is an ordinal of $G(L_{\mathcal{L}, l_0})$, and by (3), every ordinal of $G(L_{\mathcal{L}, l_0})$ is an ordinal of $G(\mathbb{L})$ below $\omega^\mathcal{A}$.

(5) We may assume that $\mathbb{L} \subseteq \mathcal{L}$. Suppose that $L \setminus K$ has no least element. Let $\alpha \in \text{Ord}^G(\mathcal{L}) \setminus \text{Ord}^G(\mathcal{K})$. Then $G(\mathbb{L}) \models \alpha = f(c_1, \ldots, c_m)$, for some $n \in \mathbb{N}$ and $l_1 < \cdots < l_n \in \mathbb{L}$. Let $1 \leq n^0 \leq n$ be the least natural number such that there is $l \in L \setminus K$ with $l < l_{n^0}$. Let $l^* \in L \setminus K$ witness this for $n^0$. To show that $G(\mathbb{L}) \models l^* < \alpha$, it suffices to show that

$$\{ \langle \xi_1, \ldots, \xi_{n^0-1}, \xi^*, \xi_{n^0}, \ldots, \xi_n \rangle \mid \xi^* < f(\xi_1, \ldots, \xi_n) \} \in \mathcal{U}^n+1. $$

Suppose not. Then

$$\{ \langle \xi_1, \ldots, \xi_{n^0-1}, \xi^*, \xi_{n^0}, \ldots, \xi_n \rangle \mid \xi^* \geq f(\xi_1, \ldots, \xi_n) \} \in \mathcal{U}^n+1, $$

so by completeness

$$\{ \langle \xi_1, \ldots, \xi_{n^0-1} \rangle \mid \exists \xi \{ \langle \xi_{n^0}, \ldots, \xi_n \rangle \mid \xi = f(\xi_1, \ldots, \xi_n) \} \in \mathcal{U}^{n-n^0+1} \} \in \mathcal{U}^{n-1}. $$

Hence, by iterability, we can code a function $f' : \text{Ord}^\mathcal{M}^{n^0-1} \to \text{Ord}^\mathcal{M}$ by the class

$$\{ \langle \xi_1, \ldots, \xi_{n^0-1}, \xi \rangle \mid \{ \langle \xi_{n^0}, \ldots, \xi_n \rangle \mid \xi = f(\xi_1, \ldots, \xi_n) \} \in \mathcal{U}^{n-n^0+1} \} \in \mathcal{A}. $$

32
and $\mathcal{G}(\mathcal{L}) \models f'((c_1,\ldots,c_{n+1})) = \alpha$. But this means that $\alpha \in \mathcal{G}(\mathcal{K})$, contradicting assumption.

$\Box$ (⇒) is obvious. For (⇐), assume that $i : \mathbb{K} \to \mathbb{L}$ is an equalizer of $j,j' : \mathbb{L} \to \mathbb{L}'$, i.e. we may assume that $\mathbb{K}$ is the linear suborder of $\mathbb{L}$ on $\{l \in \mathbb{L} \mid j(l) = j'(l)\}$. It suffices to show that for all elements $x$ of $\mathcal{G}(\mathcal{L})$, we have $\mathcal{G}(j)(x) = \mathcal{G}(j')(x) \iff x \in \mathcal{G}(\mathbb{K})$. (⇐) is obvious. For (⇒), suppose that $a \in \mathcal{G}(\mathcal{L}) \setminus \mathcal{G}(\mathbb{K})$. Let $n^*$ be the least natural number such that $\mathcal{G}(\mathcal{L}) \models a = f(c_1,\ldots,c_{n+1})$, for some $f \in A$ and $l_1 < \cdots < l_{n^*} \in \mathbb{L}$. Suppose towards a contradiction that $\mathcal{G}(\mathcal{L}) \models f(c_{j(l_1)},\ldots,c_{j(l_{n^*})}) = f(c_{j'(l_1)},\ldots,c_{j'(l_{n^*})})$. Since $\mathcal{U}$ is $(\mathcal{M},A)$-canonically Ramsey, since $f$ is coded in $A$ and since there is a bijection between the universe and the ordinals coded in $A$, there is $H \in \mathcal{U}$ and $S \subseteq \{1,\ldots,n^*\}$, such that for any $\alpha_1 < \cdots < \alpha_{n^*}$ and $\beta_1 < \cdots < \beta_{n^*}$ in $H$,

$$f(\alpha_1,\ldots,\alpha_{n^*}) = f(\beta_1,\ldots,\beta_{n^*}) \iff \forall m \in S, \alpha_m = \beta_m.$$ 

Since $a \not\in \mathcal{G}(\mathbb{K})$, there is $1 \leq n^* \leq n^*$, such that $l_{n^*} \in \mathbb{L} \setminus \mathbb{K}$ and consequently $j(l_{n^*}) \neq j'(l_{n^*})$. So since $f(c_{j(l_1)},\ldots,c_{j(l_{n^*})}) = f(c_{j'(l_1)},\ldots,c_{j'(l_{n^*})})$, we have $n^* \not\in S$. Note that $f' : (\text{Ord}^\mathcal{M})^{n^*-1} \to \mathcal{M}$, defined by

$$f'(\alpha_1,\ldots,\alpha_{n^*-1},\alpha_{n^*+1},\ldots,\alpha_{n^*}) =$$

$$f(\alpha_1,\ldots,\alpha_{n^*-1},\alpha_{n^*+1}+1,\alpha_{n^*+1},\ldots,\alpha_{n^*}),$$

is coded in $A$; and by $n^* \not\in S$,

$$f(\alpha_1,\ldots,\alpha_{n^*-1},\alpha_{n^*+1}+1,\alpha_{n^*+1},\ldots,\alpha_{n^*}) = f(\alpha_1,\ldots,\alpha_{n^*})$$

for all $\alpha_1 < \cdots < \alpha_{n^*} \in H$. Since $H \in \mathcal{U}$, it follows that

$$\mathcal{G}(\mathcal{L}) \models a = f'(c_1,\ldots,c_{n^*-1},c_{n^*+1},\ldots,c_{n+1}),$$

contradicting minimality of $n^*$.

$\Box$ (⇐) is obvious. For (⇒), let $\alpha$ be an arbitrary ordinal in $\mathcal{G}(\mathbb{K})$ not in $\mathcal{M}$. Let $k^*$ be the least element of $\mathbb{K}$, such that $\mathcal{G}(\mathbb{K}) \models \alpha = f(c_{k_1},\ldots,c_{k_n})$, where $f \in A$, $n \in \mathbb{N}$ and $k_1 < \cdots < k_n = k^* \in \mathbb{K}$. Note that $i'(\alpha)$ is in $\mathcal{G}(\mathcal{L}|_{\mathcal{L}'(k^*)})$ and that $i(\alpha)$ is in $\mathcal{G}(\mathcal{L}|_{\mathcal{L}'(k^*)})$. On the other hand, since $i(k^*) < i'(k^*)$, we have by minimality of $k^*$ that $i'(\alpha)$ is not in $\mathcal{G}(\mathcal{L}|_{\mathcal{L}'(k^*)})$. So by $\Box$ and $\Box$, $\mathcal{G}(\mathbb{L}) \models i(\alpha) < i'(\alpha)$. 

As seen in the proofs of the Corollaries below, this theorem is quite powerful when applied to the set of rational numbers $\mathbb{Q}$, with the usual ordering $<_{\mathbb{Q}}$. For any structure $\mathbb{K}$, and $S \subseteq \mathcal{K}$, we define $\text{End}_S(\mathbb{K})$ as the monoid of endomorphisms of $\mathbb{K}$ that fix $S$ pointwise, and we define $\text{Aut}_S(\mathbb{K})$ as the group of automorphisms of $\mathbb{K}$ that fix $S$ pointwise.

**Corollary 8.7.** If $\mathcal{M} \models \text{ZFC}$ expands to a countable model $(\mathcal{M},A)$ of GBC+ “Ord is weakly compact”, then there is $\mathcal{M} \prec^{\text{rank-cut}} \mathcal{N}$, such that $\text{SSy}_\mathcal{M}(\mathcal{N}) = (\mathcal{M},A)$, and such that for any countable linear order $\mathcal{L}$, there is an embedding of $\text{End}(\mathcal{L})$ into $\text{End}_{\mathcal{M}}(\mathcal{N})$. Moreover, this embedding sends every automorphism of $\mathcal{L}$ to an automorphism of $\mathcal{N}$, and sends every countable self-embedding of $\mathcal{L}$ to a self-embedding of $\mathcal{N}$ that is contractive on $\text{Ord}^\mathcal{N} \setminus \mathcal{M}$, and whose fixed-point set is $\mathcal{M}$.

**Proof.** Since $(\mathcal{M},A)$ is countable, Lemma 8.1 tells us that there is an $(\mathcal{M},A)$-generic ultrafilter $\mathcal{U}$. Let $\mathcal{N} = \mathcal{G}_{\mathcal{U},(\mathcal{M},A)}(\mathbb{Q})$. By Theorem 8.6 $\Box$, $\Box$, and $\Box$, $\mathcal{M} \prec^{\text{rank-cut}} \mathcal{N}$ and $\text{SSy}_\mathcal{M}(\mathcal{N}) = (\mathcal{M},A)$. By Theorem 8.6 $\Box$ and $\Box$, there is an embedding of $\text{End}(\mathbb{Q})$ into $\text{End}_{\mathcal{M}}(\mathcal{N})$. Moreover, it is well-known that for any countable linear order $\mathcal{L}$, there is an embedding of $\text{End}(\mathcal{L})$ into $\text{End}(\mathbb{Q})$. Composing these two embeddings gives the result. The last sentence in the statement follows from Theorem 8.6 $\Box$, $\Box$, $\Box$, and $\Box$. $\Box$
Lemma 8.8. For any $q \in \mathbb{Q}$, there is an initial topless contractive self-embedding of the usual linear order on $\mathbb{Q}$ that is strictly bounded by $q$.

Proof. It suffices to show that there is an initial topless contractive self-embedding of $\mathbb{Q}$, because by toplessness that would be bounded by some $q' \in \mathbb{Q}$ and we can compose it with the self-embedding $(x \mapsto x - |q' - q|)$ to obtain an initial topless contractive self-embedding bounded by $q$. Thus, we proceed to show that the usual linear order on $\mathbb{Q}$ can be expanded to a model of the following theory $T$, in the language of a binary relation $<$ and a unary function $f$:

- $<$ is a dense linear order without endpoints;
- $\forall x,y.(x < y \leftrightarrow f(x) < f(y))$;
- $\forall x,y.(x < f(y) \rightarrow \exists z.f(z) = x)$;
- $\exists y.\forall x.f(x) < y$;
- $\forall y.((\forall x.f(x) < y) \rightarrow \exists y'.(y' < y \land \forall x.f(x) < y'))$;
- $\forall x.f(x) < x$.

Let $R$ be the expansion of the order of the punctured reals $\mathbb{R} \setminus \{0\}$ inherited from the usual order of $\mathbb{R}$, interpreting $f$ by the function $f^R : \mathbb{R} \setminus \{0\} \rightarrow \mathbb{R} \setminus \{0\}$, defined by $f^R(x) = -2^{-x}$, for all $x \in \mathbb{R} \setminus \{0\}$. Note that $R \models T$. Now by the Downward Löwenheim-Skolem Theorem, there is a countable model $\mathbb{Q}$ of $T$. Since every countable dense linear order without endpoints is isomorphic to $(\mathbb{Q}, <_{\mathbb{Q}})$, it follows that $f^\mathbb{Q}$ induces an initial topless contractive self-embedding of $\mathbb{Q}$. $\square$

Corollary 8.9. Suppose that $M \models \text{ZFC}$ expands to a countable model $(M, \mathcal{A})$ of $\text{GBC} + \text{"Ord is weakly compact"}$. Then there is a model $M \models \text{rank-cut } N$, with $\text{SSy}_M(N) = (M, \mathcal{A})$, such that for any $\nu \in \text{Ord}^N \setminus M$, there is a rank-initial topless elementary self-embedding $j$ of $N$, which is contractive on $\text{Ord}^N \setminus M$, bounded by $\nu$, and satisfies $M \models \text{Fix}(j)$.

Proof. Let $\mathcal{U}$ be an $(M, \mathcal{A})$-generic ultrafilter, and let $N$ be the model $G_{M, (M, \mathcal{A})}(\mathbb{Q})$. As in Corollary 8.8, $M \models \text{rank-cut } N$ and $\text{SSy}_M(N) = (M, \mathcal{A})$. Let $\nu \in \text{Ord}^N \setminus M$. By Theorem 8.8 [1], there is a $q \in \mathbb{Q}$, such that $N \models c_q < \nu$. Using Lemma 8.8, let $j$ be an initial topless contractive self-embedding of $\mathbb{Q}$ that is strictly bounded by $q$. Let $j = G(j)$. The result now follows from Theorem 8.8. By [1], $j$ is an elementary embedding; by [1], $j$ is rank-initial; by [1], $j$ is bounded by $\nu$; by toplessness of $j$ and by [1] applied to $N \setminus G(j(\mathbb{Q}))$, $j$ is topless; by [1], $j$ is contractive on $N \setminus M$; and by [1], $M = \text{Fix}(j)$. $\square$

9 Geometric results

Theorem 9.1 (Kirby-Paris-style). Let $M \models \text{KP} + \text{Choice}$ be countable and let $S \leq \text{rank-cut } M$. The following are equivalent:

(a) $S$ is a strong rank-cut in $M$ and $\omega^M \in S$.

(b) $\text{SSy}_S(M) \models \text{GBC + "Ord is weakly compact"}$.

Proof. The two directions are proved as Lemmata 9.3 and 9.4 below. $\square$

Lemma 9.2. Let $M \models \text{KP} + \text{Choice}$, let $S$ be a strongly topless rank-initial substructure of $M$ and let us write $\text{SSy}_S(M)$ as $(S, \mathcal{A})$. For any $\phi(\vec{x}, \vec{y}) \in L^1$ and for any $\vec{A} \in \mathcal{A}$, there is a formula $\theta_{\phi}(\vec{x}, \vec{y}) \in \Delta^S_2 \subseteq L^0$ and parameters $\vec{p} \in M$, such that for all $\vec{s} \in S$,

$$(S, \mathcal{A}) \models \phi(\vec{s}, \vec{A}) \iff M \models \theta_{\phi}(\vec{s}, \vec{p}).$$
Proof. We construct \( \theta_\phi \) recursively on the structure of \( \phi \). Let \( \vec{A} \in \mathcal{A} \) be arbitrary and let \( \vec{a} \) be a tuple of codes in \( \mathcal{M} \) for \( \vec{A} \). In the base cases, given a coordinate \( A \) in \( \vec{A} \) and its code \( a \) in \( \vec{a} \), put:

\[
\begin{align*}
\theta_{x=y} & \equiv x = y, \\
\theta_{x \in y} & \equiv x \in y, \\
\theta_{x \in A} & \equiv x \in a.
\end{align*}
\]

It is clear that the result holds in the first two cases, and also in the third case since \( a \) codes \( A \).

Assume inductively that the result holds for \( \phi(\vec{x}, \vec{Y}) \), \( \psi(\vec{x}, \vec{Y}) \in \mathcal{L}^1 \) and \( \theta_\phi(\vec{x}, \vec{y}), \theta_\psi(\vec{x}, \vec{y}) \in \Delta^0_\alpha \), and put:

\[
\begin{align*}
\theta_{\neg \phi} & \equiv \neg \theta_\phi, \\
\theta_{\phi \lor \psi} & \equiv \theta_\phi \lor \theta_\psi, \\
\theta_{\exists x. \phi} & \equiv \exists x. \theta_\phi,
\end{align*}
\]

where \( b \in \mathcal{M} \) is next to be constructed. But before doing so, note that the result holds for the first two cases, simply because the connectives commute with \( \models \).

Let us write \( \vec{x} \) as \( x, \vec{z} \), and let \( k = \text{arity}(\vec{z}) \). Since \( S \) is bounded in \( \mathcal{M} \models \text{Infinity} \), there is a limit \( \mu \in \text{Ord}^\mathcal{M} \setminus S \). Therefore, by letting \( d = V^\mathcal{M}_\mu \), we obtain \( d \in \mathcal{M} \), \( S \subseteq d^\mathcal{M} \), and \( \mathcal{M} \models d^\mathcal{M} \subseteq d \). Working in \( \mathcal{M} \), by Choice and \( \Delta^0_\alpha \)-Separation, there is a function \( f : d \rightarrow d \), such that for all \( \vec{t} \in d^k \),

\[
\exists x \in d. \theta_\phi(x, \vec{t}, \vec{a}) \Leftrightarrow f(\vec{t}) \in \{ u \in d \mid \theta_\phi(u, \vec{t}, \vec{a}) \} \Leftrightarrow \theta_\phi(f(\vec{t}), \vec{t}, \vec{a}). \quad (\dagger)
\]

By strong toplessness and rank-initiality, there is \( \beta \in \text{Ord}^\mathcal{M} \setminus S \) such that for all \( s \in S \),

\[
f(s) \in S \Leftrightarrow \text{rank}(f(s)) < \beta. \quad (\ddagger)
\]

Put \( b = V^\mathcal{M}_\beta \). Note that by toplessness, \( S \) is closed under ordered pair. Putting \((\dagger)\) and \((\ddagger)\) together, we have that, for all \( \vec{s} \in S \),

\[
\mathcal{M} \models \exists x \in b. \theta_\phi(x, \vec{s}, \vec{a}) \Leftrightarrow \exists s_0 \in S. \mathcal{M} \models \theta_\phi(s_0, \vec{s}, \vec{a}),
\]

and by induction hypothesis,

\[
\exists s_0 \in S. \mathcal{M} \models \theta_\phi(s_0, \vec{s}, \vec{a}) \Leftrightarrow \exists s_0 \in S. (S, A) \models \phi(s_0, \vec{s}, \vec{A}) \Leftrightarrow (S, A) \models \exists x. \phi(x, \vec{s}, \vec{A}).
\]

Putting these equivalences together yields the desired result for \( \exists x. \phi \). The parameters \( \vec{p} \) appearing in \( \theta_{\exists x. \phi} \) are \( b \) together with \( \vec{a} \). \( \square \)

Lemma 9.3. Let \( \mathcal{M} \models \text{KP}^P + \text{Choice} \). If \( S \) is strong rank-cut in \( \mathcal{M} \) and \( \omega^\mathcal{M} \subseteq S \), then \( \text{SSy}_S(\mathcal{M}) \models \text{GBC} + \text{"Ord is weakly compact".} \)

Proof. Let us write \( \text{SSy}_S(\mathcal{M}) \) as \( (S, A) \). By toplessness and rank-initiality, there is \( d \in \mathcal{M} \) such that \( d^\mathcal{M} \supseteq S \).

\[ (S, A) \models \text{Class Extensionality, Pair, Union, Powerset, Infinity are inherited from } \mathcal{M}, \text{ because } \omega^\mathcal{M} \subseteq S \text{ and for any } \alpha \in \text{Ord}^S, \alpha + \mathcal{M} \cdot 2 \in S \text{ by toplessness, and } \mathcal{M} \cap \mathcal{M} \models S \text{ by rank-initiality.} \]

\[ (S, A) \models \text{Class Foundation: Let } A \in \mathcal{A} \text{ such that } (S, A) \models A \neq \emptyset. \text{ Let } a \text{ be a code for } A \text{ in } \mathcal{M}. \text{ By } \Pi^1_0 \text{-Foundation, there is an } c \in \mathcal{M} \text{-minimal element } m \in A. \text{ Since } A \text{ is non-empty, we have by rank-initiality that } m \in S. \text{ If there were } a \in S \text{ such that } (S, A) \models a \in m \cap A, \text{ then} \]

35
Then we have for all $\xi \mu \in \mathcal{M}$, by Overspill, there is $\theta_{\phi} \in \Delta_0^\mathcal{M}$, and let $\mathcal{A} \in \mathcal{M}$. By Lemma 9.2 there are $\theta_{\phi} \in \Delta_0^\mathcal{M}$ and $\vec{a} \in \mathcal{M}$, such that for all $s \in S$, 

$$(\mathcal{S}, \mathcal{A}) \models \phi(s, \vec{A}) \iff \mathcal{M} \models \theta_{\phi}(s, \vec{a}).$$

Working in $\mathcal{M}$, let $c = \{ t \in d \mid \theta_{\phi}(t, \vec{a}) \}$. Let $C \in \mathcal{A}$ be the class coded by $c$. It follows that 

$$\mathcal{S} \models \forall x. (x \in c \leftrightarrow \phi(x, \vec{A})).$$

$$(\mathcal{S}, \mathcal{A}) \models \text{Extended Separation}: \text{Simply observe that if } s \in S, \vec{A} \in \mathcal{A} \text{ and } \phi(x, \vec{Y}) \in \mathcal{L}_1, \text{ in which all variables of sort Class are free, and let } \vec{A} \in \mathcal{A}. \text{ By Lemma 9.2 there are } \theta_{\phi} \in \Delta_0^\mathcal{M} \text{ and } \vec{a} \in \mathcal{M}, \text{ such that for all } s \in S,$$

$$\mathcal{S} = \text{Global Choice:} \text{ By Choice in } \mathcal{M}, \text{ there is a choice function } f \text{ on } (d \setminus \{ \emptyset \})^\mathcal{M}. \text{ Note that } f \text{ codes a global choice function } F \in \mathcal{A} \text{ on } (V \setminus \{ \emptyset \})^{(\mathcal{M}, \mathcal{A})} \in \mathcal{A}.$$

$$(\mathcal{S}, \mathcal{A}) \models \text{Class Comprehension:} \text{ Let } \phi(x, \vec{Y}) \in \mathcal{L}_1, \text{ in which all variables of sort Class are free, and let } \vec{A} \in \mathcal{A}. \text{ By Lemma 9.2 there are } \theta_{\phi} \in \Delta_0^\mathcal{M} \text{ and } \vec{a} \in \mathcal{M}, \text{ such that for all } s \in S,$$

$$\mathcal{S} = \text{Class Replacement:} \text{ Let } F \in \mathcal{A} \text{ be a class function such that } \text{dom}(F) \in S, \text{ and let } f \text{ be a code in } \mathcal{M} \text{ for } F. \text{ In } \mathcal{M}, \text{ using } \text{dom}(F) \text{ and } f \text{ as parameters, we can construct a function } f' \text{ such that}$$

$$\text{dom}(f'_\mathcal{M}) = d \supseteq S,$$

$$\mathcal{M} \models \forall x. (x \in \text{dom}(F). ((x \in \text{dom}(F) \rightarrow f'(x) = f(x)) \land (x \notin \text{dom}(F) \rightarrow f'(x) = 0)).$$

Note that $f'_\mathcal{M} \upharpoonright S \subseteq S$. Suppose that 

$$(\mathcal{S}, \mathcal{A}) \models \exists x. (x \in \text{dom}(F). \text{rank}(F(x)) > \xi).$$

Then we have for all $\xi \in \text{Ord}^S$ that 

$$\mathcal{M} \models \exists x. (x \in \text{dom}(F). \text{rank}(d) > \text{rank}(f'(x)) > \xi).$$

So by Overspill, there is $\mu \in \text{Ord}^M \setminus S$ such that 

$$\mathcal{M} \models \exists x. (x \in \text{dom}(F). \text{rank}(d) > \text{rank}(f'(x)) > \mu).$$

But this contradicts that $f'_\mathcal{M} \upharpoonright S \subseteq S$. Therefore, 

$$(\mathcal{S}, \mathcal{A}) \models \exists x. (x \in \text{dom}(F). \text{rank}(F(x)) < \xi).$$

Now it follows by Extended Separation that image$^{(\mathcal{S}, \mathcal{A})}(F) \in S$.

$$(\mathcal{S}, \mathcal{A}) \models \text{“Ord is weakly compact”:} \text{ Let } \mathcal{T} \text{ be a binary tree of height } \text{Ord in } S, \text{ coded in } \mathcal{M} \text{ by } \tau \in \mathcal{M} \setminus S. \text{ Note that for all } \zeta \in \text{Ord}^S, \tau_\zeta \text{ is a binary tree of height } \zeta. \text{ So by } \Delta_0^\mathcal{M}-\text{Overspill}, \text{ there is } \mu \in \text{Ord}^\mathcal{M} \setminus S, \text{ such that } \tau_\mu \text{ is a binary tree of height } \mu. \text{ Let } f \in \mathcal{M} \tau_\mu \text{ such that } \text{dom}(f) \in \text{Ord}^\mathcal{M} \setminus S. \text{ Let } F \in \mathcal{A} \text{ be the class coded by } f. \text{ Since } S \text{ is rank-initial in } \mathcal{M}, \text{ we have for each } \zeta \in \text{Ord}^S, \text{ that } F(\mathcal{S}, \mathcal{A})(\zeta) = f(\mathcal{M} \upharpoonright \zeta). \text{ It follows that } F \text{ is rank-initial in } \mathcal{M}. \square$$

Lemma 9.4. Let $\mathcal{M} \models \text{KP}^\mathcal{P} + \Sigma_1^\mathcal{P}$-Separation be countable and non-standard, and let $S$ be a $\Sigma_1^\mathcal{P}$-elementary rank-cut of $\mathcal{M}$, such that 

$$\text{SSy}_S(\mathcal{M}) \models \text{GBC + “Ord is weakly compact”}.$$
Then there is a structure $\mathcal{N} \succ S$, and a self-embedding $i : \mathcal{N} \rightarrow \mathcal{N}$, such that $\text{Fix}(i) = S$, $i$ is contractive on $\mathcal{N} \setminus S$, and

$$S <_{\text{rank-cut}} i(\mathcal{M}) <_{\text{rank-cut}} i(\mathcal{N}) <_{\text{rank-cut}} \mathcal{M} <_{\text{rank-cut}} \mathcal{N}.$$  

Proof. Let us write $SSy_\varnothing(\mathcal{M})$ as $(\mathcal{S}, A)$. Since

$$(\mathcal{S}, A) \models \text{GBC + "Ord is weakly compact"},$$

we can apply Corollary 8.9 to obtain a model $\mathcal{N}$, such that $S <_{\text{rank}} \mathcal{N}$ and for each $\nu \in \text{Ord}^{\mathcal{N}} \setminus S$, there is a topless rank-initial self-embedding $i_\nu$ of $\mathcal{N}$, which is contractive on $\mathcal{N} \setminus S$ and which satisfies image($i_\nu$) $\subseteq N_\nu$ and $\text{Fix}(i_\nu) = S$.

Since $S \preceq M$ and $S \preceq \mathcal{N}$, we have $\text{Th}_{\Sigma^P, S}(M) = \text{Th}_{\Sigma^P, S}(\mathcal{N})$. So by Corollary 7.7, there is a topless rank-initial embedding $j : \mathcal{M} \rightarrow \mathcal{N}$ which fixes $S$ pointwise. Identify $\mathcal{M}$, pointwise, with the image of this embedding, and pick $\mu \in \text{Ord}^{\mathcal{M}} \setminus S$. Let $i = i_\mu$. It now follows from Proposition 6.6 that $i(\mathcal{M}) <_{\text{rank-cut}} i(\mathcal{N})$, so

$$S <_{\text{rank-cut}} i(\mathcal{M}) <_{\text{rank-cut}} i(\mathcal{N}) <_{\text{rank-cut}} \mathcal{M} <_{\text{rank-cut}} \mathcal{N},$$

as desired. \qed

Theorem 9.5 (Bahrami-Enayat-style). Let $\mathcal{M} \models \text{KP}^P + \Sigma^P_1$-Separation + Choice be countable and non-standard, and let $S$ be a proper rank-initial substructure of $\mathcal{M}$. The following are equivalent:

(a) $S = \text{Fix}(i)$, for some self-embedding $i : \mathcal{M} \rightarrow \mathcal{M}$.

(b) $S$ is a $\Sigma^P_1$-elementary strong rank-cut of $\mathcal{M}$.

Proof. (b) $\Rightarrow$ (a): It follows from Lemma 6.17 that $S \preceq_\Sigma \mathcal{M}$. Next we observe that $S$ is topless: It is assumed to be a proper substructure. If there were a least $\lambda \in \text{Ord}^{\mathcal{M}} \setminus S$, then by initiality of $i$ and $S \subseteq \text{Fix}(i)$, we would have $i(\lambda) = \lambda$, contradicting $S \supseteq \text{Fix}(i)$ and $\lambda \notin S$.

Let $\alpha, \beta \in \text{Ord}^{\mathcal{M}}$, with $\text{Ord}^{\mathcal{M}} \cap S \subseteq \alpha \cup \beta$, and let $f \in \mathcal{M}$ code a function from $\alpha$ to $\beta$ in $\mathcal{M}$. Note that $\text{Ord}^{\mathcal{M}} \cap S \subseteq \text{Fix}(i)$, and that $i(\alpha)$ codes a function from $i(\alpha)$ to $i(\beta)$ in $\mathcal{M}$. By $S = \text{Fix}(i)$, for all $\zeta \in \text{Ord}^{\mathcal{M}} \cap S$ we have

$$f(\zeta) \notin S \Rightarrow f(\zeta) \neq i(f)(\zeta).$$

We define a formula, with $f$ and $i(f)$ as parameters:

$$\phi(\xi) \equiv \text{Ord}(\xi) \wedge \forall \zeta < \xi. (f(\zeta) \neq i(f)(\zeta) \rightarrow f(\zeta) > \xi)$$

Note that $\phi$ is $\Pi^1_1$ and that $\mathcal{M} \models \phi(\zeta)$, for all $\zeta \in \text{Ord}^{\mathcal{M}} \cap S$. So by $\Pi^1_1$-Overspill and toplessness of $S$, there is $\mu \in \text{Ord}^{\mathcal{M}} \setminus S$ such that $\mathcal{M} \models \phi(\mu)$. Combining $\mathcal{M} \models \phi(\mu)$ with (†), we have for all $\zeta \in \text{Ord}^{\mathcal{M}} \cap S$ that

$$f(\zeta) \notin S \Rightarrow f(\zeta) > \mu.$$  

On the other hand, by $\mu \in \text{Ord}^{\mathcal{M}} \setminus S$, the converse is obvious. Hence, $S$ is strongly topless.

(a) $\Rightarrow$ (b): By Lemma 9.3 we can apply Lemma 9.3. The restriction $i|_\mathcal{M}$ of $i : N \rightarrow N$ (from Lemma 9.4) to $\mathcal{M}$, is a topless rank-initial self-embedding of $\mathcal{M}$ with fixed-point set $S$, which is contractive on $\mathcal{M} \setminus S$. \qed

37
Lemma 9.6. Let $\mathcal{M} \models \text{KP}^+ + \text{Choice}$ be countable and let $\mathcal{S}$ be a rank-cut of $\mathcal{M}$. If $\text{SSy}_{\mathcal{S}}(\mathcal{M}) \models \text{GBC} + \text{"Ord is weakly compact"}$, then $\mathcal{S}$ is a strong rank-cut of $\mathcal{M}$.

Proof. Write $\text{SSy}_{\mathcal{S}}(\mathcal{M})$ as $(\mathcal{S}, \mathcal{A})$. Let $\mathcal{S} \preceq \mathcal{N}$ be the elementary extension obtained from Corollary 8.9 with a topless rank-initial self-embedding $i$ that is contractive on $\mathcal{N} \setminus \mathcal{S}$. It follows from Theorem 9.5 that $\mathcal{S}$ is a strong rank-cut of $\mathcal{N}$.

Since $\mathcal{S}$ is rank-initial in $\mathcal{M}$, we have by Proposition 6.10 that $\text{Th}_{\text{Cut}}(\mathcal{S}) \subseteq \text{Th}_{\text{Cut}}(\mathcal{M})$. So since $\mathcal{S} \preceq \mathcal{N}$, we have $\text{Th}_{\text{Cut}}(\mathcal{N}) \subseteq \text{Th}_{\text{Cut}}(\mathcal{M})$, whence by Corollary 7.7 there is a topless rank-initial embedding $j : \mathcal{N} \to \mathcal{M}$ which fixes $\mathcal{S}$ pointwise. Now it follows from Proposition 6.6 that $\mathcal{S}$ is also a strong rank-cut of $\mathcal{M}$.

Lemma 9.7. Let $\mathcal{M}$ be a countable recursively saturated model of ZFC. If $\mathcal{S}$ is a strongly topless rank-initial elementary substructure of $\mathcal{M}$, then $\mathcal{S} \cong \mathcal{M}$, and a safe satisfaction relation on $\mathcal{S}$ is coded in $\text{SSy}_{\mathcal{S}}(\mathcal{M})$.

Proof. We start by showing that a safe satisfaction relation on $\mathcal{S}$ is coded in $\text{SSy}_{\mathcal{S}}(\mathcal{M})$. By the forward direction of Theorem 6.15, $\mathcal{M}$ is $\omega$-non-standard and admits a safe satisfaction relation $\text{Sat}^\mathcal{M}$. Put $\text{Sat}^\mathcal{S} = \text{Sat}^\mathcal{M} \cap \mathcal{S}$. Note that $\text{Sat}^\mathcal{S}$ is coded in $\mathcal{M}$, so the relation $\text{Sat}^\mathcal{S}$ is coded as a class in $\text{SSy}_{\mathcal{S}}(\mathcal{M})$. Since $\mathcal{S} \preceq \mathcal{M}$, we have $\omega^\mathcal{S} = \omega^\mathcal{M}$. So since $\mathcal{S}$ is rank-initial in $\mathcal{M}$ and $\mathcal{M}$ is $\omega$-non-standard, $\mathcal{S}$ is $\omega$-non-standard.

Since $\mathcal{S}$ is a strongly topless rank-initial elementary substructure of $\mathcal{M}$, we have by Lemma 9.3 that $\text{SSy}_{\mathcal{S}}(\mathcal{M}) \models \text{GBC}$. Therefore we have $(\mathcal{S}, \text{Sat}^\mathcal{S}) \models \text{ZFC}(\mathcal{S}_{\omega_1})$. To establish that $\text{Sat}^\mathcal{S}$ is a safe satisfaction relation on $\mathcal{S}$, it remains only to check that $(\mathcal{S}, \text{Sat}^\mathcal{S}) \models \sigma \in \Sigma_n[x], (\text{Sat}(\sigma, x) \leftrightarrow \text{Sat}_{\Sigma_n}(\sigma, x))$ and $(\mathcal{S}, \text{Sat}^\mathcal{S}) \models \forall \tau \in \Pi_n[x], \text{Sat}(\tau, x) \leftrightarrow \text{Sat}_{\Pi_n}(\tau, x))$, for each standard $n \in \mathbb{N}$. But this follows from that $\text{Sat}_{\Sigma_n}^\mathcal{S} = \text{Sat}_{\Sigma_n}^\mathcal{M} \cap \mathcal{S}^2$ and $\text{Sat}_{\Pi_n}^\mathcal{S} = \text{Sat}_{\Pi_n}^\mathcal{M} \cap \mathcal{S}^2$, for each standard $n \in \mathbb{N}$, which in turn follows from that $\mathcal{S} \preceq \mathcal{M}$.

By the backward direction of Theorem 6.15, it now follows that $\mathcal{S}$ is recursively saturated. Since recursively saturated models are $\omega$-non-standard, we have by Lemma 6.7 that $\text{WFP}(\mathcal{M})$ is $\omega$-topless in $\mathcal{M}$ and in $\mathcal{S}$. So by Theorem 7.14, $\mathcal{S} \cong \mathcal{M}$.

Theorem 9.8 (Kaye-Kossak-Kotlarski-style). Let $\mathcal{M} \models \text{ZFC} + V = \text{HOD}$ be countable and recursively saturated, and let $\mathcal{S}$ be a proper rank-initial substructure of $\mathcal{M}$. The following are equivalent:

(a) $\mathcal{S} = \text{Fix}(i)$, for some automorphism $i : \mathcal{M} \to \mathcal{M}$.

(b) $\mathcal{S}$ is a strongly topless elementary substructure of $\mathcal{M}$.

Proof. (a) $\Rightarrow$ (b): Since $\mathcal{M} \models V = \text{HOD}$, it has definable Skolem functions, whence Lemma 6.15 may be applied to the effect that $\mathcal{S} \preceq \mathcal{M}$. Strong toplessness of $\mathcal{S}$ follows from the forward direction of Theorem 9.5. By Lemma 9.7, we also have that $\mathcal{S} \cong \mathcal{M}$.

(b) $\Rightarrow$ (a): Let $(\mathcal{S}, \mathcal{A}) = \text{SSy}_{\mathcal{S}}(\mathcal{M})$. Since $\mathcal{S} \preceq \mathcal{M}$, we have $\omega^\mathcal{M} \in \mathcal{S}$. Now, by Lemma 9.3 $(\mathcal{S}, \mathcal{A}) \models \text{GBC} + \text{"Ord is weakly compact"}$. Thus, we may apply Theorem 8.5 (say with $L = Q$) to obtain a countable model $\mathcal{S} \preceq \mathcal{N}$ with an automorphism $j : \mathcal{N} \to \mathcal{S}$ such that $\text{Fix}(j) = \mathcal{S}$. By Lemma 9.7, $\mathcal{S}$ is strongly topless in $\mathcal{N}$.

Moreover, we have by Lemma 9.7 that $\mathcal{S}$ is recursively saturated with a safe satisfaction relation $\text{Sat}^\mathcal{S}$ coded in $\mathcal{A}$. By part (b) of Theorem 8.6, $\text{Sat}^\mathcal{S}$ corresponds to a safe satisfaction class $\text{Sat}^\mathcal{N}$ on $\mathcal{N}$. So by Theorem 6.15, $\mathcal{N}$ is recursively saturated. Since $\mathcal{S}$ is strongly topless in both $\mathcal{M}$ and $\mathcal{N}$, it now follows from Theorem 7.14 that there is an isomorphism $k \in \mathcal{M} \cong \mathcal{N}$ such that $i = k^{-1} \circ j \circ k$.
Theorem 9.9. Suppose that $\mathcal{M} \models \text{KP}^+ + \Sigma^P_1$-Separation+Choice is countable and non-standard. The following are equivalent:

(a) There is a strongly topless rank-initial self-embedding $i$ of $\mathcal{M}$.

(b) $\mathcal{M}$ expands to a model $(\mathcal{M}, A)$ of GBC+ “Ord is weakly compact”.

Proof. (a) $\Rightarrow$ (b): If $i$ is strongly topless and rank-initial, then by the Lemma 9.3 we have $\text{SSy}(i(\mathcal{M})) = GBC + \text{“Ord is weakly compact”}$. So since $\mathcal{M} \cong i(\mathcal{M})$, we have that $\mathcal{M}$ expands to a model of GBC+“Ord is weakly compact”.

(b) $\Rightarrow$ (a): Expand $\mathcal{M}$ to a countable model $(\mathcal{M}, A)$ of GBC+ “Ord is weakly compact”. Let $\mathcal{N} \succ \text{rank-cut} \mathcal{M}$ be a model obtained from Theorem 8.6 by putting $L$ to be a countable linear order without a least element, e.g. $\mathbb{Q}$. By Theorem 9.3 $\mathcal{M}$ is strongly topless in $\mathcal{N}$. Note that $\text{Th}(\mathcal{N}) = \text{Th}(\mathcal{M})$ and $\text{SSy}(\mathcal{N}) = \text{SSy}(\mathcal{M})$. So by Theorem 7.2 there is a rank-initial embedding $i : \mathcal{N} \to \mathcal{M}$. By Proposition 6.6 it now follows that $i(\mathcal{M})$ is strongly topless in $\mathcal{M}$. \qed
