Abstract In this paper, we propose a mosquito population suppression model which is composed of two sub-models switching each other. We assume that the releases of sterile mosquitoes are periodic and impulsive, only sexually active sterile mosquitoes play a role in the mosquito population suppression process, and the survival probability is density-dependent. For the release waiting period \(T\) and the release amount \(c\), we find three thresholds denoted by \(T^*, g^*,\) and \(c^*\) with \(c^* > g^*\). We show that the origin is a globally or locally asymptotically stable equilibrium when \(c \geq c^*\) and \(T \leq T^*\), or \(c \in (g^*, c^*)\) and \(T < T^*\). We prove that the model generates a unique globally asymptotically stable \(T\)-periodic solution when either \(c \in (g^*, c^*)\) and \(T = T^*\), or \(c > g^*\) and \(T > T^*\). Two numerical examples are provided to illustrate our theoretical results.

1 Introduction

To prevent and control the spread of mosquito-borne diseases such as malaria, dengue fever and Zika, effective and biologically safe approaches are to suppress the wild mosquito populations by using the sterile insect technique (SIT), the genetic approaches, and the Wolbachia-driven mosquito control technique, in which sterile mosquitoes, including irradiated and Wolbachia-infected male mosquitoes, are released into the wild to mate with wild female mosquitoes [1–6]. Various mathematical models have been developed to study the dynamics of mosquito populations with the release of sterile mosquitoes, we refer to [7–24] and references therein.

A wild female mosquito mating with a sterile mosquito will not be capable of producing offspring. Since the only function of the released males is to sterilize wild mosquitoes, only those sexually active sterile mosquitoes may play a role in the suppression process of wild mosquitoes. Based on these observations, the author in [17] first gave a novel modeling idea by treating the number of sterile mosquitoes as a given function instead of an independent variable satisfying a dynamical equation to explore the interactive dynamics of wild and sterile mosquitoes. This modeling technique mathematically reduces a planar system to a scalar differential equation, which makes mathematical analysis more tractable [18,19,25,26].

Due to the facts that mosquitoes have four metamorphic stages of development during their lifetime and the
intraspécific competition mainly occurs in the aquatic stages and thus in the birth process [27,28], the author in [29] proposed the following model:

\[
\frac{dw}{dt} = \frac{aw}{w + g}(1 - \xi w)w - \mu w, \\
\frac{dg}{dt} = B(\cdot) - \mu g,
\]

(1.1)

where \(w = w(t)\) and \(g = g(t)\) are the numbers of wild and sterile mosquitoes at time \(t\), respectively, \(a\) is the maximum number of survived offspring produced per mosquito, \(\frac{w}{w + g}\) is the mating probability between wild mosquitoes, \(\mu\) is the density-independent death rate of wild mosquitoes, \(\xi\) is the carrying capacity parameter such that \(1 - \xi w\) describes the density-dependent survival probability, and \(B(\cdot)\) is the release rate of the sterile mosquitoes.

Applying the modeling idea in [17], the authors in [30] discarded the second equation of system (1.1) by treating \(g(t)\) as a given nonnegative continuous function in advance, and formulated the following non-autonomous ordinary differential equation model:

\[
\frac{dw}{dt} = \frac{aw}{w + g}(1 - \xi w)w - \mu w.
\]

(1.2)

The strategy of periodic and impulsive releases of sterile mosquitoes has been proposed and well studied in [18,19,25,26,31], where only sexually active mosquitoes are included in the models. Let \(\bar{T}\) and \(T\) be the sexual lifespan of sterile mosquitoes and the waiting period between two consecutive releases, respectively. Accordingly, there are three possible release strategies: \(T < \bar{T}\), \(T = \bar{T}\), and \(T > \bar{T}\). For the release strategy of \(T = \bar{T}\), \(g(t) \equiv c\), model (1.3) becomes

\[
\frac{dw}{dt} = \frac{aw}{w + c}(1 - \xi w)w - \mu w.
\]

(1.3)

With the introduction of the release amount threshold

\[g^* = \frac{(a - \mu)^2}{4a\mu\xi},\]

the authors in [30] gave the following theorem.

**Theorem 1.1** For model (1.3), the following statements are true.

1. For the case when \(c \in (0, g^*)\), model (1.3) has three equilibria: the origin, denoted by \(w_0\), and two positive equilibria

\[
w_1(c) = \frac{A}{2} - \frac{\mu}{a\xi}(g^* - c) \quad \text{and} \quad w_2(c) = \frac{A}{2} + \frac{\mu}{a\xi}(g^* - c),
\]

where \(A = \frac{a - \mu}{a\xi}\). Furthermore, \(w_0\) and \(w_2(c)\) are both asymptotically stable, and \(w_1(c)\) is unstable.

2. For the case when \(c = g^*\), model (1.3) admits \(w_0\) and \(w^* = \frac{A}{2}\) as the equilibria. \(w_0\) is asymptotically stable, but \(w^*\) is semi-stable, stable from the right-side and unstable from the left-side.

3. For the case when \(c > g^*\), model (1.3) admits a unique equilibrium \(w_0\), which is globally asymptotically stable.

In this paper, we focus on the release strategy of \(T > \bar{T}\), which means that the sterile mosquitoes previously released have lost their mating competitiveness before the release of the next batch of sterile mosquitoes. We assume that a constant amount \(c\) of sterile mosquitoes are released at discrete time points \(T_i = iT, i = 0, 1, 2, \ldots\). During each \(T\)-periodic interval \([iT, (i + 1)T]\), the released mosquitoes at time \(T_i\) are sexually active for \(t \in [iT, iT + \bar{T})\), but inactive for \(t \in [iT + \bar{T}, (i + 1)T)\), \(i = 0, 1, 2, \ldots\). We find that \(g\) follows the following \(T\)-periodic and piecewise constant function:

\[g = \begin{cases} 
c, & \text{for } t \in [iT, iT + \bar{T}), \\
0, & \text{for } t \in [iT + \bar{T}, (i + 1)T).
\end{cases}
\]

Then, model (1.2) is divided into the following two sub-equations:

\[
\frac{dw}{dt} = \frac{aw^2}{w + c}(1 - \xi w) - \mu w,
\]

(1.4)

\[t \in [iT, iT + \bar{T}),
\]

and

\[
\frac{dw}{dt} = -a\xi w(w - A),
\]

(1.5)

\[t \in [iT + \bar{T}, (i + 1)T),
\]

which constantly switch each other, where \(i = 0, 1, 2, \ldots\). We assume \(a > \mu\) throughout this paper, so that the wild mosquito population without the interference of sterile mosquitoes is stabilized at the population size \(A\) [25,32,33].
Define \( T^* = \frac{a}{a - \mu} \) \( \bar{T} \) and \( c^* = \frac{a - \mu}{\mu \xi} \) as the release period threshold and the second release amount threshold, respectively. Obviously, we have \( c^* > g^* \). In this paper, we investigate the existence, uniqueness and stability of \( T \)-periodic solutions to model (1.4)–(1.5) by using Poincaré map method. These results may be helpful for optimal control of mosquito vector or mosquito-borne diseases as shown in [34]. In Sect. 2, we derive the Poincaré map formulation by solving (1.4)–(1.5) with initial value. We prove in Sect. 3 that the origin is globally asymptotically stable for the case when \( c \geq c^* \) and \( T \leq T^* \). The origin is locally asymptotically stable if and only if \( g^* < c < c^* \) and \( T < T^* \), and model (1.4)–(1.5) has a unique globally asymptotically stable \( T \)-periodic solution for the case when \( g^* < c < c^* \) and \( T = T^* \), or \( c > g^* \) and \( T > T^* \). Two numerical examples are also given to illustrate our theoretical results. Finally, in Sect. 4, we provide some discussions about the current and future work.

2 Preliminaries

It is clear to see that model (1.4)–(1.5) admits \( w_0 \) as the unique equilibrium. For any initial condition \((t_0, u_0) \in [0, \infty) \times (0, \infty)\), let \( w(t) = w(t; t_0, u_0) \) for \( t \geq t_0 \) denote the solution of model (1.4)–(1.5) with initial value \( w(t_0) = u_0 \). Then, \( w(t; t_0, u_0) \) is a continuous and piecewise differentiable function defined on \([t_0, \infty)\). When \( t_0 = 0 \), solution \( w(t; 0, u) \) follows Eq. (1.4) satisfying \( w(0) = u \) on \([0, \bar{T}]\), and then initiated from \( w(\bar{T}) = w(\bar{T}^-) \), the solution goes to \( w(T; 0, u) \) following Eq. (1.5) for \( t \in [\bar{T}, T) \). The solution can be described on the other \( T \)-periodic intervals in the same manner. According to the continuous and differentiable dependence of the solutions on the initial values to ordinary differential equations [35], we obtain that \( w(\bar{T}; 0, u) \) and \( w(T; 0, u) \) are both continuously differentiable with respect to \( u \). Furthermore, if \( w(T) = w(T; 0, u) = u \), then \( w(t) = w(t; 0, u) \) is a \( T \)-periodic solution of model (1.4)–(1.5). Thus, in order to find a \( T \)-periodic solution of model (1.4)–(1.5), we only need to find an initial value \( u > 0 \) such that \( w(T; 0, u) = u \). We write \( h(u) = w(T; 0, u) \)

\[
\tilde{h}(u) = w(\bar{T}; 0, u). \tag{2.1}
\]

Then, \( h(u) = w(T; \bar{T}, \tilde{h}(u)) \).

To obtain \( \tilde{h}(u) \) and \( h(u) \), we need to solve initial value problem (1.4) with \( w(0) = u \). Now, we assume \( c > g^* \). Equation (1.4) can be rewritten as:

\[
\frac{dw}{dt} = -a\xi w + \left( \frac{w^2}{2} + \frac{\mu c}{a\xi} \right),
\]

or, equivalently,

\[
-a\xi dt = \left( \frac{\alpha}{w} + \beta \left( \frac{w - A}{2} \right)^2 + b^2 \right) dw,
\]

which yields

\[
d \left\{ \ln \left[ w^a \left( \left( \frac{w - A}{2} \right)^2 + b^2 \right) \right] \right\} = -a\xi dt.
\]

where

\[
\alpha = \frac{a\xi}{\mu}, \quad \beta = -\frac{a\xi}{\mu}, \quad \gamma = \frac{a + \mu}{2\mu}, \quad b = \sqrt{\frac{\mu}{a\xi}(c - g^*)}.
\]

Integrating (2.2) from 0 to \( \bar{T} \), we obtain

\[
w^a(\bar{T}) \left( \left( \frac{w(\bar{T}) - A}{2} \right)^2 + b^2 \right)^\frac{\beta}{2} = \exp \left( \frac{\gamma}{b} \tan^{-1} \left( \frac{w(\bar{T}) - A}{2b} \right) \right) = w^a(0) \left( \left( \frac{w(0) - A}{2} \right)^2 + b^2 \right)^\frac{\beta}{2} \exp \left( \frac{\gamma}{b} \tan^{-1} \left( \frac{w(0) - A}{2b} \right) \right) e^{-a\xi \bar{T}},
\]

which yields, from (2.1),

\[
\tilde{h}^a(u) \left( \left( \tilde{h}(u) - \frac{A}{2} \right)^2 + b^2 \right)^\frac{\beta}{2} = \exp \left( \frac{\gamma}{b} \tan^{-1} \left( \frac{\tilde{h}(u) - A}{b} \right) \right) = u^a \left( \left( \frac{u - A}{2} \right)^2 + b^2 \right)^\frac{\beta}{2} \exp \left( \frac{\gamma}{b} \tan^{-1} \left( \frac{u - A}{2b} \right) \right) e^{-a\xi \bar{T}}. \tag{2.3}
\]
Now, we solve initial value problem (1.5) for \( t \in [\bar{T}, T) \) with \( w(\bar{T}) = w(T^{-}) = \bar{h}(u) \). It follows from (1.5) that
\[
d \left( \ln \left( \frac{w}{|A - w|} \right) \right) = a A \xi dt.
\]
Integrating (2.4) from \( \bar{T} \) to \( T \) yields
\[
\frac{w(T)}{A - w(T)} = \frac{w(\bar{T})}{A - w(\bar{T})} e^{a A \xi (T - \bar{T})},
\]
and thus, we get, from (2.1),
\[
\bar{h}(u) = \frac{m h(u)}{A - h(u)},
\]
where \( m = e^{-a A \xi (T - \bar{T})} \).

Define function sequences \( \{ h_n \} \) and \( \{ \bar{h}_n \} \) as follows:
\[
h_n(u) = w(nT; 0, u), \quad \bar{h}_n(u) = w(nT + \bar{T}; 0, u), \quad n = 0, 1, 2, \ldots
\]
We obtain, by induction,
\[
h_{n+1}(u) = w(T; 0, h_n(u)) = h(h_n(u)), \quad \bar{h}_n(u) = \bar{h}(h_n(u)), \quad n = 0, 1, 2, \ldots
\]
where
\[
h_0(u) = u, \quad \bar{h}_0(u) = w(\bar{T}; 0, u), \quad \text{and} \quad h_1(u) = h(u).
\]

By using a similar argument to that in [25], we can easily prove the next lemma.

**Lemma 2.1** For any given initial value \( u \), the following conclusions hold:

1. Sequences \( \{ h_n(u) \} \) and \( \{ \bar{h}_n(u) \} \) are both strictly increasing if and only if \( h(u) > u \).
2. \( h_n(u) \equiv u, n = 1, 2, 3, \ldots, \) if and only if \( h(u) = u \).

Hence, \( w(t) = w(t; 0, u) \) is a \( T \)-periodic solution of model (1.4)–(1.5).

3. Sequences \( \{ h_n(u) \} \) and \( \{ \bar{h}_n(u) \} \) are both strictly decreasing if and only if \( h(u) < u \).

Note that \( w(t) = A \) is a solution of the second equation of model (1.4)–(1.5), along with \( c > g^{*} \), we have \( h(u) < u \), for \( u \geq A \).

Thus, if there exists \( \delta \in (0, A) \) such that \( h(\delta) > \delta \), then model (1.4)–(1.5) has at least one \( T \)-periodic solution \( w(t; 0, u) \) with \( u \in (\delta, A) \) owing to the continuous differentiability of \( h(u) \).

Since \( \bar{h}(u) \to 0 \) as \( u \to 0 \), we obtain, from (2.3),
\[
\lim_{u \to 0} \frac{\bar{h}(u)}{u} = e^{-a A \xi \bar{T}} e^{-\mu \bar{T}}.
\]
Following from \( h(u) \to 0 \) as \( u \to 0 \), we have, from (2.5),
\[
\lim_{u \to 0} \frac{h(u)}{\bar{h}(u)} = \lim_{u \to 0} \frac{A - h(u)}{m(A - h(u))} = \frac{1}{m} e^{a A \xi (T - \bar{T})} = e^{(a - \mu)(T - \bar{T})}.
\]
Therefore, from (2.7) and (2.8), we have
\[
h'(0) = \lim_{u \to 0} \frac{h(u)}{u} = \lim_{u \to 0} \left( \frac{h(u)}{\bar{h}(u)} \cdot \frac{\bar{h}(u)}{u} \right) = e^{(a - \mu)(T - \bar{T})^*}.
\]
Hence, \( h'(0) > 1 \) implies that model (1.4)–(1.5) has at least one \( T \)-periodic solution.

## 3 Main results

In this section, we will present our main results by dividing the study into two cases: \( T \leq T^* \) and \( T > T^* \).

### 3.1 Release more often with \( T \leq T^* \)

In this subsection, we consider the case of \( T \leq T^* \). That is, we release sterile mosquitoes more often. Before presenting our first result, we give the following lemma.

**Lemma 3.1** Assume that \( c \geq c^* \) and \( T \leq T^* \). Then, we have
\[
h(u) < u, \quad \text{for} \quad u > 0.
\]

**Proof** By (2.6), to prove (3.1), we only need to prove
\[
h(u) < u, \quad \text{for} \quad u \in (0, A).
\]

We divide the proof of (3.2) into two cases: \( T = T^* \) and \( T < T^* \). For the case when \( T = T^* \), we let \( m = e^{-a A \xi \bar{T}} \). From (2.3) and (2.5), we have
\[
\left( \frac{h(u)}{u} \right)^\alpha = \left( \frac{h(u)}{h(u)} \cdot \tilde{h}(u) \right)^\alpha = \left( \frac{A - h(u)}{m(A - h(u))} \cdot \frac{\left( \frac{u}{2} - b \right)^2 + b^2}{\left( \frac{h(u)}{2} - b \right)^2 + b^2} \exp \left( \frac{\gamma}{b} \tan^{-1} \left( \frac{u - \frac{4}{2}}{b} \right) \right) \right) \alpha \exp \left( \frac{\gamma}{b} \tan^{-1} \left( \frac{u - \frac{4}{2}}{b} \right) \right) \alpha \exp \left( \frac{\gamma}{b} \tan^{-1} \left( \frac{h(u) - \frac{4}{2}}{b} \right) \right) \alpha \exp \left( \frac{\gamma}{b} \tan^{-1} \left( \frac{h(u) - \frac{4}{2}}{b} \right) \right) \alpha \exp \left( \frac{\gamma}{b} \tan^{-1} \left( \frac{h(u) - \frac{4}{2}}{b} \right) \right)
\]

Set
\[
Y(u) = \left( \frac{u}{2} - b \right)^2 + b^2 \exp \left( \frac{\gamma}{b} \tan^{-1} \left( \frac{u - \frac{4}{2}}{b} \right) \right)
\]
and
\[
H(u) = (A - u)^\alpha Y(u).
\]
Then, we get
\[
\left( \frac{h(u)}{u} \right)^\alpha = \left( \frac{A - h(u)}{A - h(u)} \right)^\alpha \cdot \left( \frac{A - u}{A - h(u)} \right)^\alpha \cdot \frac{Y(u)}{h(h(u))} = \left( \frac{A - h(u)}{A - u} \right)^\alpha \cdot \frac{H(u)}{h(h(u))}.
\]
(3.3)

To prove (3.2), it suffices to prove
\[
H(u) < H(h(u)), \quad \text{for} \quad u \in (0, A).
\]
(3.4)
By taking the derivative of \(H(u)\), we have
\[
H'(u) = \left( -\frac{\alpha}{A - u} + \frac{\beta \left( \frac{u}{2} - b \right) + \gamma}{\left( \frac{u}{2} - b \right)^2 + b^2} \right) H(u)
\]
\[
= \left( -\frac{\alpha}{A - u} + \frac{\alpha + \gamma}{u \left( \frac{u}{2} - b \right)^2 + b^2} \right) H(u)
\]
\[
= \frac{1}{A - u} \left( -\frac{\alpha A}{A - u} + \frac{\alpha + \gamma}{\left( \frac{u}{2} - b \right)^2 + b^2} \right) H(u)
\]
\[
= -\frac{\alpha (A - \tilde{u}) \left( u - \frac{4}{2} \right)}{\left( u - \frac{4}{2} \right)^2 + b^2} H(u),
\]
(3.5)
where
\[
\tilde{u} = \frac{c^* - c}{1 + A} \leq 0.
\]
(3.6)
Thus, we have \(H'(u) < 0\), for \(u \in (0, A)\). This proves that (3.4) holds since \(h(u) < u\). Hence, (3.2) is true for the case when \(T = T^*\).

For the case when \(T < T^*\), we get \(h'(0) = e^{(u - \mu)(T - T^*)} < 1\) from (2.9), which implies that there is \(u_0 \in (0, A)\) such that
\[
h(u) < u, \quad \text{for} \quad u \in (0, u_0).
\]
Now, we show that (3.2) is still true. To this end, we assume by contradiction that (3.2) is not true. Then, there exists \(u \in (0, u_0)\) such that
\[
h(u) = \tilde{u} \quad \text{and} \quad h'(u) \geq 1.
\]
(3.7)
Let
\[
P(u) = u^2 \left( \frac{u - A}{2} \right)^2 + b^2 \exp \left( \frac{\gamma}{b} \tan^{-1} \left( \frac{u - \frac{4}{2}}{b} \right) \right).
\]
Then, we obtain
\[
P'(u) = \left( u^2 \left( \frac{u - A}{2} \right)^2 + b^2 \right) \exp \left( \frac{\gamma}{b} \tan^{-1} \left( \frac{u - \frac{4}{2}}{b} \right) \right) P(u) = \frac{u + c}{u \left( \frac{u - A}{2} \right)^2 + b^2} P(u).
\]
(3.8)
From (2.3), we have
\[ P(\tilde{h}(u)) = P(u)e^{-a\xi\tilde{T}}, \tag{3.9} \]
which, by taking the derivative, yields
\[ P'(\tilde{h}(u))\tilde{h}'(u) = P'(u)e^{-a\xi\tilde{T}}, \]
which gives, by combining (3.8) with (3.9),
\[ \tilde{h}'(u) = \frac{\tilde{h}(u) \left( (\tilde{h}(u) - \frac{4}{2})^2 + b^2 \right) (u + c)}{u \left( (u - \frac{4}{2})^2 + b^2 \right) (\tilde{h}(u) + c)}. \tag{3.10} \]

Taking the derivative of both sides of (2.5) yields
\[ \frac{\tilde{h}'(u)}{(A - \tilde{h}(u))^2} = \frac{m h'(u)}{(A - h(u))^2}. \tag{3.11} \]
Substituting (2.5) and (3.10) into (3.11), we have
\[ h'(u) = \frac{h(u) (A - h(u)) \left( (\tilde{h}(u) - \frac{4}{2})^2 + b^2 \right) (u + c)}{u \left( (u - \frac{4}{2})^2 + b^2 \right) (\tilde{h}(u) + c)}. \tag{3.12} \]

From (2.5) again, we get
\[ A - \tilde{h}(u) = \frac{A(A - h(u))}{A - (1 - m)h(u)}, \]
\[ \tilde{h}(u) + c = \frac{c A + (m A - (1 - m) c) h(u)}{A - (1 - m)h(u)}, \]
\[ \tilde{h}(u) - 2 = \frac{A - (1 + m)h(u)}{A - (1 - m)h(u)}, \]
which lead to, by (3.12),
\[ h'(u) = \frac{h(u) \left[ \frac{4}{2} (A - (1 + m) h(u))^2 + b^2 (A - (1 - m) h(u))^2 \right] (u + c)}{A u \left( (u - \frac{4}{2})^2 + b^2 \right) \left[ c A + (m A - (1 - m) c) h(u) \right]}. \tag{3.13} \]

It follows from (3.7) that
\[ h'(\tilde{u}) = \frac{\left[ \frac{4}{2} (A - (1 + m) \tilde{u})^2 + b^2 (A - (1 - m) \tilde{u})^2 \right] (\tilde{u} + c)}{A \left( (\tilde{u} - \frac{4}{2})^2 + b^2 \right) \left[ c A + (m A - (1 - m) c) \tilde{u} \right]} \geq 1, \]
which yields
\[ B\tilde{u}^2 + C\tilde{u} + D \geq 0, \]
where
\[ B = \frac{a - m \mu}{a \xi}, \quad C = \frac{(1 - m) \epsilon \mu \xi - 2(a - \mu)}{a \xi^2}, \quad \text{and} \quad D = -\frac{\mu (c - c^*)}{a \xi}. \tag{3.14} \]

Let the quadratic polynomial \( Q(u) \) be defined as:
\[ Q(u) = Bu^2 + Cu + D. \tag{3.15} \]
Then, \( Q(\tilde{u}) \geq 0 \) and \( Q(u) \) is concave up since \( B > 0 \). Moreover, we find that \( Q(A) = -\frac{a - \mu + ac\xi}{a \xi^2} m \mu A < 0 \).
To sum up, we have
\[ Q(0) = D \leq 0, \quad Q(\tilde{u}) \geq 0, \quad \text{and} \quad Q(A) < 0, \]
which is impossible since \( 0 < \tilde{u} < A \). Hence, (3.2) is also true for the case when \( T < T^* \), and thus (3.1) is true. The proof is complete.

The following result shows that if the release amount \( c \geq c^* \), then the mosquito population will be eradicated eventually, which is guaranteed by the global asymptotical stability of \( w_0 \).

**Theorem 3.2** Assume that \( c \geq c^* \) and \( T \leq T^* \). Then, the origin \( w_0 \) is globally asymptotically stable.

**Proof** We first prove that \( w_0 \) is stable. It follows from (2.7) that we can select \( \epsilon_0 \in (0, \frac{4}{2}) \) such that \( h(u) > Mu \) for \( u \in (0, \epsilon_0) \), where \( M = \frac{\frac{4}{2} e^{-\mu T}}{2} \). For any \( 0 < \epsilon < \epsilon_0 \) and \( t_0 \geq 0 \), let \( \delta = \min \left\{ M \epsilon, \frac{mA \epsilon}{A - (1 - m)\epsilon} \right\} \),
we only need to prove that \( u_0 \in (0, \delta) \) implies
\[ w(t; t_0, u_0) < \epsilon, \quad \text{for} \quad t \geq t_0. \tag{3.16} \]

For convenience, we denote \( w(t) = w(t; t_0, u_0) \). Since model (1.4)–(1.5) is \( T \)-periodic, we may assume \( t_0 \in [0, T) \).
We now prove (3.16) by contradiction. If (3.16) does not hold, then there is some \( \tilde{t} > t_0 \) such that
\[ w(\tilde{t}) = \epsilon, \quad w(t) < \epsilon, \quad \text{for} \quad t \in [t_0, \tilde{t}). \tag{3.17} \]
Let \( p \) be a positive integer such that \( \bar{t} \in [pT, (p+1)T) \). Then, there are three possible cases to consider: (I) \( \bar{t} = pT \), (II) \( \bar{t} = pT + \bar{T} \), and (III) \( \bar{t} \in (pT, pT + \bar{T}) \cup (pT + \bar{T}, (p+1)T) \). Obviously, (II) is impossible since \( w(pT + \bar{T}) \) is the minimum of \( w(t) \) for \( t \in [pT, (p+1)T) \). Now, we show that (I) is impossible. In fact, if (I) holds, then either \( p = 1 \) or \( p > 1 \).

For the case when \( p = 1 \), there are two possible cases \( t_0 \in [0, \bar{T}] \) and \( t_0 \in (\bar{T}, T) \) to consider.

Assume \( t_0 \in [0, \bar{T}] \). Then, we have from (2.5),

\[
\frac{Amw(T)}{A - (1-m)w(T)} = \frac{Am\epsilon}{A - (1-m)\epsilon} \geq \delta,
\]

which yields \( w(t_0) \geq w(T) \geq \delta \), a contradiction to \( w(t_0) = u_0 \in (0, \delta) \).

Assume \( t_0 \in (\bar{T}, T) \). Then, we have, by integrating (2.4) from \( t_0 \) to \( \bar{T} \),

\[
\frac{w(t_0)}{A - w(t_0)} = \frac{m w(\bar{T})}{A - w(\bar{T})},
\]

which leads to

\[
w(t_0) = \frac{Am w(\bar{T})}{A - (1-m)w(\bar{T})} = \frac{Am\epsilon}{A - (1-m)\epsilon},
\]

where \( m = e^{-a(\bar{T}-t_0)} > m \). Since \( \frac{Am\epsilon}{A - (1-m)\epsilon} \) is strictly increasing with respect to \( x \in (0, 1) \), we obtain

\[
w(t_0) > \frac{Am\epsilon}{A - (1-m)\epsilon} \geq \delta,
\]

a contradiction again. This shows that (I) is impossible for the case when \( p = 1 \).

For the case when \( p > 1 \), we see that \( w(pT) = \epsilon > w((p-1)T) \) by the fact that \( t_0 < T \leq (p-1)T \).

Let \( u_1 = w((p-1)T) \). Then \( h(u_1) = w(T; 0, u_1) = w(pT) > u_1 \).

From (3.1), we have \( h(u_1) < u_1 \), a contradiction. This shows that (I) is impossible for the case when \( p > 1 \). Hence, (I) is impossible.

We next show that (II) is impossible as well. By (3.17), we have \( w'(\bar{t}) \geq 0 \), which excludes the situation of \( \bar{t} \in (pT, pT + \bar{T}) \). Thus, we need only to consider the case of \( \bar{t} \in (pT, (p+1)T) \).

From equation (1.5), we see that \( w(t) \) is strictly increasing for \( t \in (pT, (p+1)T) \), and hence \( w((p+1)T) > w(\bar{t}) = \epsilon > w(pT) \). From Lemma 2.1, we get \( h(u) > u \), which contradicts (3.1). Hence, (II) is also impossible and so (3.16) is true. This shows that \( w_0 \) is stable.

Finally, we prove that \( w_0 \) is globally attractive. For any \( t_0 \in [0, T) \) and \( u_0 > 0 \), we just need to show

\[
\lim_{t \to \infty} w(t) = \lim_{t \to \infty} w(t; t_0, u_0) = 0.
\]

Since \( w(t) \) reaches its maximum at \( nT \) for \( t \in [(n-1)T + \bar{T}, nT + \bar{T}] \), \( n = 2, 3, \ldots \), it suffices to prove that

\[
\lim_{n \to \infty} h_n(u) = \lim_{n \to \infty} w(nT) = \lim_{n \to \infty} w(nT; t_0, u_0) = 0. \tag{3.18}
\]

From (3.1) and Lemma 2.1, we see that sequence \( (h_n(u)) \) is strictly decreasing, so limit \( \lim_{n \to \infty} h_n(u) = q \geq 0 \) exists. It is easy to prove \( q = 0 \) due to the non-existence of periodic solution to model (1.4)–(1.5).

Hence, (3.18) is true and the proof is complete.

We then give a numerical example to illustrate our theoretical results in Theorem 3.2.

**Example 1** Let the parameters \( a, \mu, \xi \) and \( \bar{T} \) be given as follows:

\[
a = 2, \quad \mu = 0.05, \quad \xi = 0.001, \quad \text{and} \quad \bar{T} = 14. \tag{3.19}
\]

Then, \( g^* = 9506.25, c^* = 39,000, \) and \( T^* \approx 14.36 \). By taking \( c = 40,000 > c^* \) and \( T = 14.10 < T^* \), \( c = c^* \) and \( T = T^* \), and \( c = c^* \) and \( T = T^* \), respectively, the conditions of Theorem 3.2 are all satisfied and \( w_0 \) is globally asymptotically stable as shown in panels (A), (B), (C) and (D) of Fig. 1.

Theorem 3.2 tells us that the release strategy of \( c \geq c^* \) and \( T < T^* \) can eventually ensure the elimination of mosquitoes. The next theorem focuses on the situation when \( c \in (g^*, c^*) \).

**Theorem 3.3** Assume that \( g^* < c < c^* \). Then, the following two conclusions hold.

(1) If \( T = T^* \), then model (1.4)–(1.5) has a unique \( T \)-periodic solution, which is globally asymptotically stable.

(2) The origin is asymptotically stable if and only if \( T < T^* \).

**Proof** (1) Assume that \( T = T^* \). We need to show that model (1.4)–(1.5) has a unique \( T \)-periodic solution, which is globally asymptotically stable. From (3.6), we have \( \hat{u} < 0 \). Then, we have \( \hat{u} = \frac{c^* - c}{1+\alpha A} < A \) since \( c < c^* \). We first claim that

\[
h(u) > u, \quad \text{for} \quad u \in (0, \hat{u}). \tag{3.20}
\]
For given parameters in (3.19), the above four figures, which correspond to four kinds of sub-cases of the conditions \( c \geq c^* \) and \( T \leq T^* \), are used to support our theoretical results in Theorem 3.2.

From (3.3), we just need to show
\[
H(u) > H(\bar{h}(u)), \quad \text{for} \quad u \in (0, \bar{u}). \tag{3.21}
\]
From (3.5), we reach
\[
H'(u) > 0, \quad \text{for} \quad 0 < u < \bar{u}, \quad \text{and} \quad H'(u) < 0, \quad \text{for} \quad u \in (\bar{u}, A), \tag{3.22}
\]
which means that \( H(u) \) is strictly increasing for \( u \in (0, \bar{u}) \), and strictly decreasing for \( u \in (\bar{u}, A) \). Then, (3.21) holds as \( h(u) < u < \bar{u} \). Hence, (3.20) is true. Combining (2.6) with (3.20), we know that there must exist \( u_1 \in (\bar{u}, A) \) such that
\[
h(u_1) = u_1, \quad \text{and} \quad h(u) > u, \quad \text{for} \quad u \in (0, u_1).
\]
Thus, \( w(t; 0, u_1) \) is a \( T \)-periodic solution of model (1.4)–(1.5). This shows the existence of a \( T \)-periodic solution.

Now, we prove the uniqueness of \( T \)-periodic solutions of model (1.4)–(1.5) by contradiction. Assume that model (1.4)–(1.5) has another \( T \)-periodic solution. Then, there is some \( u_2 \in (u_1, A) \) such that \( h(u_2) = u_2 \) and \( h(u) < u \) for \( u \in (u_2, A) \). From (3.3), we have
\[
H(u_i) = H(\tilde{h}(u_i)), \quad i = 1, 2,
\]
which gives, along with (3.22) and the fact of \( \bar{u} < u_1 < u_2 < A \),
\[
\tilde{h}(u_2) \quad < \quad \bar{h}(u_1) \quad < \quad \bar{u}.
\]
Note that \( \tilde{h}(u) \) is strictly increasing, we have \( \tilde{h}(u_2) > \tilde{h}(u_1) \), which leads to a contradiction. Hence, model (1.4)–(1.5) admits \( w(t; 0, u_1) \) as its unique \( T \)-periodic solution.

To prove the global asymptotical stability of \( w(t; 0, u_1) \), we only need to prove \( w_0 \) is unstable. From (3.20)
and Lemma 2.1, we find that both \( \{ h_n(u) \} \) and \( \{ \tilde{h}_n(u) \} \) are strictly increasing for \( u \in (0, \tilde{u}) \), which shows that \( w_0 \) is unstable. Hence, the proof of (1) is complete.

(2) Assume that \( w_0 \) is asymptotically stable. We need to show \( T < T^* \). From (2.9), we have \( h'(0) = e^{(a-\mu)(T-T^*)} \). It suffices to verify \( h'(0) < 1 \). Assume by contradiction that \( h'(0) \geq 1 \). For case \( h'(0) > 1 \), there exists \( \delta^* > 0 \) small enough such that \( h(u) > u \) for \( u \in (0, \delta^*) \), which implies that, from Lemma 2.1, \( \{ h_n(u) \} \) is strictly increasing for \( u \in (0, \delta^*) \), and thus \( \lim_{n \to \infty} h_n(u) \neq 0 \), a contradiction to the asymptotical stability of \( w_0 \). Similarly, for case \( h'(0) = 1 \), we obtain \( T = T^* \), which yields a unique globally asymptotically stable \( T \)-periodic solution from the first conclusion of this theorem. Again, a contradiction to the asymptotical stability of \( w_0 \).

Next, we assume \( T < T^* \). We need to prove that \( w_0 \) is asymptotically stable. From (2.9), we see \( h'(0) = e^{(a-\mu)(T-T^*)} < 1 \), which means that there exists \( \delta_1 > 0 \) small enough, such that

\[
h(u) < u, \quad \text{for} \quad u \in (0, \delta_1).
\]

For any \( \epsilon \in \left( 0, \frac{\delta_1}{2} \right) \), let \( \delta = \min \left\{ \epsilon, \frac{mAe}{A - (1 - m)\epsilon} \right\} \). Then, by a similar argument to that of Theorem 3.2, we can prove that \( w_0 \) is asymptotically stable. The proof is finished.

For the critical release period \( T = T^* \), Theorem 3.3(1) shows that if \( g^* < c < c^* \), then mosquito population eradication is impossible due to the existence of a unique globally asymptotically stable \( T \)-periodic solution. To see this, we give a numerical example in the following to illustrate our theoretical results in Theorem 3.3, together with an observation on the existence of exactly two periodic solutions for some \( T < T^* \) and \( c \in (g^*, c^*) \) with the theoretical proofs pending.

**Example 2** For given parameters in (3.19), we have

\[
g^* = 9506.25, \quad c^* = 39,000, \quad \text{and} \quad T^* \approx 14.36.
\]

By taking \( c = 10,000 \in (g^*, c^*) \) and \( T = T^* \), panel (A) of Fig. 2 shows that no matter how small the initial population size is, solutions of model (1.4)–(1.5) are attracted by the unique \( T \)-periodic solution.

The situation for the case when \( c \in (g^*, c^*) \) and \( T < T^* \), however, is quite tricky. We can only prove the asymptotical stability of \( w_0 \) theoretically, but fail to count the exact number of \( T \)-periodic solutions of model (1.4)–(1.5). To numerically explore this problem, let \( c = 10,000 \in (g^*, c^*) \) and \( T = 14.10 < T^* \). Then, \( w_0 \) is asymptotically stable from Theorem 3.3(2). Moreover, there exists a globally asymptotically stable \( T \)-periodic solution as shown in panel (B) of Fig. 2. Thus, we deduce that model (1.4)–(1.5) has exactly two \( T \)-periodic solutions, the larger one being asymptotically stable, and the smaller one unstable, which has not been proved theoretically at the present time.

From Theorem 3.3, it is easy to see that the following corollary is true.

**Corollary 3.4** Assume that \( g^* < c < c^* \) and \( T \leq T^* \). Then, model (1.4)–(1.5) has a unique \( T \)-periodic solution, which is globally asymptotically stable, if and only if \( T = T^* \).

### 3.2 Release less often with \( T > T^* \)

In this subsection, we consider the case of \( T > T^* \), which means that we release sterile mosquitoes less often. For this case, we have the following theorem.

**Theorem 3.5** Assume that \( c > g^* \) and \( T > T^* \). Then, model (1.4)–(1.5) has a unique \( T \)-periodic solution, which is globally asymptotically stable.

**Proof** From (2.9), we reach \( h'(0) > 1 \), which indicates that \( h(u) > u \) for \( u \in (0, \delta) \), where \( \delta \) is sufficiently small. This, together with (2.6), means that there exists \( u_1 \in [\delta, A) \) such that

\[
h(u_1) = u_1, \quad h'(u_1) \leq 1, \quad \text{and} \quad h(u) > u, \quad \text{for} \quad u \in (0, u_1).
\]

Assume by contradiction that model (1.4)–(1.5) has another \( T \)-periodic solution. Then, there is \( u_2 \in (u_1, A) \) such that

\[
h(u_2) = u_2, \quad h'(u_2) \leq 1, \quad \text{and} \quad h(u) < u, \quad \text{for} \quad u \in (u_2, A).
\]

Hence, we have

\[
h(u_i) = u_i, \quad \text{and} \quad h'(u_i) \leq 1, \quad i = 1, 2, \quad (3.23)
\]

which consists of the following four cases:

\[
h'(u_1) = 1, \quad \text{and} \quad h'(u_2) = 1,
\]

\[
h'(u_1) < 1, \quad \text{and} \quad h'(u_2) = 1,
\]

\[
h'(u_1) < 1, \quad \text{and} \quad h'(u_2) < 1,
\]

\[
\epsilon \quad \text{Springer}
\]
and
\[ h'(u_1) = 1, \quad \text{and} \quad h'(u_2) < 1. \]

From (3.13) and (3.23), the above four cases are equivalent to

\[ Q(u_1) = 0, \quad \text{and} \quad Q(u_2) = 0, \tag{3.24} \]
\[ Q(u_1) < 0, \quad \text{and} \quad Q(u_2) = 0, \tag{3.25} \]
\[ Q(u_1) < 0, \quad \text{and} \quad Q(u_2) < 0, \tag{3.26} \]

and

\[ Q(u_1) = 0, \quad \text{and} \quad Q(u_2) < 0, \tag{3.27} \]

respectively, where \( B, C, D \) are defined in (3.14), and \( Q(u) \) is defined in (3.15).

Since \( Q(A) < 0 \) and \( B = \frac{a - m\mu}{a\xi} > 0 \), we can easily see that (3.24) and (3.25) are impossible.

Now, we show that (3.26) is impossible. In fact, if (3.26) holds, then by (3.13) and (3.23), there is \( \tilde{u} \in (u_1, u_2) \) such that

\[ h(\tilde{u}) = \tilde{u}, \quad \text{and} \quad h'(\tilde{u}) \geq 1, \]

which leads to \( Q(\tilde{u}) \geq 0 \). However, from \( B > 0 \) and \( \tilde{u} \in (u_1, u_2) \), along with (3.26), we must have \( Q(\tilde{u}) < 0 \), a contradiction. Thus, (3.26) is impossible as well.

Finally, we verify that (3.27) is also impossible. To this end, let \( k - 1 > 0 \) be small enough such that

\[ h(u) - ku = 0 \]
has three roots, denoted by \( v_i(k) = v_i, i = 1, 2, 3, \) with

\[ 0 < v_1 < u_1 < v_2 < v_3 < u_2 < A, \]

and

\[ h(v_1) = kv_1, \quad h'(v_1) \leq k, \]
\[ h(v_2) = kv_2, \quad h'(v_2) \geq k, \tag{3.28} \]
\[ h(v_3) = kv_3, \quad h'(v_3) \leq k. \]

Substituting (3.28) in (3.13), we obtain

\[ h'(v_1) = k \left[ \frac{A}{v_1} \left( A - (1 + m)k v_1 \right)^2 + b^2 \left( A - (1 - m)k v_1 \right)^2 \right] \left( v_1 + c \right) \frac{A \left( (v_1 - \frac{c}{k})^2 + b^2 \right) \left[ cA + (mA - (1 - m)c)kv_1 \right]}{A \left( (v_2 - \frac{c}{k})^2 + b^2 \right) \left[ cA + (mA - (1 - m)c)kv_2 \right]} \leq k, \]
\[ h'(v_2) = k \left[ \frac{A}{v_2} \left( A - (1 + m)k v_2 \right)^2 + b^2 \left( A - (1 - m)k v_2 \right)^2 \right] \left( v_2 + c \right) \frac{A \left( (v_2 - \frac{c}{k})^2 + b^2 \right) \left[ cA + (mA - (1 - m)c)kv_2 \right]}{A \left( (v_3 - \frac{c}{k})^2 + b^2 \right) \left[ cA + (mA - (1 - m)c)kv_3 \right]} \geq k, \]
\[ h'(v_3) = k \left[ \frac{A}{v_3} \left( A - (1 + m)k v_3 \right)^2 + b^2 \left( A - (1 - m)k v_3 \right)^2 \right] \left( v_3 + c \right) \frac{A \left( (v_3 - \frac{c}{k})^2 + b^2 \right) \left[ cA + (mA - (1 - m)c)kv_3 \right]}{A \left( (v_1 - \frac{c}{k})^2 + b^2 \right) \left[ cA + (mA - (1 - m)c)kv_1 \right]} \leq k, \]

which are equivalent to

\[ B(k)v_1^2 + C(k)v_1 + D(k) \leq 0, \]
\[ B(k)v_2^2 + C(k)v_2 + D(k) \geq 0, \tag{3.29} \]
\[ B(k)v_3^2 + C(k)v_3 + D(k) \leq 0, \]
respective, where

\[
B(k) = k\left(\frac{(1-m)^2}{\alpha}c + (k-1) mA^2 + (1-m) cA\right),
\]

\[
C(k) = \frac{k^2(1-m)^2}{\alpha}c^2 + (k+1)(mk-1)cA^2 + \frac{2k(m-1)}{\alpha}cA,
\]

\[
D(k) = -\frac{k(1-m)}{\alpha}cA \left( c - \frac{1}{k-1} mk c^* \right).
\]

Let

\[
Q_k(u) = B(k)u^2 + C(k)u + D(k).
\]

Then, (3.29) becomes

\[
Q_k(v_1) \leq 0, \quad Q_k(v_2) \geq 0, \quad \text{and} \quad Q_k(v_3) \leq 0,
\]

which leads to a contradiction, since \( B(k) > 0 \) and \( Q_k(u) \) is a quadratic function. Hence, (3.27) is also impossible. This shows that \( T \)-periodic solution of model (1.4)-(1.5) is unique.

By a similar argument used in the proof of Theorem 3.3(1), we can prove the global asymptotical stability of the unique \( T \)-periodic solution. The proof is complete.

Combining Theorems 3.2 with 3.5, we obtain the following corollary.

**Corollary 3.6** Assume that \( c \geq c^* \). Then, the origin is globally asymptotically stable if and only if \( T \leq T^* \).

### 4 Concluding remarks

Combining the modeling ideas for the interactive wild and sterile mosquitoes in [17], in which only the sexually active sterile mosquitoes are considered, in [29], in which the density dependent survival probability is assumed, and in [19,25,26], in which the releases of the sterile mosquitoes are impulsive, constant and periodic, we formulate and investigate model (1.4)-(1.5) in this paper. In [29], the author supposed that the release function \( g \) of sterile mosquitoes is an independent variable satisfying an independent dynamical equation, see also [1,32]. In [30], the authors treated the release function \( g \) as a given nonnegative continuous function in advance, especially, a constant function related to the release strategy of \( T = \bar{T} \).

Although model (1.4)-(1.5) looks simple, it has rich and complex dynamics including the local and global stability of the origin, the existence, stability and semistability of a unique \( T \)-periodic solution, and the existence and stability of exact two \( T \)-periodic solutions. We have found the corresponding threshold values such as \( T^* \) for the waiting period between two consecutive releases, \( g^* \) and \( c^* \) for the release amount of the sterile mosquitoes each time. We have shown that the origin is asymptotically stable provided \( c \geq c^* \) and \( T \leq T^* \), or \( c \in (g^*, c^*) \) and \( T < T^* \) in Theorem 3.2 and Theorem 3.3(2), respectively, and model (1.4)-(1.5) admits a unique globally asymptotically stable \( T \)-periodic solution, provided \( c \in (g^*, c^*) \) and \( T = T^* \) or \( c > g^* \) and \( T > T^* \) in Theorem 3.3(1) and Theorem 3.5, respectively. Figure 1 verifies all conditions in Theorem 3.2 by four cases: (i) \( c > c^* \) and \( T < T^* \), (ii) \( c = c^* \) and \( T < T^* \), (iii) \( c > c^* \) and \( T = T^* \), and (iv) \( c = c^* \) and \( T = T^* \). Figure 2A, B verifies Theorem 3.3(1) and Theorem 3.3(2), respectively. We should mention here that for the case \( c \in (g^*, c^*) \) and \( T < T^* \), it is possible for model (1.4)-(1.5) to have exact two \( T \)-periodic solutions, or a unique semi-stable \( T \)-periodic solution, or the origin is GAS. We leave this situation as our future work. Furthermore, it remains unknown for the case of \( c \in (0, g^*) \), which will be what we are going to study in the future, and by numerical simulations, we see that model (1.4)-(1.5) may have two \( T \)-periodic solutions, with the smaller one unstable and the bigger one stable.
