Log Crepant Birational Maps and Derived Categories

Yujiro Kawamata

September 10, 2018

1 Introduction

The purpose of this paper is to extend the conjecture stated in the paper [5] to the logarithmic case and prove some supporting evidences. [5] Conjecture 1.2 predicts that birationally equivalent smooth projective varieties have equivalent derived categories if and only if they have equivalent canonical divisors.

According to the experience of the minimal model theory, one has to deal with singular varieties instead of only smooth varieties for the classification of algebraic varieties. Moreover, we should consider not only varieties but also pairs consisting of varieties and divisors on them. These pairs are expected to have some milder singularities, the log terminal singularities.

On the other hand, the theory of derived categories works well under the smoothness assumption of the variety. The reason is that the global dimension is finite only in the case of smooth varieties.

In this paper we shall consider pairs of varieties and \( \mathbb{Q} \)-divisors which have smooth local coverings (Definition 2.1), and conjecture that, if there is an equivalence of log canonical divisors between birationally equivalent pairs, then there is an equivalence of derived categories (Conjecture 2.2). We note that we need to consider the sheaves on the stacks associated to the pairs instead of the usual sheaves on the varieties in order to have equivalences of derived categories as already notices in [4]. This is a generalization of the conjecture in [5], and includes the case considered in [2]. We note that crepant resolutions in higher dimensions are rare but there are many log crepant partial resolutions of quotient singularities by finite subgroups of
general linear groups. We note also that, even in the case in which there is a birational morphism between varieties, the direction of the inclusion of the category may be different from that of the morphism, but coincides with that of the inequality of the log canonical divisors.

In §3, we consider the problem on recovering the variety from the category. We prove that some basic birational invariants related to the canonical divisors can be recovered from the derived category (Theorem 3.1). In particular, we prove the converse statement of the conjecture. On the other hand, we remark that the variety itself can be reconstructed from the category of coherent sheaves (Theorem 3.2).

In §4, we consider the toroidal varieties and prove that the conjecture holds in this case (Theorem 4.2). This is a generalization of §1 Theorem 5.2. We note that our result implies the McKay correspondence for abelian quotient singularities as a special case.

We conclude the paper with a remark on the relationship with the non-commutative geometry in Proposition 4.7. We maybe need the moduli theoretic interpretation of the log crepant maps in order to deal with the conjecture in the difficult general case.

The author would like to thank Yong-bin Ruan, Tom Bridgeland, Andrei Caldararu and Kenji Matsuki for useful discussions.

2 Derived equivalence conjecture

We shall consider pairs of varieties with $\mathbb{Q}$-divisors which have local coverings by smooth varieties:

**Definition 2.1.** Let $X$ be a normal variety, and $B$ an effective $\mathbb{Q}$-divisor on $X$ whose coefficients belong to the standard set $\{1 - 1/n; n \in \mathbb{N}\}$. Assume the following condition.

(*) There exists a quasi-finite and surjective morphism $\pi : U \to X$ from a smooth variety, which may be reducible, such that $\pi^*(K_X + B) = K_U$.

Let $R = (U \times_X U)$ be the normalization of the fiber product. Then the projections $p_i : R \to U$ are etale for $i = 1, 2$, because there is no ramification divisor for $p_i$.

We define the associated Deligne-Mumford stack $\mathcal{X}$ as a 2-functor

$$\mathcal{X} : (Sch) \to (Groupoid)$$
where \((\text{Sch})\) is the category of schemes and \((\text{Groupoid})\) is the 2-category of groupoids, categories themselves whose morphisms are only isomorphisms. The 2-functor \(\mathcal{X}\) is the sheaf with respect to the etale topology which is defined in the following way. For any scheme \(B\), an object of the category \(\mathcal{X}(B)\) is an element of the set \(U(B) = \text{Hom}(B, U)\), and a morphism of the category \(\mathcal{X}(B)\) is an element of the set \(R(B) = \text{Hom}(B, R)\). For a morphism \(f : B' \to B\), we have a functor \(f^* : \mathcal{X}(B) \to \mathcal{X}(B')\) given by \(f^* : U(B) \to U(B')\) and \(f^* : R(B) \to R(B')\).

If we replace \(U\) by its etale covering, then the category \(\mathcal{X}(B)\) is replaced by an equivalent category so that the stack \(\mathcal{X}\) does not depend on the choice of the covering \(\pi : U \to X\) but only on the pair \((X, B)\).

**Conjecture 2.2.** Let \((X, B)\) and \((Y, C)\) be pairs of quasi-projective varieties with \(\mathbb{Q}\)-divisors which satisfy the condition (*) in Definition 2.1, and let \(\mathcal{X}\) and \(\mathcal{Y}\) be the associated stacks. Assume that there are proper birational morphisms \(\mu : W \to X\) and \(\nu : W \to Y\) from a third variety \(W\) such that \(\mu^*(K_X + B) = \nu^*(K_Y + C)\). Then there exists an equivalence as triangulated categories \(D^b(\text{Coh}(\mathcal{X})) \to D^b(\text{Coh}(\mathcal{Y}))\).

The pairs considered in the conjecture are very special kind of log terminal pairs. But our assumption is sufficiently general in dimension 2:

**Proposition 2.3.** (1) Let \((X, B)\) be a pair which satisfies the condition (*) in Definition 2.1. Then the pair \((X, B)\) is log terminal.

(2) Let \(X\) be a normal surface, and \(B\) an effective \(\mathbb{Q}\)-divisor on \(X\) whose coefficients belong to the standard set \(\{1 - 1/n; n \in \mathbb{N}\}\). Assume that the pair \((X, B)\) is log terminal. Then the pair satisfies the condition (*) in Definition 2.1.

**Proof.** (1) Let \(\mu : Y \to X\) be a proper birational morphism, and \(E\) an exceptional prime divisor of \(\mu\). Then there is a birational morphism \(\nu : V \to U\) with a quasi-finite morphism \(\rho : V \to Y\) and a exceptional prime divisor \(F\) of \(\rho\) which dominates \(E\). We can write \(\mu^*(K_X + B) = K_Y + aE + \ldots\) and \(\nu^*K_U = K_V + bF + \ldots\). If \(e\) is the ramification index of the morphism \(\rho\) along \(F\), then we have \(b = ae + (e - 1)\). Since \(b > 0\), we conclude that \(a > -1\).

(2) We may always replace \(X\) by its open covering in the etale topology in the course of the proof. Fixing a point \(x \in X\), we shall construct our covering in a neighborhood of \(x\). Let \(\{n_1, n_2, \ldots\}\) be the set of all integers such that
the numbers $1 - 1/n_i$ appear as coefficients of irreducible components of $B$ which pass through $x$. We may assume that $n_1 > n_2 > \ldots$.

By the classification of log terminal singularities on surfaces, $X$ has only quotient singularities in the etale topology. Thus there is a quasi-finite and surjective morphism $\pi_1 : X_1 \to X$ from a smooth surface which is etale in codimension 1. Let $B_1 = \pi_1^*B$. By shrinking $X_1$ if necessary, we can take a cyclic Galois covering $\pi_2 : X_2 \to X_1$ of order $n_1$ which ramifies along the irreducible components of $B_1$ whose coefficients are equal to $1 - 1/n_1$. Let $B_1'$ be the sum of all the other irreducible components. Then we can show that the pair $(X_2, B_2)$ with $B_2 = \pi_2^*B_1'$ is again log terminal by a similar argument as in (1).

Since the set of integers arising from the coefficients of new pair $(X_2, B_2)$ is smaller, we obtain our assertion by induction.

Example 2.4. (1) Let $X = \mathbb{C}^2/\mathbb{Z}_8(1, 3)$, and $f : Y \to X$ the minimal resolution. Then $f^*K_X = K_Y + \frac{1}{2}(C_1 + C_2)$ for the exceptional divisors $C_1$ and $C_2$; $f$ is log crepant as a morphism from $(Y, \frac{1}{2}(C_1 + C_2))$ to $(X, 0)$. Furthermore, let $g : Z \to Y$ be the blowing up at the point $y_0 = C_1 \cap C_2$. Then $g^*(K_Y + \frac{1}{2}(C_1 + C_2)) = K_Z + \frac{1}{2}(C_1' + C_2')$, where $C_i'$ is the strict transform of $C_i$ for $i = 1, 2$. Thus $f \circ g$ is log crepant as a morphism from $(Z, \frac{1}{2}(C_1' + C_2'))$ to $(X, 0)$.

(2) Let $X = \mathbb{C}^2$, $D_i$ ($i = 1, 2$) the coordinate curves, and $f : Y \to X$ the weighted blowing up at the origin $x_0 = D_1 \cap D_2$ with weight (1, 2). Then $Y$ has one ordinary double point, and $f^*(K_X + \frac{2}{3}(D_1 + D_2)) = K_Y + \frac{2}{3}(D_1' + D_2')$, where $D_i'$ is the strict transform of $D_i$ for $i = 1, 2$. Thus $f$ is log crepant as a morphism from $(Y, \frac{2}{3}(D_1' + D_2'))$ to $(X, \frac{2}{3}(D_1 + D_2))$.

3 Recovery of varieties from categories

The variety cannot be recovered from the derived category, but the canonical divisor can because the Serre functor is categorical:

Theorem 3.1. Let $(X, B)$ and $(Y, C)$ be pairs of projective varieties with $\mathbb{Q}$-divisors which satisfy the condition (*) in Definition 2.1, and let $\mathcal{X}$ and $\mathcal{Y}$ be the associated stacks. Assume that there is an equivalence as triangulated categories:

$$F : D^b(\text{Coh}(\mathcal{X})) \to D^b(\text{Coh}(\mathcal{Y})).$$

Then the following hold:
(1) \( \dim X = \dim Y \).

(2) \( K_X + B \) (resp. \( -(K_X + B) \)) is nef if and only if \( K_Y + C \) (resp. \( -(K_Y + C) \)) is nef. Moreover, if this is the case, then the numerical Kodaira dimensions are equal

\[
\nu(X, \pm(K_X + B)) = \nu(Y, \pm(K_Y + C)).
\]

(3) If \( K_X + B \) or \( -(K_X + B) \) is big, then there are birational morphisms \( \mu : W \to X \) and \( \nu : W \to Y \) from a third projective variety \( W \) such that \( \mu^*(K_X + B) = \nu^*(K_Y + C) \).

(4) There is an isomorphism of big canonical rings as graded \( \mathbb{C} \)-algebras

\[
\bigoplus_{m \in \mathbb{Z}} H^0(X, \cup m(K_X + B) \cup) \to \bigoplus_{m \in \mathbb{Z}} H^0(Y, \cup m(K_Y + C) \cup).
\]

Proof. By \([6]\), there exists an object on the product stack \( e \in D^b(\text{Coh}(X \times Y)) \) which is the kernel of the equivalence: \( F \) is isomorphic to the integral functor \( \Phi \) defined by \( \Phi(a) = p_2^*(p_1^*a \otimes e) \). Then the proofs of the statements (1) through (3) are similar to those in \([5]\).

(4) This is due to Bridgeland and Caldararu. Let \( e' \in D^b(\text{Coh}(X \times Y)) \) be the kernel of the quasi-inverse of \( F \). Let \( \Delta_X : X \to X \times X \) and \( \Delta_Y : Y \to Y \times Y \) be diagonal morphisms. Then \( e \boxtimes e' \in D^b(\text{Coh}(X \times Y \times X \times Y)) \) is the kernel of an equivalence

\[
G : D^b(\text{Coh}(X \times X)) \to D^b(\text{Coh}(Y \times Y))
\]

which satisfies

\[
G(\Delta_X \omega_X^m) \cong \Delta_Y \omega_Y^m
\]

for any integer \( m \) by \([5]\). The conclusion follows from the following isomorphisms for \( m, m' \in \mathbb{Z} \)

\[
\begin{align*}
\text{Hom}_{X \times X}(\Delta_X \omega_X^m, \Delta_X \omega_X^{m'}) & \cong \text{Hom}_X(\Delta_X \Delta_X \omega_X^m, \omega_X^{m'}) \\
& \cong \text{Hom}_X(\omega_X^m \otimes \bigoplus_{p=0}^{\dim X} \Omega_X[p], \omega_X^{m'}) \cong \text{Hom}_X(\omega_X^m, \omega_X^{m'}). 
\end{align*}
\]

The variety can be recovered from the category of sheaves.
Theorem 3.2. Let \((X, B)\) and \((Y, C)\) be pairs of projective varieties with \(\mathbb{Q}\)-divisors which satisfy the condition (*) in Definition 2.1, and let \(\mathcal{X}\) and \(\mathcal{Y}\) be the associated stacks. Assume that there is an equivalence as abelian categories:

\[
F : \text{Coh}(\mathcal{X}) \to \text{Coh}(\mathcal{Y}).
\]

Then there exists an isomorphism \(f : X \to Y\) such that \(f_*B = C\). Moreover, if \(X\) is smooth and \(B = 0\), then there exists an invertible sheaf \(L\) on \(Y\) such that \(F\) is isomorphic to the functor \(f_*L\) defined by \(f_*L(a) = f_*a \otimes L\).

Proof. The functor \(F\) is extendable to an equivalence as triangulated categories

\[
\tilde{F} : D^b(\text{Coh}(\mathcal{X})) \to D^b(\text{Coh}(\mathcal{Y})).
\]

By [6], there exists an object on the product stack \(e \in D^b(\text{Coh}(\mathcal{X} \times \mathcal{Y}))\) such that \(\tilde{F}\) is isomorphic to the integral functor \(\Phi^e_{\mathcal{X} \to \mathcal{Y}}\). The object \(\mathcal{O}_x \in \text{Coh}(\mathcal{X})\) for \(x \in X\) is simple, i.e., is non-zero and has no non-trivial subobject. Then the image \(p_{2*}(p_1^*\mathcal{O}_x \otimes e)\) is also simple and supported at a point. Therefore, the support of \(e\) is a graph of a bijection \(f : X \to Y\), which is an isomorphism by the Zariski main theorem. The coefficient of \(B\) at any irreducible component is determined by the number of non-isomorphic simple objects above its generic point. It follows that \(C = f_*B\).

Under the additional assumption, we have

\[
p_{2*}(p_1^*\mathcal{O}_x \otimes e) \cong \mathcal{O}_{f(x)}
\]

for any point \(x \in X\). Therefore, \(e\) is an invertible sheaf on the graph of \(f\).

\(\square\)

4 Toroidal case

We confirm our conjecture in the case of toroidal varieties.

Definition 4.1. Let \(X\) be a normal variety and \(\bar{B}\) a reduced divisor. The pair \((X, \bar{B})\) is said to be toroidal if, for each \(x \in X\), there exists a toric variety \((P_x, Q_x)\) with a point \(t\), called a toric chart, such that the completion \((\hat{X}_x, \hat{B}_x)\) at \(x\) is isomorphic to the completion \((\hat{P}_x)_t, (\hat{Q}_x)_t\) at \(t\). A toroidal pair is said to be quasi-smooth if it has only quotient singularities. Such a pair always satisfies the condition (*) in Definition 2.1.

6
A morphism \( f : (X, \bar{B}) \to (Y, \bar{C}) \) of toroidal pairs is said to be toroidal if, for any point \( x \in X \) and any toric chart \( (P_y', Q_y'; t') \) at \( y = f(x) \in Y \), there exists a toric chart \( (P_x, Q_x; t) \) at \( x \) and a toric morphism \( g_x : (P_x, Q_x) \to (P_y, Q_y) \) such that \( g_x(t) = t' \) and the completion \( \hat{f}_x : (\hat{X}_x, \hat{\bar{B}}_x) \to (\hat{Y}_y, \hat{\bar{C}}_y) \) is isomorphic to the completion \( \hat{g}_x t : (\hat{P}_x t, (\hat{Q}_x)_t) \to ((\hat{P}_y') t', (\hat{Q}_y') t') \) under the toric chart isomorphisms.

A toroidal morphism \( f : (X, B) \to (Y, C) \) is said to be a divisorial contraction if it is a projective birational morphism and such that the exceptional locus is a prime divisor. A pair of toroidal morphisms \( \phi : (X, B) \to (Z, D) \) and \( \psi : (Y, C) \to (Z, D) \) is said to be a flip if they are projective birational morphisms such that the codimensions of their exceptional loci are at least 2, the composite map \( (\psi)^{-1} \circ \phi \) is not an isomorphism, and that the relative Picard numbers \( \rho(X/Z) \) and \( \rho(Y/Z) \) are equal to 1.

**Theorem 4.2.** Let \( X \) and \( Y \) be quasi-smooth toroidal varieties, \( B \) and \( C \) be effective toroidal \( \mathbb{Q} \)-divisors on \( X \) and \( Y \), respectively, whose coefficients are contained in the set \( \{1 - 1/r | r \in \mathbb{Z}_{>0}\} \), and let \( X \) and \( Y \) be smooth Deligne-Mumford stacks associated to the pairs \( (X, B) \) and \( (Y, C) \), respectively. Assume that one of the following holds.

1. \( X = Y \) and \( K_X + B \geq K_Y + C \).
2. There is a toroidal divisorial contraction \( f : X \to Y \) such that \( C = f_* B \) and \( K_X + B \geq f^*(K_Y + C) \).
3. There is a toroidal flip \( f : X \to Z \leftarrow Y \) such that \( C = f_* B \) and \( \mu^*(K_X + B) \geq \nu^*(K_Y + C) \)
4. There is a toroidal divisorial contraction \( f : Y \to X \) such that \( B = f_* C \) and \( f^*(K_X + B) \geq K_Y + C \).

Setting \( Z = Y \) in the cases (1) and (2) and \( Z = X \) in the case (4), let \( W = (X \times_Z Y) \) be the normalization of the fiber product with the natural morphisms \( \bar{\mu} : W \to X \) and \( \bar{\nu} : W \to Y \). Then the functor

\[
F = \bar{\mu}_* \bar{\nu}^* : D^b(Coh(Y)) \to D^b(Coh(X)).
\]

is fully faithful. Moreover, if the inequality between the log canonical divisors become an equality, then \( F \) is an equivalence of triangulated categories.
Proof. Since the set of all the point sheaves span the derived categories, our assertion can be proved analytic locally. Hence we may assume that $X, Y, Z$ are toric varieties, $Z$ is affine, and that $f$ is a toric map. We note that the toroidal structure is only necessary near the exceptional locus of the given birational maps for the application of the theorem.

It is sufficient to prove the first assertion. Indeed, if the pull backs of $K_X + B$ and $K_Y + C$ are equal, then $F$ is automatically an equivalence, because it commutes with the Serre functors (II).

Let $N$ be a lattice in $\mathbb{R}^n$ which contains $\mathbb{Z}^n$, $M$ its dual lattice. Assume that the standard vectors $v_1 = (1, 0, \ldots, 0), \ldots, v_n = (0, \ldots, 0, 1)$ are primitive in $N$. Let $\{v_i^*\}_{1 \leq i \leq n}$ be the dual basis of $\{v_i\}_{1 \leq i \leq n}$.

(1) Let $X = Y = Z$ be the affine toric variety corresponding to the cone $\sigma \subset N_\mathbb{R}$ generated by $v_1, \ldots, v_n$. Let $D_i$ be the prime divisors on $X$ corresponding to the $v_i$. Let $r_i$ and $s_i$ be positive integers attached to the divisors $D_i$ for $1 \leq i \leq n$ such that we have $B = \sum_i (1 - \frac{1}{r_i})D_i$ and $C = \sum_i (1 - \frac{1}{s_i})D_i$. By assumption, we have $r_i \geq s_i$ for all $i$.

The stacks $\mathcal{X}$ and $\mathcal{Y}$ are defined by the coverings $\pi_X : \tilde{X} \to X$ and $\pi_Y : \tilde{Y} \to Y$ which correspond to the sublattices $N_X$ and $N_Y$ of $N$ generated by the $r_i v_i$ and $s_i v_i$ for $1 \leq i \leq n$, respectively. The stack $\mathcal{W}$ is defined by the covering $\pi_W : \tilde{W} \to X$ which correspond to the sublattice $N_W = N_X \cap N_Y \subset N$. Let $M_X$, $M_Y$ and $M_W$ be the dual lattices of $N_X$, $N_Y$ and $N_W$, respectively. The morphisms $\tilde{\mu} : \mathcal{W} \to \mathcal{X}$ and $\tilde{\nu} : \mathcal{W} \to \mathcal{Y}$ are given by inclusions $M_X \subset M_W$ and $M_Y \subset M_W$, respectively. $M_X$ and $M_Y$ are generated by the $\frac{1}{r_i} v_i^*$ and $\frac{1}{s_i} v_i^*$, respectively. The dual lattice $M_W$ is equal to the sum $M_X + M_Y \subset M_\mathbb{Q}$ generated by the $\frac{1}{t_i} v_i^*$ with $t_i = \text{LCM}(r_i, s_i)$.

Let $m = \sum_{i=1}^{n} \frac{m_i}{s_i} v_i^* \in M_Y$ for $m_i \in \mathbb{Z}$ be a monomial which generates an invertible sheaf $L = \mathcal{O}_\mathcal{Y}(\sum_{i=1}^{n} \frac{m_i}{s_i} D_i)$ on $\mathcal{Y}$. Then the invertible sheaf $\tilde{\nu}^* L$ on $\mathcal{W}$ is generated by the same monomial $m$, hence $F(L)$ on $\mathcal{X}$ is by the generator

$$F(m) = \sum_{i=1}^{n} \frac{r_i}{s_i} v_i^*$$

of $(m + \tilde{\sigma}) \cap M_X$. Let $L'$ be another invertible sheaf with the corresponding monomials

$$m' = \sum_{i=1}^{n} \frac{m_i'}{s_i} v_i^*, \quad F(m') = \sum_{i=1}^{n} \frac{r_i}{s_i} v_i^*.$$
We have
\[ \text{Hom}(L', L) = \mathbb{C}^{(m-m'+\sigma)\cap M} \]
\[ \text{Hom}(F(L'), F(L)) = \mathbb{C}^{(F(m)-F(m')-\sigma)\cap M}. \]

We calculate
\[ 0 \leq \left\lfloor \frac{m_i - m'_i}{s_i} \right\rfloor r_i + \left\lfloor \frac{m'_i r_i}{s_i} - \frac{m_i r_i}{s_i} \right\rfloor \leq (1 - \frac{1}{s_i}) r_i + (1 - \frac{1}{s_i}) < r_i \]
because \( s_i \leq r_i \). Thus
\[ 0 \leq \left\lfloor \frac{m_i - m'_i}{s_i} \right\rfloor r_i + \left\lfloor \frac{m'_i r_i}{s_i} - \frac{m_i r_i}{s_i} \right\rfloor < r_i \]
hence
\[ \left\lfloor \frac{m_i - m'_i}{s_i} \right\rfloor = \left\lfloor \frac{m'_i r_i}{s_i} - \frac{m_i r_i}{s_i} \right\rfloor \frac{r_i}{r_i}. \]

Therefore, the homomorphism
\[ \text{Hom}(L', L) \to \text{Hom}(F(L'), F(L)) \]
is bijective.

(2) Let \( Y = Z \) be the affine toric variety corresponding to the cone \( \sigma \subset \mathbb{N}_R \) generated by \( v_1, \ldots, v_n \) as in (1). Let \( v_{n+1} = (a_1, \ldots, a_n) \in N \) be a primitive vector such that \( a_i > 0 \) for \( 1 \leq i \leq n' \) and \( a_i = 0 \) for \( n' < i \leq n \). We assume that \( n' \geq 2 \). If we put \( a_{n+1} = -1 \), then we have
\[ \sum_{i=1}^{n+1} a_i v_i = 0. \]

Let \( \sigma_{i_0} \) \((1 \leq i_0 \leq n')\) be the subcones of \( \sigma \) generated by the \( v_i \) for \( 1 \leq i \leq n \) with \( i \neq i_0 \). Then there is a decomposition \( \sigma = \bigcup_{i=1}^{n'} \sigma_i \). Let \( f : X \to Y \) be the corresponding projective birational toric morphism, let \( D_i \) be the prime divisors on \( X \) corresponding to the \( v_i \) for \( 1 \leq i \leq n + 1 \), and \( D'_i \) their strict transforms on \( Y \). \( D_{n+1} \) is the exceptional divisor of \( f \), and we put \( D'_{n+1} = 0 \). Then we have \( f^* D'_i = D_i + a_i D_{n+1} \), hence \( D_i \equiv -a_i D_{n+1} \). The divisors \( D_i \) for \( 1 \leq i \leq n' \) are positive for \( f \).
Let $r_i$ be positive integers attached to the divisors $D_i$ for $1 \leq i \leq n + 1$ such that we have $B = \sum_i (1 - \frac{1}{r_i})D_i$. Our condition

$$K_X + \sum_{i=1}^{n+1} \frac{r_i - 1}{r_i} D_i \geq f^*(K_Y + \sum_{i=1}^{n} \frac{r_i - 1}{r_i} D'_i).$$

is equivalent to

$$\sum_{i=1}^{n+1} \frac{a_i}{r_i} \geq 0$$

because $K_X + \sum_{i=1}^{n+1} D_i = f^*(K_Y + \sum_{i=1}^{n} D'_i)$.

The toric variety $X$ is covered by the affine toric varieties $X_{\sigma_{i_0}}$ for $1 \leq i_0 \leq n$. The stacks $\mathcal{X}$ and $\mathcal{Y}$ are defined by the coverings $\pi_{X,i_0} : \tilde{X}_{\sigma_{i_0}} \to X_{\sigma_{i_0}}$ and $\pi_Y : \tilde{Y} \to Y$ which correspond to the sublattices $N_{i_0}$ of $N$ generated by the $r_i v_i$ for $1 \leq i \leq n + 1$ with $i \neq i_0$ and $N_{n+1}$ generated by the $r_i v_i$ for $1 \leq i \leq n$, respectively. The stack $\mathcal{W}$ above $X$ is defined by the coverings $\pi_{W,i_0} : \tilde{W}_{\sigma_{i_0}} \to X_{\sigma_{i_0}}$ which correspond to the sublattices $N_{i_0,n+1} = N_{i_0} \cap N_{n+1} \subset N$. We note that the morphism of stacks $\tilde{\mu} : \mathcal{W} \to \mathcal{X}$ is not necessarily an isomorphism. If $1 \leq i_0 \leq n$, then the dual lattice $M_{i_0}$ of $N_{i_0}$ is generated by $\frac{1}{r_i} v_i^* - \frac{a_i}{a_{i_0} r_i} v_{i_0}^*$ for $1 \leq i \leq n$ with $i \neq i_0$ and $\frac{1}{a_{i_0} r_{n+1}} v_{i_0}^*$. The dual lattice $M_{i_0,n+1}$ of $N_{i_0,n+1}$ is generated by $\frac{1}{r_i} v_i^*$ for $1 \leq i \leq n$. The dual lattice $M_{i_0,n+1}$ of $N_{i_0,n+1}$ is equal to the sum $\hat{M}_{i_0} + M_{n+1} \subset M_{i_0}$.

Let $m = \sum_{i=1}^{n+1} k_i v_i^* \in M_{n+1}$ with $k_i \in \mathbb{Z}$ be a monomial which corresponds to an invertible sheaf $L$ on $\mathcal{Y}$. Then the invertible sheaf $F(L)$ on $\mathcal{X}$ is given by the generators $m_{i_0}$ of $(m + \sigma_{i_0}) \cap M_{i_0}$ given by

$$m_{i_0} = \sum_{1 \leq i \leq n, i \neq i_0} \frac{k_i v_i^*}{r_i} + \left( \frac{k_{n+1}}{a_{i_0} r_{n+1}} - \sum_{1 \leq i \leq n, i \neq i_0} \frac{a_i k_i}{a_{i_0} r_i} \right) v_{i_0}^*$$

where $k_{n+1}$ is a smallest integer such that

$$\frac{k_{n+1}}{a_{i_0} r_{n+1}} - \sum_{1 \leq i \leq n, i \neq i_0} \frac{a_i k_i}{a_{i_0} r_i} \geq \frac{k_{i_0}}{r_{i_0}},$$

that is

$$k_{n+1} \geq r_{n+1} \sum_{i=1}^{n} \frac{a_i k_i}{r_i}.$$
We note that $k_{n+1}$ is independent of $i_0$. Let $L'$ be another invertible sheaf corresponding to the monomial $m' = \sum_{i=1}^{n} k_i v_i^*$, and let

$$m'_{i_0} = \sum_{1 \leq i \leq n, i \neq i_0} \frac{k_i'}{r_i} v_i^* - \sum_{1 \leq i \leq n+1, i \neq i_0} \frac{a_i k_i'}{a_i r_i v_{i_0}^*}, \quad k'_{n+1} = r r_{n+1} \sum_{i=1}^{n} \frac{a_i k_i'}{r_i}$$

where we note that $a_{n+1} = -1$.

Since $f$ is birational and $\text{Hom}(L', L)$ is torsion free, the natural homomorphism

$$\text{Hom}(L', L) \to \text{Hom}(F(L'), F(L))$$

is injective. It is also surjective because the complement of the indeterminacy locus of $f^{-1}$ in $Y$ has codimension at least 2. Since $\text{Hom}^p(L', L) = 0$ for $p > 0$, it is sufficient to prove that $\text{Hom}^p(F(L'), F(L)) = 0$ for $p > 0$ in order to prove that $F$ is fully faithful.

The invertible sheaf $\text{Hom}(F(L'), F(L))$ is given by the monomials

$$m_{i_0} - m'_{i_0} = \sum_{1 \leq i \leq n, i \neq i_0} \frac{k_i - k_i'}{r_i} v_i^* - \sum_{1 \leq i \leq n+1, i \neq i_0} \frac{a_i (k_i - k_i')}{a_i r_i} v_{i_0}^*.$$

We consider the divisorial reflexive sheaf

$$\text{Hom}(F(L'), F(L))_X = O_X(- \sum_{i=1}^{n+1} \frac{r_i k_i - k_i'}{r_i} D_i)$$

on $X$. Since $f^* D_i' \equiv D_i + a_i D_{n+1}$ for $1 \leq i \leq n$, we have

$$- \sum_{i=1}^{n+1} \frac{r_i k_i - k_i'}{r_i} \gamma D_i \equiv \sum_{i=1}^{n+1} a_i \gamma \frac{r_i k_i - k_i'}{r_i} \gamma D_{n+1}.$$

We calculate

$$\sum_{i=1}^{n+1} \frac{a_i (k_i - k_i')}{r_i}$$

$$= \sum_{i=1}^{n} \frac{a_i (k_i - k_i')}{r_i} - \frac{r r_{n+1} \sum_{i=1}^{n} \frac{a_i k_i}{r_i}}{r_{n+1}} + \frac{r r_{n+1} \sum_{i=1}^{n} \frac{a_i k_i'}{r_i}}{r_{n+1}}$$

$$< \frac{1}{r_{n+1}} \sum_{i=1}^{n} \frac{a_i}{r_i}.$$
Therefore we have
\[
\sum_{i=1}^{n+1} a_i \frac{k_i - k'_i - r_i}{r_i} \leq \sum_{i=1}^{n+1} a_i (k_i - k'_i) + \sum_{i=1}^{n} a_i (r_i - 1) < \sum_{i=1}^{n} a_i.
\]

On the other hand, we have \( K_X + D_{n+1} \equiv \left( \sum_{i=1}^{n} a_i \right) D_{n+1} \). Since \(-D_{n+1}\) is an \( f \)-ample \( \mathbb{Q} \)-divisor, we conclude by the vanishing theorem ([7] Theorem 1.2.5) that
\[
\text{Hom}^p(F(L'), F(L)) \cong H^p(\text{Hom}(F(L'), F(L))_X) = 0
\]
for \( p > 0 \).

(3) Let \( v_{n+1} = (a_1, \ldots, a_n) \in N \) be a primitive vector such that \( a_i > 0 \) for \( 1 \leq i \leq n' \), \( a_i = 0 \) for \( n' < i \leq n'' \) and \( a_i < 0 \) for \( n'' < i \leq n \). We assume that \( 2 \leq n' \) and \( n'' < n \). If we put \( a_{n+1} = -1 \), then we have
\[
\sum_{i=1}^{n+1} a_i v_i = 0.
\]

Let \( \langle v_1, \ldots, v_{n+1} \rangle \) be the convex cone generated by the \( v_i \) for \( 1 \leq i \leq n+1 \), and let \( \sigma_{i_0} \) (\( 1 \leq i_0 \leq n+1 \)) be the subcones generated by the \( v_i \) for \( 1 \leq i \leq n+1 \) with \( i \neq i_0 \). Then there are two decompositions:
\[
\langle v_1, \ldots, v_{n+1} \rangle = \bigcup_{i=1}^{n'} \sigma_i = \bigcup_{i=n'+1}^{n+1} \sigma_i.
\]

Let \( Z \) be an affine toric variety corresponding to the lattice \( N \) and the cone \( \langle v_1, \ldots, v_{n+1} \rangle \). Let \( g : X \to Z \) and \( h : Y \to Z \) be projective birational toric morphisms corresponding to these subdivisions, and let \( f = h \circ g^{-1} : X \to Y \) be the composite proper birational map. Let \( D_i \) be the prime divisors on \( X \) corresponding to the \( v_i \) for \( 1 \leq i \leq n+1 \), and \( D'_i \) their strict transforms on \( Y \). Then we have \( D_i \equiv -a_i D_{n+1} \), \( D'_i \equiv -a_i D'_{n+1} \). The divisors \( D_i \) (\( 1 \leq i \leq n' \)) are positive for \( g \), and the \( D_i \) (\( n'' < i \leq n+1 \)) negative.

Let \( v_{n+2} = \sum_{i=1}^{n'} \lambda a_i v_i = \sum_{i=n'+1}^{n+1} \lambda (-a_i) v_i \), where \( \lambda \) is the smallest positive number such that \( v_{n+2} \) becomes a primitive vector in \( N \). We define the subcones \( \sigma_{i_0 i_1} \) for \( 1 \leq i_0 \leq n' \) and \( n'' < i_1 \leq n+1 \) to be the ones generated
by the $v_i$ for $1 \leq i \leq n + 1$ with $i \neq i_0, i_1$ and $v_{n+2}$. Then we have two decompositions
\[ \sigma_{i_1} = \bigcup_{i=1}^{n'} \sigma_{ii_1}, \quad \sigma_{i_0} = \bigcup_{i=n'+1}^{n+1} \sigma_{i_0i} \]
so that
\[ \langle v_1, \ldots, v_{n+1} \rangle = \bigcup_{1 \leq i \leq n', n'+1 \leq j \leq n+1} \sigma_{ij}. \]

Let $W$ be the toric variety corresponding to this subdivision with natural projective birational morphisms $\mu : W \to X$ and $\nu : W \to Y$:
\[
\begin{array}{ccc}
W & \xrightarrow{\mu} & Y \\
\downarrow \mu & & \downarrow h \\
X & \xrightarrow{g} & Z.
\end{array}
\]

Let $D''_i$ be the prime divisors on $W$ corresponding to the $v_i$ for $1 \leq i \leq n+2$. We have
\[
\begin{align*}
\mu^* D_i &= \begin{cases} 
D''_i & \text{if } 1 \leq i \leq n' \\
D''_i + \lambda(-a_i)D''_{n+2} & \text{if } n'' < i \leq n + 1
\end{cases} \\
\nu^* D'_i &= \begin{cases} 
D''_i + \lambda a_i D''_{n+2} & \text{if } 1 \leq i \leq n' \\
D''_i & \text{if } n'' < i \leq n + 1.
\end{cases}
\]

If $r_1, \ldots, r_{n+1}$ are the positive integers attached to the divisors $D_i$, then our condition
\[
\mu^*(K_X + \sum_{i=1}^{n+1} \frac{r_i - 1}{r_i} D_i) \geq \nu^*(K_Y + \sum_{i=1}^{n+1} \frac{r_i - 1}{r_i} D'_i).
\]
is equivalent to
\[
\sum_{i=1}^{n+1} \frac{a_i}{r_i} \geq 0
\]
because $\mu^*(K_X + \sum_{i=1}^{n+1} D_i) = \nu^*(K_Y + \sum_{i=1}^{n+1} D'_i) = K_W + \sum_{i=1}^{n+2} D''_i$.

The toric varieties $X$ and $Y$ are covered by the affine toric varieties $X_{\sigma_{i_0}}$ for $1 \leq i_0 \leq n'$ and $Y_{\sigma_{i_0}}$ for $n'' < i_0 \leq n + 1$, respectively. The stacks $\mathcal{X}$ and $\mathcal{Y}$
are defined by the coverings \( \pi_{X,i_0} : \tilde{X}_{\sigma_{i_0}} \to X_{\sigma_{i_0}} \) and \( \pi_{Y,i_0} : \tilde{Y}_{\sigma_{i_0}} \to Y_{\sigma_{i_0}} \) which correspond to the sublattices \( N_{i_0} \) of \( N \) generated by the \( r_i v_i \) for \( 1 \leq i \leq n + 1 \) with \( i \neq i_0 \). \( W \) is covered by \( W_{\sigma_{i_0}i} \) for \( 1 \leq i_0 \leq n' \) and \( n'' \leq i_1 \leq n + 1 \), and the stack \( W \) is defined by the coverings \( \pi_{W,i_0i_1} : \tilde{W}_{\sigma_{i_0}i_1} \to W_{\sigma_{i_0}i_1} \) which correspond to the sublattices \( N_{i_0i_1} = N_{i_0} \cap N_{i_1} \subset N \). The morphisms \( \mu : W \to X \) and \( \nu : W \to Y \) are covered by morphisms \( \tilde{\mu} : \tilde{W} \to \tilde{X} \) and \( \tilde{\nu} : \tilde{W} \to \tilde{Y} \) of stacks. If \( 1 \leq i_0 \leq n \), then the dual lattice \( M_{i_0} \) of \( N_{i_0} \) is generated by \( \frac{1}{r_i} v_i^* - \frac{a_i}{a_i r_i} v_{i_0}^* \) for \( 1 \leq i \leq n \) with \( i \neq i_0 \) and \( \frac{1}{a_i r_{i+1}} v_{i+1}^* \). The dual lattice \( M_{n+1} \) of \( N_{n+1} \) is generated by \( \frac{1}{r_i} v_i^* \) for \( 1 \leq i \leq n \). The dual lattice \( M_{n+1} \) of \( N_{n+1} \) is equal to the sum \( M_{i_0} + M_{i_1} \subset M_Q \).

Let \( L = \mathcal{O}_X(\sum_{i=1}^{n+1} k_i D_i') \) be an invertible sheaf on \( X \), where \( k_i \) are integers. We have

\[
\tilde{\nu}^* L = \mathcal{O}_Y(\sum_{i=1}^{n+1} \frac{k_i}{r_i} D_i'' + \sum_{i=1}^{n'} \frac{\lambda a_i k_i}{r_i} D_{n+2}'')
\]

\[
= \tilde{\mu}^* \mathcal{O}_X(\sum_{i=1}^{n+1} \frac{k_i}{r_i} D_i) \otimes \mathcal{O}_Y(\sum_{i=1}^{n+1} \frac{\lambda a_i k_i}{r_i} D_{n+2}'').
\]

Since

\[
K_W + \sum_{i=1}^{n+1} \frac{r_i - 1}{r_i} D_{i'}'' + D_{n+2}'' = \mu^* (K_X + \sum_{i=1}^{n+1} \frac{r_i - 1}{r_i} D_i) - \sum_{i=n''+1}^{n+1} \frac{\lambda a_i}{r_i} D_{n+2}''
\]

we have \( Rp \tilde{\mu} \tilde{\nu}^* L = 0 \) for \( p > 0 \), if \( \sum_{i=1}^{n+1} \frac{a_i k_i}{r_i} < - \sum_{i=n''+1}^{n+1} \frac{a_i}{r_i} \) by [1] Theorem 1.2.5. Thus if

\[
0 \leq \sum_{i=1}^{n+1} \frac{a_i k_i}{r_i} < - \sum_{i=n''+1}^{n+1} \frac{a_i}{r_i}
\]  

(4.1)

then we have \( F(L) = \mathcal{O}_X(\sum_{i=1}^{n+1} \frac{k_i}{r_i} D_i) \).

Let \( L' = \mathcal{O}_Y(\sum_{i=1}^{n+1} k_i D_i') \) be another invertible sheaf. We assume that both \( L \) and \( L' \) are in the range \([1,1]\). Since \( f \) is isomorphic in codimension 1, the natural homomorphism

\[
\text{Hom}(L', L) \to \text{Hom}(F(L'), F(L))
\]

is bijective. We shall prove that their higher Hom’s vanish on both \( X \) and \( Y \).
We have \( \mathcal{H}om(L', L)_Y = \mathcal{O}_Y(\sum_{i=1}^{n+1} \left( \frac{k_i - k'_i}{r_i} \right) D'_i) \) and

\[
\sum_{i=1}^{n+1} \frac{k_i - k'_i}{r_i} D'_i \equiv \left( \sum_{i=1}^{n+1} \frac{k_i - k'_i}{r_i} \right) D'_{n+1}.
\]

Since \( -\sum_{i=1}^{n+1} a_i \frac{k_i - k'_i}{r_i} > \sum_{i=n'+1}^{n+1} a_i \), we have

\[
-\sum_{i=1}^{n+1} a_i \frac{(k_i - k'_i)}{r_i} > \sum_{i=n'+1}^{n+1} \frac{a_i}{r_i} + \sum_{i=n'+1}^{n+1} \frac{r_i - 1}{r_i} = \sum_{i=n'+1}^{n+1} a_i.
\]

Since \( K_Y + \sum_{i=1}^{n'} D'_i \equiv \sum_{i=n'+1}^{n+1} D'_i \equiv (\sum_{i=n'+1}^{n+1} a_i) D'_{n+1} \) and \( D'_{n+1} \) is ample, we conclude that

\[
\mathcal{H}om^p(L', L) = H^p(Y, \mathcal{H}om(L', L)_Y) = 0
\]

for \( p > 0 \) by [7] Theorem 1.2.5.

Similarly, we have \( \mathcal{H}om(F(L'), F(L))_X = \mathcal{O}_X(\sum_{i=1}^{n+1} \left( \frac{k_i - k'_i}{r_i} \right) D_i) \) and

\[
\sum_{i=1}^{n+1} \frac{k_i - k'_i}{r_i} D_i \equiv -\left( \sum_{i=1}^{n+1} \frac{k_i - k'_i}{r_i} \right) D_{n+1}.
\]

Since \( \sum_{i=1}^{n+1} a_i \frac{(k_i - k'_i)}{r_i} > \sum_{i=n'+1}^{n+1} a_i \), we have

\[
\sum_{i=1}^{n+1} \frac{a_i}{r_i} \frac{(k_i - k'_i)}{r_i} > \sum_{i=n'+1}^{n+1} \frac{a_i}{r_i} - \sum_{i=1}^{n+1} a_i \frac{r_i - 1}{r_i}
\]

\[
\geq -\sum_{i=1}^{n'} \frac{a_i}{r_i} - \sum_{i=1}^{n'} a_i \frac{r_i - 1}{r_i} = -\sum_{i=1}^{n'} a_i.
\]

Since \( K_X + \sum_{i=n'+1}^{n+1} D_i \equiv -\sum_{i=1}^{n'} D_i \equiv (\sum_{i=1}^{n'} a_i) D_{n+1} \) and \( -D_{n+1} \) is ample, we conclude that

\[
\mathcal{H}om^p(F(L'), F(L)) = H^p(X, \mathcal{H}om(F(L'), F(L))_X) = 0
\]

for \( p > 0 \) by [7] Theorem 1.2.5. Therefore, the proof of the fully faithfulness of \( F \) is reduced to the following Lemma 4.3 by using [1].
(4) We interchange $X$ and $Y$, and use the notation of (2). The inequality $K_X + B \leq f^*(K_Y + C)$ implies that

$$\sum_{i=1}^{n} \frac{a_i}{r_i} \leq \frac{1}{r_n}.$$ 

Let $L = \mathcal{O}_X(\sum_{i=1}^{n+1} \frac{k_i}{r_i} D_i)$ be an invertible sheaf on $X$, where $k_i$ are integers. Since $f^*D'_i = D_i + a_i D_{n+1}$, we have

$$\bar{\mu}^*L = \mathcal{O}_W(\sum_{i=1}^{n+1} \frac{k'_i}{r'_i} D'_i) = \bar{\nu}^*\mathcal{O}_Y(\sum_{i=1}^{n} \frac{k_i}{r_i} D'_i) \otimes \mathcal{O}_W(-\sum_{i=1}^{n+1} \frac{a_i k'_i}{r'_i} D''_{n+1})$$

where we note that $a_{n+1} = -1$. Since

$$K_X + \sum_{i=1}^{n} \frac{r_i - 1}{r_i} D_i + D_{n+1} = f^*(K_Y + \sum_{i=1}^{n} \frac{r_i - 1}{r_i} D'_i) + \sum_{i=1}^{n} \frac{a_i}{r_i} D_{n+1}$$

we have $R^p \bar{\nu}_* \bar{\mu}^* L = 0$ for $p > 0$ if $-\sum_{i=1}^{n+1} \frac{a_i k'_i}{r'_i} < \sum_{i=1}^{n} \frac{a_i}{r_i}$. Thus if

$$0 \leq -\sum_{i=1}^{n+1} \frac{a_i k'_i}{r'_i} < \sum_{i=1}^{n} \frac{a_i}{r_i}$$

then we have $F(L) = \mathcal{O}_Y(\sum_{i=1}^{n} \frac{k'_i}{r'_i} D'_i)$.

Let $L' = \mathcal{O}_X(\sum_{i=1}^{n+1} \frac{k'_i}{r'_i} D_i)$ be another invertible sheaf, so that we have $\text{Hom}(L', L)_X = \mathcal{O}_X(\sum_{i=1}^{n+1} \frac{k_i - k'_i}{r_i} D_i)$. We assume that both $L$ and $L'$ are in the range $[1,2]$. Since we have $\sum_{i=1}^{n} \frac{a_i}{r_i} \leq \frac{1}{r_n}$, the homomorphism

$$\text{Hom}(L', L) \rightarrow \text{Hom}(F(L'), F(L))$$

is bijective.

We have

$$\sum_{i=1}^{n+1} \frac{k_i - k'_i}{r_i} D_i \equiv -\sum_{i=1}^{n+1} \frac{a_i}{r_i} D_{n+1}.$$ 

Since $-\sum_{i=1}^{n+1} \frac{a_i k'_i}{r'_i} < \sum_{i=1}^{n} \frac{a_i}{r_i}$, we have

$$-\sum_{i=1}^{n+1} \frac{(k_i - k'_i)}{r_i} < \sum_{i=1}^{n} \frac{a_i}{r_i} + \sum_{i=1}^{n} \frac{r_i - 1}{r_i} = \sum_{i=1}^{n} a_i.$$
Since $K_X + D_{n+1} \equiv -\sum_{i=1}^n D_i \equiv (\sum_{i=1}^n a_i)D_{n+1}$ and $D_{n+1}$ is ample, we conclude that

$$\text{Hom}^p(L', L) = H^p(X, \mathcal{H}om(L', L)_X) = 0$$

for $p > 0$. Therefore, $F$ is fully faithful by the following Lemma 4.4.

**Lemma 4.3.** The set of all the invertible sheaves on $\mathcal{Y}$ in the range 4.1 is a spanning class of the category $\mathcal{D}^b(\text{Coh}(\mathcal{Y}))$.

*Proof.* Let $\Omega$ be the set of all such invertible sheaves. We shall prove that the full subcategory $\mathcal{D}$ spanned by $\Omega$ coincides with $\mathcal{D}^b(\text{Coh}(\mathcal{Y}))$. Let $i_p$ $(1 \leq p \leq t)$ be integers such that $n'' < i_1 < \cdots < i_t \leq n + 1$ and $t < n - n''$. Let $i_0$ be an integer such that $n'' < i_0 \leq n + 1$ and $i_0 \neq i_p$ for any $p$. Let $S$ be the intersection of the Cartier divisors $\frac{1}{r_{i_p}}D'_{i_p}$ for $1 \leq p \leq t$ on $\mathcal{Y}$. We call $S$ a stratum. We have an exact Koszul complex

$$0 \rightarrow \mathcal{O}_Y(-\sum_{p=1}^t \frac{1}{r_{i_p}}D'_{i_p}) \rightarrow \cdots \rightarrow \bigoplus_{p=1}^t \mathcal{O}_Y(-\frac{1}{r_{i_p}}D'_{i_p}) \rightarrow \mathcal{O}_Y \rightarrow \mathcal{O}_S \rightarrow 0.$$

Let $k_i$ $(1 \leq i \leq n + 1, i \neq i_0)$ be any choice of integers, and let $k_{i_0}$ be an integer such that $-\frac{a_{i_0}}{r_{i_0}} > \sum_{i=1}^{n+1} \frac{a_i k_i}{r_i} \geq 0$. Then we have

$$-\sum_{i=n''+1}^{n+1} \frac{a_i}{r_i} > \sum_{i=1}^{n+1} \frac{a_i k_i}{r_i} - \sum_{p=1}^t \frac{a_{i_p} \epsilon_p}{r_{i_p}} \geq 0$$

if $\epsilon_p = 0, 1$. Therefore, $\mathcal{D}$ does not change if we add all the sheaves of the form $\mathcal{O}_S(\sum_{i=1}^{n+1} \frac{k_i}{r_i}D'_{i})$ to the set $\Omega$.

Assume that $t = n - n'' - 1$. Then $S$ is affine and $\mathcal{O}_S(\frac{1}{r_{i_0}}D'_{i_0}) \cong \mathcal{O}_S$. Therefore, $\mathcal{D}$ does not change if we add the invertible sheaves $\mathcal{O}_S(\sum_{i=1}^{n+1} \frac{k_i}{r_i}D'_{i})$ for all integers $k_i$ to the set $\Omega$. Hence any coherent sheaf whose support is contained in $S$ belongs to $\mathcal{D}$.

We claim that, for any staratum $S$, $\mathcal{D}$ does not change if we add the invertible sheaves $\mathcal{O}_S(\sum_{i=1}^{n+1} \frac{k_i}{r_i}D'_{i})$ for all integers $k_i$ to the set $\Omega$. Indeed, we proceed by the descending induction on $t$. Let $S' = S \cap \frac{1}{r_{i_0}}D'_{i_0}$. Then our claim follows from the following exact sequence

$$0 \rightarrow \mathcal{O}_S(-\frac{1}{r_{i_0}}D'_{i_0}) \rightarrow \mathcal{O}_S \rightarrow \mathcal{O}_{S'} \rightarrow 0.$$

Hence any coherent sheaf belongs to $\mathcal{D}$. ∎
Lemma 4.4. The set of all the invertible sheaves on $X$ in the range is a spanning class of $D^b(\text{Coh}(X))$.

Proof. The proof is similar to that of Lemma 4.3. □

Corollary 4.5. Let $X$ and $Y$ be quasi-smooth projective toric varieties, let $B$ and $C$ be effective toric $\mathbb{Q}$-divisors on $X$ and $Y$, respectively, whose coefficients are contained in the set $\{1 - 1/r | r \in \mathbb{Z}_{>0}\}$, and let $\mathcal{X}$ and $\mathcal{Y}$ be smooth Deligne-Mumford stacks attached to the pairs $(X, B)$ and $(Y, C)$, respectively. Let $f : X \to Y$ be a toric proper birational map which is log crepant in the sense that

$$g^*(K_X + B) = h^*(K_Y + C)$$

for toric proper birational morphisms from a common toric variety $g : Z \to X$ and $h : Z \to Y$ such that $f = h \circ g^{-1}$. Then there is an equivalence of triangulated categories

$$F : D^b(\text{Coh}(\mathcal{Y})) \to D^b(\text{Coh}(\mathcal{X})).$$

Proof. By with some additional argument due to Matsuki, $f$ is shown to be decomposed into a sequence of divisorial contractions and flips which are log crepant. □

Remark 4.6. (1) We note that the Fourier-Mukai functors for both divisorial contractions and flips are of the same type consisting of pull-backs and push-downs. Indeed, divisorial contractions and flips are of the same kind of operations from the view point of the Minimal Model Program though they look very different geometrically.

(2) In the situation of Theorem 4.2 (1), suppose that there is a third $\mathbb{Q}$-divisor $D$ on $X$ with standard coefficients such that $B \geq C \geq D$. Let $\mathcal{Z}$ be the stack corresponding to the pair $(X, D)$. Then there are fully faithful functors $F_1 : D^b(\text{Coh}(\mathcal{Z})) \to D^b(\text{Coh}(\mathcal{Y}))$, $F_2 : D^b(\text{Coh}(\mathcal{Y})) \to D^b(\text{Coh}(\mathcal{X}))$ and $F_3 : D^b(\text{Coh}(\mathcal{Z})) \to D^b(\text{Coh}(\mathcal{X}))$ as proved there. But we have $F_3 \not\cong F_2 \circ F_1$ in general.

(3) Let $X = \mathbb{C}^2$, $\mathcal{Z} = B_1 + B_2$ the union of the two coordinate lines, $f : Y \to X$ the blowing up at the singular point $B_1 \cap B_2$ of $\mathcal{Z}$, and $\mathcal{C} = B'_1 + B'_2 + C_3$ the union of the strict transforms and the exceptional divisor. Let $\mathcal{X}_n$ and $\mathcal{Y}_n$ be the stacks associated to the pairs $(X, \frac{1}{2n}(B_1 + B_2))$ and $(Y, \frac{1}{2n}(B'_1 + B'_2) + \frac{1}{n}C_3)$, respectively. Since $f^*(K_X + \frac{1}{2n}(B_1 + B_2)) = K_Y + \frac{1}{2n}(B'_1 + B'_2) + \frac{1}{n}C_3$, we have equivalences $\Phi_n : D^b(\text{Coh}(\mathcal{X}_n)) \to D^b(\text{Coh}(\mathcal{Y}_n))$
for each \( n \) by Theorem 4.2 (2). On the other hand, we have fully faithful functors \( \Psi_{X,n,n'} : D^b(\text{Coh}(\mathcal{X}_n)) \to D^b(\text{Coh}(\mathcal{X}_{n'})) \) and \( \Psi_{Y,n,n'} : D^b(\text{Coh}(\mathcal{Y}_n)) \to D^b(\text{Coh}(\mathcal{Y}_{n'})) \) for \( n < n' \) by Theorem 4.2 (1). We have to be careful that the following diagram is not commutative

\[
\begin{array}{ccc}
D^b(\text{Coh}(\mathcal{X}_n)) & \xrightarrow{\Phi_n} & D^b(\text{Coh}(\mathcal{Y}_n)) \\
\downarrow \Psi_{X,n,n'} & & \downarrow \Psi_{Y,n,n'} \\
D^b(\text{Coh}(\mathcal{X}_{n'})) & \xrightarrow{\Phi_{n'}} & D^b(\text{Coh}(\mathcal{Y}_{n'})).
\end{array}
\]

The reason is that the Serre functors, defined by using different invertible sheaves, are not compatible.

We conclude this paper with a remark on the non-commutative geometry as in [9]. We consider the situation of Theorem 4.2 (3) under the additional assumption that \( \mu^*(K_X + B) = \nu^*(K_Y + C) \).

Although the set of all invertible sheaves on \( Y \) in the range (4.1) is infinite, there are only finitely many isomorphism classes. Let \( R_Y \) be the direct sum of these representatives, and let \( A_Y = \text{Hom}(P_Y, P_Y) \) be the non-commutative ring of endomorphisms. We denote by \( \text{Mod}(A_Y) \) the abelian category of finitely generated right \( A_Y \)-modules.

**Proposition 4.7.** There is an equivalence of triangulated categories:

\[ D^b(\text{Coh}(\mathcal{Y})) \cong D^b(\text{Mod}(A_Y)). \]

**Proof.** By the proof of Theorem 4.2 (3), we have \( \text{Hom}^p(P_Y, P_Y) = 0 \) for \( p > 0 \) and the set \( \{P_Y\} \) is spanning. We claim that the functors

\[
G : D^b(\text{Coh}(\mathcal{Y})) \to D^b(\text{Mod}(A_Y)) \\
H : D^b(\text{Mod}(A_Y)) \to D^b(\text{Coh}(\mathcal{Y}))
\]

given by \( G(a) = R\text{Hom}(P_Y, a) \) and \( H(m) = m \otimes_{A_Y}^L P_Y \) are quasi-inverses each other. Indeed, we have \( G(P_Y) \cong A_Y \) and \( H(A_Y) \cong P_Y \). Since \( P_Y \) and \( A_Y \) respectively span \( D^b(\text{Coh}(\mathcal{Y})) \) and \( D^b(\text{Mod}(A_Y)) \), it follows that \( G \) and \( H \) are fully faithful by [1], hence quasi-inverses each other. \( \square \)
