Background: Chronic idiopathic urticaria (CIU) has a significant impact on patients’ quality of life.

Objective: The purpose of this study is to assess that impact and to compare differences by culture, gender, age or duration of treatment.

Methods: We used the modified chronic urticaria quality of life questionnaire, consisting of 15 questions. Over the course of 6 months, patients attending Immunology clinics at Campbelltown Hospital and private rooms in Australia and at the faculty of Medicine, University of Kelaniya in Sri Lanka were asked to fill out the questionnaires. We have obtained the data from 125 patients (43 Australian vs. 82 Sri Lankan). There were significantly more female patients \( (p < 0.01) \). The data was analysed using SAS.

Results: Overall, patients were affected mostly by itch and wheals and least affected by the side effects of treatments. Sri Lankan populations were more affected by wheals and by interference on activities, mood and food choices but were less affected by tiredness due to sleep disturbances \( (p < 0.01) \). Females were more affected by sleep disturbance \( (p < 0.05) \) while those older than 40 years of age were more impacted by tiredness and by the side effects from medications \( (p < 0.05) \), though the complaints themselves were mild. Those who suffered from CIU for more than 1 year were more affected by wheal, tiredness and irritability \( (p \leq 0.05) \).

Conclusion: The questionnaire highlighted some differences between patients attending Australian versus Sri Lankan outpatients. Significant differences were found in one third of parameters which include mood, sleep, daily activities and food choices.

Key words: Chronic urticaria; Quality of life; Australian population; Sri Lankan population; Cultural differences

INTRODUCTION

Chronic idiopathic urticaria (CIU) is a common condition, affecting 0.1% of the general population [1]. It is not life-threatening but several studies over the last decade have shown that it has a significant impact on quality of life (QoL) [2-4]. Its effect on QoL is comparable to that experienced by patients suffering from ischaemic heart disease with considerable loss of energy, sleep disturbance and emotional upset [2]. Compared to QoL in patients with respiratory allergy, CIU patients were more affected in physical functioning, pain perception and perceived health [3]. Compared to other dermatological conditions, the overall impact of CIU on QoL can be likened to acne and psoriasis [4]. More specifically, its physical discomfort and effect on daily
living activities are similar to those suffering from atopic dermatitis and are more severe than psoriasis [5].

Despite these facts, there are only a few studies that have specifically looked at QoL in CIU. This is particularly relevant given the primary goal of CIU treatment is symptom control and improvement in QoL. As patient perception of disease and QoL can vary in different cultural contexts, understanding particular aspects of QoL specific to a given culture may bring into focus areas that need greater attention. However, there is no study to our knowledge that has compared QoL in CIU in different cultural contexts.

Most of the studies done so far have used different types of questionnaires with a varying degree of specific questions for CIU. Generic tools such as SF-36 (a health status questionnaire) and Nottingham Health Profile have the advantage of allowing comparison with different conditions but they have a potential to underestimate specific aspects of QoL that are particularly affected by CIU. Two other studies comparing QoL in CIU vs. other dermatological conditions have employed either the dermatology life quality index (DLQI) or VQ-Dermato [4, 5]. DLQI has been used extensively in assessment of dermatological conditions with good internal consistency and reliability. It has the advantage of being more relevant to dermatological conditions while allowing it to compare CIU with other dermatological diseases but again, it is not specifically developed for CIU. Recently a new tool, chronic urticaria quality of life questionnaire (CU-QoL), has been devised with a good level of validity, internal consistency and reliability [6]. It is able to evaluate the specific QoL issues related to CIU and at the same time, it is simple to administer, taking only a few minutes to complete.

The purpose of this study is to assess the impact of CIU on QoL and to compare the differences in different cultural contexts, in particular, in Australian and Sri Lankan populations. It also looks at whether gender, age or the duration of treatment have any impact on QoL. As this study is looking at the QoL in the same disease but in different subgroups, it was felt that administering CU-QoL was more appropriate for the reasons outline above.

MATERIALS AND METHODS

Subjects

In the first half of 2008, patients with the diagnosis of CIU attending either public or private Immunology/Allergy Clinics in Sydney, Australia and the clinic in the faculty of Medicine, University of Kelaniya in Sri Lanka were asked to fill out the questionnaire. Diagnosis of CIU was made based on history and examination by attending specialists.
Impact of chronic urticaria in Australians and Sri Lankans

Questionnaire instruments

We have used the CU-QoL published by Baiardini et al. [6] with modifications (Fig. 1). A question on irritability was added as previous studies have indicated that CIU affects emotions and that this aspect needs to be explored further [2-5]. The questions on the use of cosmetics and limitations in choosing clothing materials were omitted as they were considered less relevant in our study populations. Indeed, in the original article by Baiardini et al. [6], these two questions ranked low in the overall impact. In addition, a question on nocturnal waking was also removed as there were already three questions pertaining to the effect of sleep disturbances. The questions on urticaria interfering with spare time and with social relationship were combined to form a question on recreational activities. The scales were increased from 0-3 to 0-6 as we felt that 0-3 scale would not capture varying degrees of discomfort experienced by patients. Score 0 was given when the patient was not affected and 6 was given when the patient was extremely affected.

Statistical analysis

Data was analysed using SAS version 9.1.3 (SAS Institute, USA). Non-parametric statistical methods were used as normality was not accepted within groups. Hence median rather than mean values were used to determine p-values although parametric tests returned similar p-values and reached the same conclusions anyway. A non-parametric alternative to a two sample t-test, Wilcoxon Mann-Whitney test, was used to ascertain significant differences. p-values ≤0.05 was considered statistically significant.

RESULTS

Demographics. Table 1 summarises the characteristics of the two study populations.

Questionnaire results. Overall, pruritus (median 5, mean 4.2) and wheals (median 5, mean 3.8) were the commonest complaints followed by CIU interfering with regular activities (median 4, mean 3.4), recreational activities (median 3, mean 3.1) and mood (median 3, mean 3.1). Patients were least affected by the side effects of treatments (median 0, mean 1.3) (Table 2, mean data not shown).

There were statistically significant differences noted between Australian and Sri Lankan patients in 5 out of 15 questions. The Sri Lankan population was more affected by wheals (median 5 vs. 4, \( p = 0.01 \)) and by its interferences with regular activities (median 4 vs. 3, \( p < 0.01 \)), mood (median 4 vs. 2, \( p < 0.01 \)) and food choices (median 3 vs. 1, \( p < 0.01 \)) but were less affected by tiredness due to sleep disturbances (median 1 vs. 3, \( p < 0.01 \)) when compared to the Australian population (Table 2).

Table 2. Median modified CU-QoL scores by nationality

| Practical problems                                      | Australian | Sri Lankan | p-value | Total |
|--------------------------------------------------------|------------|------------|---------|-------|
| Are you affected by itch?                              | 5.0        | 5.0        | 0.71    | 5.0   |
| Are you affected by wheals (welts)?                    | 4.0        | 5.0        | 0.01    | 5.0   |
| Are you affected by swelling (e.g. of lips or eyes)?   | 2.0        | 3.0        | 0.99    | 3.0   |

| Activities                                             |            |            |         |       |
|--------------------------------------------------------|------------|------------|---------|-------|
| Urticaria interferes with my regular activities at home or at work | 3.0        | 4.0        | < 0.01  | 4.0   |
| Urticaria interferes with my recreational activities   | 3.0        | 4.0        | 0.08    | 3.0   |
| Does urticaria affect your sleep?                      | 3.0        | 3.0        | 0.81    | 3.0   |
| Do you have difficulty falling asleep?                 | 3.0        | 1.0        | 0.14    | 1.5   |
| Do you feel tired during the day because of your bad night sleep? | 3.0        | 1.0        | < 0.01  | 1.0   |

| Mood                                                  |            |            |         |       |
|-------------------------------------------------------|------------|------------|---------|-------|
| Does urticaria affect your mood?                      | 2.0        | 4.0        | < 0.01  | 3.0   |
| Are you feeling irritable because of your symptoms?   | 3.0        | 4.0        | 0.69    | 3.0   |
| Do you feel embarrassed because of your condition?    | 3.0        | 1.0        | 0.13    | 2.0   |
| Are you embarrassed to go into public places?         | 2.0        | 1.0        | 0.42    | 1.0   |
| Do you put limits on your food choices because of urticaria? | 1.0        | 3.0        | < 0.01  | 3.0   |
| Do you have limits on your physical activity because of urticaria? | 1.0        | 0.0        | 0.36    | 0.0   |
| Are you affected by side effects from your medications?| 1.0        | 0.0        | 0.28    | 0.0   |

CU-QoL: chronic urticaria quality of life questionnaire.
Females were more affected in sleep, especially with difficulty falling asleep (median 2 vs. 1, \( p < 0.05 \)) but there were no differences in other parameters (Table 3). Those older than 40 years of age were more affected by tiredness due to poor sleep (median 2 vs. 1, \( p < 0.05 \)) and by the side effects of medications (median 1 vs. 0, \( p < 0.05 \)) though the complaints were mild. Patients who had CIU for longer than 1 year were more affected by itch (median 5 vs. 4, \( p = 0.01 \)), tiredness due to poor sleep (median 2 vs. 1, \( p < 0.05 \)) and irritability (4 vs. 2.5, \( p = 0.05 \)).

**DISCUSSION**

Previous studies [2, 5] have indicated that CIU has a significant impact on QoL with notable effects on sleep, energy levels and mood so it is not surprising that the present study revealed similar results. The Australian patient population reported more sleep disturbance leading to daytime tiredness when compared to the Sri Lankan population but in both groups, those with longer duration of CIU reported more sleep disturbance, tiredness and irritability.

Sri Lankan patients were more affected by wheals than their Australian counterparts. The reason for this is unclear and somewhat surprising as urticaria is usually less visible on darker skin. Cultural perception does not seem to play a major role in this as there was no significant difference in the level of embarrassment. Warmer climate in Sri Lanka may account for worsening wheals as urticaria is often exacerbated by heat. However, this alone does not provide an adequate explanation as other parameters such as itch were not increased. Alternatively, higher prevalence of helminth infections in Sri Lankan population with subsequent higher total IgE levels may play a role in worsening wheal formation. While there are reports of CIU associated with helminth infections, further studies will be required to clarify this issue [7, 8]. Sri Lankan patients were also more impacted by interference with regular activities and mood. The reasons for these are not apparent.

Sri Lankan populations were more inclined to limit food choices when compared to Australian patients. This may be due to a more prevalent assumption that CIU is due to food hypersensitivity in Sri Lanka. Alternatively, avoidance of certain common spicy foods in Sri Lanka that result in worsening symptoms by increasing body temperature may explain this phenomenon. While there are reports of CIU associated with helminth infections, further studies will be required to clarify this issue [7, 8]. Sri Lankan patients were also more impacted by interference with regular activities and mood. The reasons for these are not apparent.

| Practical problems                                      | Gender   | Age          | Duration of CU |
|--------------------------------------------------------|----------|--------------|----------------|

that the Australian group had more severe CIU so reported more sleep disturbance. Also, while duration of treatment has been documented, we did not document the specific drugs used in individuals. If more sedating antihistamines were used by one group compared to the other, differences in tiredness may be due to this rather than the disease. However, patients in both groups ranked side effects from medication as being minimal so this is a less likely explanation.

The role of food intolerance in CIU is an area where there may be significant culturally driven differences in perception. For instance, there is a common belief, based on observation, that hot, spicy foods worsen urticaria so it is not surprising that we detected a difference between the two patient populations regarding limitations on food choices.

There were some gender-based and age-based differences noted in QoL. Overall, females from both populations had more difficulty with falling asleep. Previous studies have indicated that women have a higher prevalence of sleep disturbances compared to men and this may account for this finding [9]. Older patients were more affected by tiredness and by the side effects of medications. Both of these complaints are generally more prevalent in aging populations and this may account for the differences. Those patients affected by CIU for a longer duration were more affected by itch, tiredness due to poor sleep, and irritability. Perhaps this is a reflection of disease severity as itch can both interfere with the quality of sleep and mood. This also illustrates the fact that patients who have this condition for a long time do not necessarily ‘get used to it’ or become less affected by it.

In conclusion, there are significant differences noted in one third of the response to questionnaires between Australian and Sri Lankan patient populations with CIU. Some of the differences may be explained by differences in cultural perception and environmental factors, but variation in disease severity and differences in treatment regimens may also contribute in part and need further exploration.
