Abstract

AIM
To explore the effect of alanine aminotransferase (ALT) on the performance of non-invasive fibrosis tests in chronic hepatitis B (CHB) patients.

METHODS
A total of 599 treatment-naive and biopsy-proven CHB patients were included in the study. The cohort was divided into the following three groups: Normal ALT (ALT ≤ 40), slightly elevated ALT (40 < ALT ≤ 80) and elevated ALT (ALT > 80). The diagnostic performance of five common non-invasive fibrosis tests for liver fibrosis (stages S2–4), including the aspartate aminotransferase (AST)-to-platelet (PLT) ratio index (APRI), fibrosis index based on 4 factors (FIB-4), King’s score, Forns index and gamma-glutamyl transpeptidase (GGT)-to-PLT ratio (GPR), were evaluated for each group.

RESULTS
Higher ALT levels were associated with higher non-
invasive fibrosis test scores. Patients with the same fibrosis stage but higher ALT levels showed higher non-invasive test scores. The areas under the receiver operating characteristics curves (AUROCs) of the non-invasive tests for prediction of ≥ S2 were higher for patients with ALT ≤ 40 U/L (range 0.705-0.755) and 40 < ALT ≤ 80 U/L (range 0.726-0.79) than for patients with ALT > 80 U/L (range 0.604-0.701). The AUROCs for predicting ≥ S3 and S4 were higher in patients with ALT ≤ 40 U/L (range 0.736-0.814 for ≥ S3, 0.79-0.833 for S4) than in patients with 40 < ALT ≤ 80 U/L (range 0.732-0.754 for ≥ S3, range 0.626-0.723 for S4) and ALT > 80 U/L (range 0.7-0.784 for ≥ S3, range 0.662-0.719 for S4). The diagnostic accuracy of the non-invasive tests decreased in a stepwise manner with the increase in ALT.

CONCLUSION
ALT has a significant effect on the diagnostic performance of non-invasive fibrosis tests. The ALT level should be considered before performing these non-invasive tests.

INTRODUCTION
Liver fibrosis is one of the main characteristics of chronic hepatitis B (CHB). Accurate assessment of liver fibrosis is vital for predicting disease progression and choosing optimal treatment timing. Liver biopsy (LB) is the current gold standard for evaluating the liver fibrosis stage. However, repeatedly utilizing LB in patients is very difficult because of its invasiveness and complications[1]. Therefore, non-invasive methods have been developed to assess liver fibrosis when the risk-benefit trade-off does not favor a LB[2].

According to the EASL-ALEH Clinical Practice Guidelines, non-invasive methods were recently divided into serum biomarkers and liver stiffness (LS) measurements[3]. Because of their high applicability (> 95%) and good interlaboratory reproducibility, serum biomarkers are widely used in clinical practice[3]. Over the past few years, many convenient non-invasive fibrosis tests have been established, including the aspartate aminotransferase (AST)-to-platelet (PLT) ratio index (APRI)[4] and the fibrosis index based on 4 factors (FIB-4)[5]. Moreover, the APRI and FIB-4 were recommended by the WHO for evaluation of liver fibrosis in resource-limited regions[6]. However, most non-invasive fibrosis tests have been developed primarily based on chronic hepatitis C patients, and their use in assessing liver fibrosis in CHB patients is controversial[7-9]. Therefore, more data should be collected regarding the use of these established non-invasive tests to predict liver fibrosis in CHB patients. Recently, Lemoine et al[10] constructed the gamma-glutamyl transpeptidase (GGT)-to-PLT ratio (GPR) model based on CHB patients, but its diagnostic performance assessing liver fibrosis varied among different studies[11,12].

Alanine aminotransferase (ALT) is considered an accurate and valuable routine indicator of liver inflammation. Many studies have reported the influence of serum ALT levels on LS[13,14]. According to the EASL-ALEH Clinical Practice Guidelines for CHB[3], LS measurements should be interpreted in patients with an elevated ALT level and should not be used in patients with ALT levels more than 10 times the upper limit of normal (ULN). However, no report has investigated the effects of changes in CHB patients’ serum ALT levels on the diagnostic performances of these non-invasive tests. For these reasons, the aim of this study was to explore the effect of ALT on the diagnostic performance of non-invasive fibrosis tests in CHB patients.

MATERIALS AND METHODS

Patients
The study included treatment-naive CHB patients who underwent LB from 2012-2017 in the Shengjing Hospital affiliated with China Medical University. CHB was defined as hepatitis B surface antigen-positive lasting at least six months. The exclusion criteria were as follows: (1) coinfection with human immunodeficiency virus; (2) other liver disease (other viral hepatitis, autoimmune liver disease, drug hepatitis and liver failure); (3) significant alcohol intake (> 20 g/d for women and > 30 g/d for men) for more than 5 years; (4) tumor; (5) liver transplantation; and (6) hematological diseases.

The study was approved by the Medical Ethics Committee of Shengjing Hospital of China Medical University and was performed in accordance with the guidelines of the 1975 Declaration of Helsinki. Written informed consent for the LB was obtained from all patients.
Laboratory data and histology
Laboratory data, including the blood test results (PLT), liver biochemistry (ALT; aspartate aminotransferase, AST; alkaline phosphatase, ALP; γ-glutamyltransferase, GGT and cholesterol), HBV serological marker levels (HBsAg; hepatitis B envelope antigen, HBeAg; antibodies against HBsAg, anti-HBs; antibodies against HBeAg, anti-HBe and antibodies against HBcAb, anti-HBc), blood coagulation (international normalized ratio, INR) and HBV DNA levels, were recorded for all included patients.

All liver specimens were a minimum of 10 mm with at least five portal tracts. A histopathological assessment was performed by two expert pathologists who were unaware of the patient’s clinical characteristics. According to Scheuer’s classification score, liver fibrosis was classified from 0 to 4[17].

Non-invasive fibrosis tests and calculation formulas
Non-invasive prediction methods and calculation formulas were applied for the CHB patients according to the original reported formulas with the original cut off values for the APRI, FIB-4, Forns index[18], GPR and King’s score[19]. The formulas of these non-invasive tests are as follows:

\[
\text{APRI} = \frac{\text{AST(ULN)/PLT (10}^9 / \text{L)} \times 100}{\text{ALT(ULN)} / \text{PLT (10}^9 / \text{L)} \times \left(\frac{1}{2}\right)}
\]

\[
\text{FIB-4} = \text{Age (year)} \times \frac{\text{AST(ULN)}}{\text{PLT (10}^9 / \text{L)} \times \left(\frac{1}{2}\right)}
\]

\[
\text{GPR} = \frac{\text{GGT(ULN)/PLT (10}^9 / \text{L)} \times 100}{\text{ALT(ULN)} / \text{PLT (10}^9 / \text{L)}}
\]

King’s score = Age × AST × INR/PLT

Forns index = 7.811 - 3.131 × ln(PLT count) + 0.781 × ln(GGT) + 3.467 × ln(age) - 0.014 × (cholesterol)

Statistical analysis
Continuous and abnormal variables are expressed as the median (interquartile range, IQR), and categorical data are expressed as the frequency and percentage; the data were compared using the Kruskal-Wallis test. Spearman’s rank correlation was used to analyze the liver fibrosis stages and the non-invasive test results. The diagnostic performances of these non-invasive tests were assessed by receiver operating characteristic (ROC) curve analysis. The diagnostic performances of each test for the assessment of significant fibrosis, advanced fibrosis and cirrhosis are described as the areas under the receiver operating characteristics curve (AUROCs) with 95% confidence intervals (95%CIs) and the diagnostic accuracy. All P-values were 2-sided, and any value of P < 0.05 was considered statistically significant. The data analysis was performed using SPSS, version 22.0 (SPSS Inc., Chicago, IL, United States) and the GraphPad Software, version 7.0 (GraphPad Prism Inc., San Diego, CA, United States).

RESULTS

Study population
From January 2012 to July 2017, 1262 biopsy-proven patients with liver disease were assessed in the study. Among them, 575 patients were excluded according to the exclusion criteria, and 88 patients were excluded because of insufficient liver tissue and clinical data. Finally, 599 CHB patients were included in the cohort (Figure 1). The median (IQR) age of the patients was 37 (29-44) years, and 349 (58.3%) patients were male. In all, 96 (16%) patients had significant fibrosis (≥ S2), 54 (9%) had advanced fibrosis (≥ S3), and 38 (6.3%) had cirrhosis (S4). The clinical parameters and stages of fibrosis are shown in Table 1.

Effects of ALT on clinical factors in patients with CHB
To detect the effect of ALT on non-invasive fibrosis tests, the patients were divided into the following three groups: normal ALT (ALT ≤ 40), slightly elevated ALT (40 < ALT ≤ 80) and elevated ALT (ALT > 80). The baselines for these three groups are shown in Table 1.

The ALT levels were significantly correlated with AST (r = 0.878), GGT (r = 0.565), HBV DNA (r = 0.363) and HBsAg (r = 0.137) (P < 0.05 for all). Significant negative associations were also found between the ALT level and age (r = -0.206) and male sex (r = -0.195) (P < 0.05 for all). Other clinical factors, including cholesterol, INR and PLT, had no association with the ALT level (P > 0.05 for all).

Effects of ALT on the fibrosis scores of the non-invasive fibrosis tests
In addition, the ALT levels were positively correlated with the fibrosis stage (r = 0.141), APRI (r = 0.762), GPR (r = 0.545), King’s score (r = 0.615), FIB-4 (r = 0.125) and Forns index (r = 0.107) (P < 0.05 for all). Increasing ALT levels were significantly associated with an increased fibrosis stage (P < 0.05).

The patients with ALT > 80 had the highest fibrosis scores, whereas the lowest fibrosis scores were observed for patients with ALT ≤ 40. In general, CHB patients with higher ALT levels had significantly higher fibrosis scores on the non-invasive tests (P < 0.05 for all) except for the Forns index (P = 0.081) (Table 1). Moreover, the patients with higher ALT levels showed significantly higher fibrosis scores on the non-invasive tests than those with lower ALT levels at the same stage of liver fibrosis (P < 0.05 for all) except for Forns index and FIB-4 at S1, S2 and S4 (Table 2).

Effects of ALT on the diagnostic performance of the non-invasive fibrosis tests
A summary of the diagnostic performances of these non-invasive tests, including the AUROCs, 95%CIs and P-values in the different ALT groups for the prediction of significant fibrosis, advanced fibrosis and cirrhosis, are shown in Table 3 and Figure 2.

Generally, the AUROCs of the non-invasive tests for the prediction of ≥ S2 in CHB patients with ALT ≤ 40 U/L (range 0.705-0.755) and 40 < ALT ≤ 80 U/L (range 0.726-0.79) were higher than those in patients with ALT > 80 U/L (range 0.604-0.701). For the ≥ S3 and
S4 predictions, the AUROCs of the non-invasive tests in CHB patients with ALT $\leq 40$ U/L (range 0.736–0.814 for $\geq$ S3, range 0.79–0.833 for S4) were higher than those in patients with 40 < ALT $\leq 80$ U/L (range 0.732–0.754 for $\geq$ S3, range 0.626–0.723 for S4) and ALT > 80 U/L (range 0.7–0.784 for $\geq$ S3, range 0.662–0.719 for S4).

### Table 1 Baseline characteristics of the subjects

| Characteristics | Total group ($n = 599$) | ALT $\leq 40$ group ($n = 272$) | 40 < ALT $\leq 80$ group ($n = 190$) | ALT > 80 group ($n = 137$) | $P$-value |
|-----------------|-------------------------|-------------------------------|------------------------------------|----------------------------|----------|
| Age (yr)        | 37 (29, 44)             | 39 (31.25, 46)               | 37.5 (28, 43.25)                   | 34 (28, 40.5)              | < 0.001  |
| Male (%)        | 349 (58.3)              | 131 (48.2)                   | 130 (68.4)                         | 88 (64.2)                  | < 0.001  |
| ALT (U/L)       | 44 (28, 76)             | 26 (31.33)                   | 56 (48, 66)                        | 127 (95, 218.5)            | < 0.001  |
| AST (U/L)       | 32 (24, 48)             | 24 (20, 28)                  | 36 (31, 42)                        | 70 (55, 115.5)             | < 0.001  |
| GGT (U/L)       | 25 (17, 41)             | 19 (14, 25)                  | 30 (20, 41.25)                     | 48 (30, 78)                | < 0.001  |
| Cholesterol (mmol/L) | 4.31 (3.94, 4.96) | 4.35 (3.86, 4.95)            | 4.24 (3.75, 4.95)                  | 4.34 (3.84, 4.99)          | 0.732    |
| PLT ($\times 10^9$/L) | 182 (150, 217)   | 184 (155, 223)               | 177.5 (145.5, 212)                 | 180 (149, 215)             | 0.215    |

| S (%)           |                         |                              |                                    |                            |          |
| S0              | 264 (44.1)              | 128 (47.1)                   | 80 (42.1)                          | 56 (40.9)                  |          |
| S1              | 147 (24.5)              | 73 (26.8)                    | 53 (27.9)                          | 21 (13.3)                  |          |
| S2              | 96 (16)                 | 35 (12.9)                    | 29 (15.3)                          | 32 (23.4)                  |          |
| S3              | 54 (9)                  | 19 (7.0)                     | 18 (9.5)                           | 17 (12.4)                  |          |
| S4              | 38 (6.3)                | 17 (6.3)                     | 10 (5.3)                           | 11 (8.0)                   |          |
| Stage S0-1 fibrosis | 411 (68.6)          | 201 (73.9)                   | 133 (70)                           | 77 (56.2)                  | 0.001    |
| Stage S2-4 fibrosis | 188 (31.4)           | 71 (26.1)                    | 57 (30)                            | 60 (43.8)                  |          |
| APRI            | 0.53 (0.38, 0.86)       | 0.38 (0.3, 0.49)             | 0.61 (0.44, 0.8)                   | 1.16 (0.88, 1.93)          | < 0.001  |
| FIB-4           | 1.02 (0.72, 1.47)       | 1.02 (0.72, 1.37)            | 0.96 (0.66, 1.55)                  | 1.22 (0.82, 1.79)          | < 0.001  |
| GFR             | 0.22 (0.15, 0.38)       | 0.16 (0.11, 0.23)            | 0.24 (0.17, 0.38)                  | 0.42 (0.25, 0.68)          | < 0.001  |
| King’s score    | 6.77 (4.31, 11.49)      | 4.89 (3.54, 7.03)            | 7.18 (4.58, 11.58)                 | 13.04 (9.81, 27.15)        | < 0.001  |
| Forns index     | 6.48 (5.44, 7.51)       | 6.33 (5.37, 7.37)            | 6.57 (5.51, 7.69)                  | 6.65 (5.57, 7.57)          | 0.081    |

Data are expressed as the n (%) or median (interquartile range, IQR). ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; GGT: Gamma-glutamyl transferase; PLT: Platelet; S: Stage of fibrosis; GPR: Gamma-glutamyl transpeptidase (GGT)-to-platelet ratio; APRI: Aspartate aminotransferase (AST)-to-platelet (PLT) ratio index; FIB-4: Fibrosis index based on 4 factors; INR: International sensitivity index.

### Figure 1 Flow chart of the study population selection.

HCC: Hepatocellular carcinoma; HIV: Human immunodeficiency virus; HBV: Hepatitis B virus.
The relationship between the diagnostic accuracy and serum ALT was also evaluated using the cut off value as the original threshold. For the S2 prediction, the diagnostic accuracies of the APRI (lower cut off value 0.5), APRI (higher cut off value 1.5), Forns index (lower cut off value 4.2), Forns index (higher cut off value 6.9), GPR and King’s score were 75.74%, 73.90%, 33.09%, 68.75%, 81.62% and 77.21%, respectively, for patients with ALT $\leq 40$ U/L; 62.63%,72.63%, 35.79%, 66.84%, 71.05% and 72.11%, respectively, for patients with 40 $< ALT \leq 80$ U/L; and 45.99%, 66.42%, 46.72%, 58.39%, 61.31% and 43.80%, respectively, for patients with ALT $> 80$ U/L.

For the S3 prediction, the diagnostic accuracies of GPR (using the lower cut off value 2.0) and APRI (using the higher cut off value 2.0) were 93.01%, 93.75%, 93.01% and 94.44%, respectively, for patients with ALT $\leq 40$ U/L; 83.68%, 94.21%, 84.74% and 87.37%, respectively, for patients with 40 $< ALT \leq 80$ U/L; and 42.34%, 77.37%, 65.69% and 61.31%, respectively, for patients with ALT $> 80$ U/L.

The above results indicate that the non-invasive tests for the prediction of liver fibrosis ($\geq S2$, $\geq S3$ and S4) exhibited the highest diagnostic accuracy for patients in the ALT $\leq 40$ U/L group and the lowest diagnostic accuracy for patients in the ALT $> 80$ U/L group, except for the Forns index (using the lower cut off values) for the S2 prediction and APRI (using the higher cut off values) for the S4 prediction (Table 3 and Figure 3). The diagnostic accuracy of the non-invasive tests decreased in a stepwise manner with the increase in the serum ALT level.

### Table 2

| Characteristics | APRI | FIB-4 | GPR | King’s score | Forns index |
|-----------------|------|-------|-----|--------------|-------------|
| S0 (n)          | 128  | 128   | 128 | 128          | 128         |
| ALT $\leq 40$   | 0.37 (0.26-0.44) | 0.88 (0.65-1.26) | 0.15 (0.1-0.2) | 4.3 (3.09-5.89) | 6.06 (5.04-7.03) |
| 40 $< ALT \leq 80$ | 0.31 (0.29-0.35) | 0.77 (0.57-1.15) | 0.22 (0.14-0.31) | 5.91 (4.18-8.08) | 6.16 (4.91-7.04) |
| ALT $> 80$      | 1.02 (0.85-1.5) | 0.97 (0.74-1.52) | 0.29 (0.22-0.48) | 11.62 (7.99-18.36) | 6.27 (5.36-7.26) |

Data are expressed as the median (interquartile range, IQR); ALT: Alanine aminotransferase; S: Stage of fibrosis; GPR: Gamma-glutamyl transpeptidase (GGT)-to-platelet ratio; APRI: Aspartate aminotransferase (AST)-to-platelet (PLT) ratio index; FIB-4: Fibrosis index based on 4 factors.

### Effects of ALT on the diagnostic accuracy of the non-invasive fibrosis tests

The relationship between the diagnostic accuracy and serum ALT was also evaluated using the cut off value as the original threshold. For the $\geq S2$ prediction, the diagnostic accuracies of the APRI (lower cut off value 0.5), APRI (higher cut off value 1.5), Forns index (lower cut off value 4.2), Forns index (higher cut off value 6.9), GPR and King’s score were 75.74%, 73.90%, 33.09%, 68.75%, 81.62% and 77.21%, respectively, for patients with ALT $\leq 40$ U/L; 62.63%,72.63%, 35.79%, 66.84%, 71.05% and 72.11%, respectively, for patients with 40 $< ALT \leq 80$ U/L; and 45.99%, 66.42%, 46.72%, 58.39%, 61.31% and 43.80%, respectively, for patients with ALT $> 80$ U/L.
D iscussion

In this study, we evaluated the diagnostic performances of five convenient non-invasive tests for liver fibrosis among a large cohort of treatment-naive CHB patients with different ALT levels. To the best of our knowledge, this study is the first to thoroughly analyze the effect of ALT on the diagnostic performance and accuracy of non-invasive tests in CHB patients. The results showed that elevated serum ALT levels negatively affected the diagnostic performance of the non-invasive fibrosis tests. These non-invasive fibrosis tests showed a better diagnostic accuracy in CHB patients with normal ALT levels than in patients with abnormal ALT levels.

One important finding of our study was that CHB patients with higher ALT levels showed significantly higher fibrosis scores in the non-invasive tests even at the same liver fibrosis stage. The result demonstrated that non-invasive tests could overestimate liver fibrosis in some CHB patients with elevated ALT. In other words, patients who had elevated ALT with no or mild fibrosis would be considered to have significant fibrosis, advanced fibrosis or cirrhosis. For example, the GPR, which had the highest AUROCs for the non-invasive test to predict cirrhosis in the study, showed that 6/272 (2.21%) CHB patients with normal ALT, 19/190 (10%) patients with slightly elevated ALT and 41/137 (29.9%) patients with elevated ALT would be misdiagnosed (i.e., approximately 10% of CHB patients with slightly elevated ALT and 30% of patients with elevated ALT...
would be misclassified as having cirrhosis). ALT flares often occur during the progression of CHB, especially for patients with acute or active hepatitis. Thus, the effect of ALT should be considered when assessing liver fibrosis using non-invasive tests.

To detect the effect of ALT on non-invasive tests, we compared the diagnostic performance and accuracy of the non-invasive tests in different ALT groups. In this study, most AUROCs (11/15) for prediction of ≥S2, ≥S3 or S4 by the non-invasive tests were greater than 0.75 in patients with normal ALT but less than 0.75 (12/15) in patients with elevated ALT. Thus, the tests showed a slightly higher performance for the CHB patients with normal ALT than for the patients with elevated ALT.

To further examine the effect of ALT on the non-invasive tests, an overall analysis of AUROCs should be conducted in patients with different ALT levels. However, the performance of AUROCs varies among different fibrosis tests, etiologies and cohorts [10,11]. Therefore, evaluating the diagnostic performance of non-invasive fibrosis tests using one AUROC from one stage is difficult. A simple, comprehensive and systematic assessment is more reasonable and acceptable; thus, the AUROC grading system for the prediction of liver fibrosis was developed. In this study, we comprehensively evaluated the effect of ALT on five common non-invasive fibrosis tests based on the AUROC grading system. The ability of the AUROCs to predict liver fibrosis decreased with the increase in the ALT level. Additionally, studies have reported that elevated ALT can influence the diagnostic performances of non-invasive fibrosis tests, although most of these studies have focused on ≥S2 or S4 [18-20]. In our study, the effect of ALT on the AUROCs of the

![Figure 2](image-url)
non-invasive fibrosis tests among three fibrosis stages (≥ S2, ≥ S3 and S4) were all included. The AUROCs for prediction of ≥ S2, ≥ S3 and S4 were more stable in patients with ALT ≤ 40 U/L.

Similarly, the best diagnostic accuracy of the non-invasive tests was found in patients with a normal ALT level, whereas the accuracy was lowest in patients with elevated ALT. The diagnostic accuracy of these non-invasive tests decreased in a stepwise manner with the increase in the ALT level. In patients with normal ALT, the AUROCs of these non-invasive tests for the diagnosis of cirrhosis ranged from 0.79 to 0.833 with a diagnostic accuracy range from 93.01% to 94.44% when the cut off value was the original threshold. However, for CHB patients with elevated ALT, the AUROCs of these non-invasive tests for the diagnosis of cirrhosis ranged from 0.662 to 0.719 with a diagnostic accuracy range from 42.34% to 77.37% when the cut off value was the original threshold. From the above results, we can infer that the diagnostic performances of the non-invasive tests were less reliable in CHB patients with elevated ALT levels.

The phenomenon may contribute to liver inflammation. Liver fibrosis is the process by which damaged hepatocytes are repaired and is a product of dysregulated inflammation in chronic viral hepatitis[21]. Liver inflammation can influence LS[14]. Moreover, systemic inflammation can serve as a degenerating factor for intrahepatic hypertension in cirrhosis[22]. The serum ALT level is the most direct and valuable marker that reflects liver inflammation in the clinic. To some extent, more severe liver inflammation is associated with greater ALT elevation[23], which has more impact on the non-invasive tests. This phenomenon may be the main reason why the non-invasive tests showed better diagnostic performances in patients with normal ALT.

This study had several limitations. First, this study was a single-center retrospective study. A multicenter study will be performed in the future. Second, we compared only some of the more convenient non-invasive diagnostic tests. Other non-invasive diagnostic tests and LS measurements will be evaluated in future studies.

In conclusion, the ALT level has a significant effect on the diagnostic performance and accuracy of non-invasive fibrosis tests. The ALT level should be considered before performing these non-invasive tests.

ARTICLE HIGHLIGHTS

Research background

Because of their high applicability and good interlaboratory reproducibility, many convenient non-invasive fibrosis tests have been established. Many studies have reported the influence of alanine aminotransferase (ALT) levels on liver stiffness (LS) measurements. However, no report has investigated the effects of changes in the serum ALT levels of chronic hepatitis B (CHB) patients on the diagnostic performances of these non-invasive tests.

Research objectives

To explore the effect of serum ALT on the diagnostic performances of non-invasive fibrosis tests in CHB patients.

Research methods

A total of 599 treatment-naive and biopsy-proven CHB patients were included.
in the study. The cohort was divided into the following three groups: normal ALT (ALT $\leq 40$), slightly elevated ALT (40 < ALT $\leq 80$) and elevated ALT (ALT > 80). The diagnostic performances of five common non-invasive fibrosis tests for liver fibrosis (stages S2-4), including the aminotransferase (AST)-to-platelet (PLT) ratio index (APRI), fibrosis index based on 4 factors (FIB-4), King’s score, Forns index and gamma-glutamyl transpeptidase (GGT)-to-PLT ratio (GPR), were evaluated for each group.

**Research results**
Higher ALT levels were associated with higher non-invasive test scores for the prediction of liver fibrosis. Patients with the same fibrosis stage but higher ALT levels showed higher non-invasive test scores. The areas under the receiver operating characteristics curves (AUROCs) of the non-invasive tests for the $\geq$ S2 prediction were higher in patients with ALT $\leq 40$ U/L (range 0.705-0.755) and 40 < ALT $\leq 80$ U/L (range 0.726-0.79) than in patients with ALT > 80 U/L (range 0.604-0.701). The AUROCs for the $\geq$ S3 and S4 predictions were higher in patients with ALT $\leq 40$ U/L (range 0.736-0.814 for $\geq$ S3, 0.790-0.833 for S4) than in patients with 40 < ALT $\leq 80$ U/L (range 0.732-0.754 for $\geq$ S3, range 0.626-0.723 for S4) and ALT > 80 U/L (range 0.7-0.784 for $\geq$ S3, range 0.662-0.719 for S4). The diagnostic accuracy of the non-invasive fibrosis tests decreased in a stepwise manner with the increase ALT level.

**Research conclusions**
ALT has a significant effect on the diagnostic performances of non-invasive fibrosis tests.

**Research perspectives**
The ALT level should be considered before performing these non-invasive tests.
