Hovering UAV-Based FSO Communications: Channel Modelling, Performance Analysis, and Parameter Optimization

Jin-Yuan Wang, Member, IEEE, Yang Ma, Rong-Rong Lu, Jun-Bo Wang, Member, IEEE, Min Lin, Member, IEEE, and Julian Cheng, Senior Member, IEEE

Abstract—Relay-assisted free-space optical (FSO) communication systems are exploited as a means to mitigate the limiting effects of the turbulence induced atmospheric scintillation. However, conventional ground relays are stationary, and their optimal placement is not always feasible. Due to their mobility and flexibility, unmanned aerial vehicles (UAVs) provide new opportunities for FSO relaying systems. In this paper, a hovering UAV-based serial FSO decode-and-forward relaying system is investigated. In the channel modelling for such a system, four types of impairments (i.e., atmospheric loss, atmospheric turbulence, pointing error, and link interruption due to angle-of-arrival fluctuation) are considered. Based on the proposed channel model, a tractable expression for the probability density function of the total channel gain is obtained. Closed-form expressions of the link outage probability and end-to-end outage probability are derived. Asymptotic outage performance bounds for each link and the overall system are also presented to reveal insights into the impacts of different impairments. To improve system performance, we optimize the beam width, field-of-view and UAVs’ locations. Numerical results show that the derived theoretical expressions are accurate to evaluate the outage performance of the system. Moreover, the proposed optimization schemes are efficient and can improve performance significantly.

Index Terms—FSO communications, outage probability, parameter optimization, relay, UAV.

I. INTRODUCTION

Recently, free-space optical (FSO) communications has attracted considerable attention to overcome the spectrum congestion problem [2], [3], because unlike the radio frequency (RF) wireless communications, FSO communications are unlicensed, directional, immune to electromagnetic interference, and not easily intercepted. Nevertheless, it is widely acknowledged that the terrestrial FSO signal is impaired by three important factors including atmospheric loss, atmospheric turbulence, and pointing error, which are all distance-dependent [4]. Moreover, the transceivers in FSO communications are limited by the strict requirement of line-of-sight (LoS) alignment [5]. These disadvantages lead to the development of the relay-assisted FSO communications [6], whereby relays are placed properly between the source and the destination to improve system performance and reliability. However, affected by the obstacles (such as lakes, mountains and buildings), the optimal positions to deploy relays may not be always feasible, and thus novel relaying schemes should be exploited.

To revolutionize the commonly-employed relaying network architectures, the unmanned aerial vehicle (UAV) based relaying scheme was proposed for FSO communications [7]. Compared with the conventional terrestrial relays, UAV-based relays have the intrinsic advantages of finding better communication environment and establishing the LoS links by adjusting positions dynamically. With the perfect combination of FSO communications and UAVs, the UAV-based FSO communication system is currently gaining significant attention, which is regarded as a promising technology in many fields, such as emergency response and military operation [8]–[10]. It is expected that employing UAVs in FSO communication systems will inspire promising and innovative applications for future communication systems.

For UAV-based FSO relaying systems, accurate channel modeling, tractable performance indicator expressions and efficient parameters optimization methods are of vital importance. Several analytical models for hovering UAV based FSO
communications were proposed \[11]\). In \[12]\), the alignment and stability analyses for inter-UAV communications were presented. In \[13]\), the ergodic sum rate for a UAV-based relay network with mixed RF/FSO channel was derived, and the joint effects of the atmospheric loss, the atmospheric turbulence, and the geometric and misalignment loss on the FSO channel were considered. In \[14]\), the throughput for a UAV-based mixed FSO/RF system with a buffer constraint was analyzed. Note that the effects of the angle-of-arrival (AoA) fluctuations of due to orientation deviations of hovering UAVs were not considered in \[11]- \[14]\). By considering the non-orthogonality of the laser beam and the random fluctuations of the UAV’s orientation and position, a novel channel model was proposed for UAV-based FSO communications \[15]\). In \[16]\), the FSO channel impaired by weak turbulence, pointing error and AoA fluctuation was established. By considering the AoA fluctuation and pointing error, the outage performance of an FSO communication system operating on high-altitude airborne platforms was investigated \[17]\). Recently, by jointly considering the effects of atmospheric attenuation, atmospheric turbulence, pointing error and link interruption due to AoA fluctuation, a novel statistical channel model for hovering UAV-based FSO communications was derived \[18]\). In \[19]\), by taking into account the effect of nonzero boresight pointing error, an extended model is established for UAV-based FSO communications. However, due to the large number of complex functions and operators, the derived expressions \[18]\), \[19]\) are cumbersome, and intuitive insights cannot easily be obtained for system design. To facilitate the parameter optimization, we are motivated to develop tractable channel models and theoretical expressions.

For parameter optimizations, there exist two fundamental tradeoffs in UAV-based FSO communications \[16]\), \[17]\), \[20]\), \[21]\). First, the beam width balances the fading of pointing error and the strength of received signal. That is, increasing beam width will mitigate the impact of pointing error, but it also reduces the strength of the received signal. Second, the selection of field-of-view (FoV) involves a tradeoff between AoA fluctuation and received noise. In other words, increasing the value of FoV can reduce the impact of AoA fluctuation but increase the received noise as well. For network optimizations, the deployment or trajectory of UAVs can be designed to take full advantage of their ultra-flexibilities. Such topics have been studied in open literature. In \[22]\)– \[24]\), the performance indicators like system throughput, network coverage, energy efficiency, and task completion time were optimized to find the optimal static locations or trajectory of UAVs. When designing the UAVs’ trajectory, most prior solutions rely on simplified channel models that are based on either the assumption that LoS link always exists or the LoS statistic model. However, in reality, the LoS link may be obstructed by some obstacles (such as mountains and buildings). In other words, the LoS link may not always be available in practical systems. Therefore, the existence of the LoS link should be considered in the parameter optimization process \[25]\). Consequently, an important question arises: How to efficiently find LoS link and obtain satisfied system performance for UAV-based FSO communication systems with obstacles? Under the obstacle scenario, the UAV’s location was optimized within a feasible region bounded by the minimum accepted elevation angles of source and destination \[26]\. Note that the AoA fluctuation in \[26]\. is ignored, the considered lognormal distributed turbulence is only suitable for weak turbulence, and the feasible region limits the deployment of UAVs. Therefore, the parameter optimization problem in UAV-based FSO communications should be further investigated.

Motivated by the aforementioned discussions, this paper focuses on a hovering UAV-based serial relaying FSO communication system, and further investigates the channel modeling, performance analysis and parameter optimization problems. The contributions of this paper are summarized as follows:

- **Channel modeling**: The considered FSO system involves three kinds of links, i.e., the ground-to-UAV (GU) link, the UAV-to-UAV (UU) link, and the UAV-to-ground (UG) link. For each link, the effects of atmospheric loss, atmospheric turbulence, pointing error and link interruption due to AoA fluctuation are jointly considered. Different from \[18]\), we consider the independence of four impairments, and obtain a simple and tractable expression for the probability density function (PDF) of the total channel gain, which can be effectively used for performance analysis. The accuracy of the derived PDF is verified in Section V.

- **Performance analysis**: Based on the derived PDF of the total channel gain, the closed-form expressions of the link outage probability and the end-to-end outage probability are derived. Through asymptotic analysis, the asymptotic bounds of the link outage probability and the end-to-end outage probability are then obtained. Furthermore, insights about the derived expressions are also provided. Numerical results verify the accuracy of the derived theoretical expressions, and these expressions can be directly utilized to evaluate system performance rapidly without time-intensive simulations.

- **Parameter optimization**: To further improve the system performance, the beam width, the FoV and the UAVs’ locations are optimized. Specifically, the minimum beam width is derived first, and the actual beam width of each link should be adjusted to be larger than or equal to the minimum value. Then, the FoV is optimized by minimizing the end-to-end outage probability with the beam width constraint, and the asymptotically optimal FoV is derived by solving a nonlinear equation. Finally, under the obstacle scenario, the locations of UAVs are optimized by solving a minimization problem. Then, the problem is transformed to a min-max problem, which can be effectively solved by using the embedded function \textit{“fmincon” in MATLAB} \[23]\). Numerical results verify the effectiveness of the proposed parameter optimization schemes.
A. Received Signal Model

Here, the intensity modulation and direct detection is employed and the on-off keying (OOK) is used as the modulation scheme. For simplification, the source node is denoted by node 0, the relay nodes are denoted by nodes 1, 2, …, N, and the destination node is denoted by node N + 1. In the considered system, there are N + 1 links, and the ith link is built by node i − 1 and node i. Mathematically, the received electrical signal at node i in the ith link is given by

\[ y_i = R_h x_i + n_i, \quad i = 1, \cdots, N + 1, \quad (1) \]

where R is the optoelectronic conversion factor of the PD at node i; \( x_i \) is the transmitted optical signal of node i − 1; \( h_i \) is the channel gain of the ith link, and \( n_i \) is the signal-independent additive white Gaussian noise having mean zero and variance \( \sigma_{n,i}^2 \), i.e., \( n_i \sim \mathcal{N}(0, \sigma_{n,i}^2) \). The transmitted optical signal is taken as symbols drawn equal-probably from the OOK constellation such that \( x_i \in \{0, 2P_1\} \), and \( P_1 \) is the average transmitted optical power per link, which is related to the total transmit optical power \( P \) by \( P_t = P/(N + 1) \). At each receiver, the background noise is assumed to be the dominant noise source, and the noise variance is a quadratic function with respect to the FoV of the receiver \([18]\), i.e.,

\[ \sigma_{n,i}^2 = \Lambda \theta_{\text{FoV},i}^2, \quad (2) \]

where \( \Lambda \) is a coefficient related to the wavelength, bandwidth of the optical filter, spectral radiance and lens area. \( \theta_{\text{FoV},i} \) is the receiver’s FoV at node i.

B. Channel Model

There are three types of links in the considered system, i.e., the GU link, the UU links, and the UG link. Actually, the first link is the GU link, the \( (N + 1) \)th link is the UG link, and all other links (i.e., from the second link to the Nth link) belong to the UU links. For all the links, the total channel gain \( h_i \) can be formulated as a product of four impairments, i.e.,

\[ h_i = h_i^{(1)} h_i^{(a)} h_i^{(\text{pe})} h_i^{(\text{aoa})}, \quad i = 1, \cdots, N + 1, \quad (3) \]

where \( h_i^{(1)} \) is the atmospheric loss, \( h_i^{(a)} \) is the atmospheric turbulence, \( h_i^{(\text{pe})} \) is the pointing error, and \( h_i^{(\text{aoa})} \) is the link interruption due to AoA fluctuation. Inspired by the ideas in \([17, 18]\) and \([25]\), three typical adjustable parameters (i.e., beam width, FoV, and link distance) are considered to be different in each link for the sake of the system parameter optimization, and the other parameters are assumed to be the same in all \( N + 1 \) links unless otherwise stated. In the following, the statistical characteristic of the four impairments will be analyzed, respectively.

1) Atmospheric loss: Referring to \([23]\), the atmospheric loss \( h_i^{(1)} \) is determined by the exponential Beers-Lambert law as

\[ h_i^{(1)} = \exp(-Z_i \Phi), \quad i = 1, \cdots, N + 1, \quad (4) \]

where \( Z_i \) is the distance of the ith link, and \( \Phi \) is the atmospheric attenuation coefficient related to visibility.
2) Atmospheric turbulence: For the atmospheric turbulence, the Gamma-Gamma fading model is used here since its distribution is in close agreement with measurements under various turbulence conditions. Therefore, the PDF of \( h_i^{(a)} \) is given by [29]
\[
f_{h_i^{(a)}}(h_i^{(a)}) = \frac{2(\alpha_i/\beta_i)^{\alpha_i/\beta_i}}{\Gamma(\alpha_i)\Gamma(\beta_i)} (h_i^{(a)})^{\alpha_i/\beta_i - 1} \times K_{\alpha_i - \beta_i} \left( 2\sqrt{\alpha_i/\beta_i \cdot h_i^{(a)}} \right), \quad i = 1, \ldots, N + 1, \tag{5}
\]
where the parameters \( \alpha_i \) and \( \beta_i \) related to large-scale and small-scale eddies are given by
\[
\begin{align*}
\alpha_i &= \exp \left( \frac{0.49\pi^2}{1 + 1.11\sigma_R^{2, i}} \right) - 1, \\
\beta_i &= \exp \left( \frac{0.51\pi^2}{1 + 0.69\sigma_R^{2, i}} \right) - 1,
\end{align*}
\tag{6}
\]
where \( \sigma_R^{2, i} = 1.23 C_n^2 k_i^2 / 6 Z_i^{11/6} \) is the Rayleigh variance related to the link distance \( Z_i \), \( C_n^2 \) is the index of refraction structure parameter of atmosphere, and \( k = 2\pi/\lambda \) is the optical wavelength number with \( \lambda \) being the wavelength.

3) Pointing error: Fig. 4 shows the Gaussian beam footprint at receiver aperture, where the beam is orthogonal to the receiver lens plane. We consider a circular detection aperture of radius \( r_{a,i} \) at node \( i, \ i = 1, \ldots, N + 1 \). The radial displacement vector from the receiving aperture center to the beam center is expressed as \( r_{a,i} = [x_{a,i}, y_{a,i}] \), which results from three different vectors: i) the displacement vector induced by the transmitter’s orientation deviation \( r_{\theta,i} = [x_{\theta,i}, y_{\theta,i}] \), ii) the displacement vector induced by the transmitter’s position deviation \( r_{r,i} = [x_{r,i}, y_{r,i}] \), and iii) the displacement vector induced by the receiver’s position deviation \( r_{s,i} = [x_{s,i}, y_{s,i}] \). Consequently, the displacements located along the horizontal axe and the vertical axe at the detector plane are, respectively, given by
\[
\begin{align*}
x_{d,i} &= x_{i} + x_{\theta,i} + x_{r,i} \\
y_{d,i} &= y_{i} + y_{r,i} + y_{s,i}.
\end{align*}
\tag{7}
\]
According to the central limit theorem, the position and orientation deviations follow Gaussian distributions as they result from numerous random events [18].

a) UU links: For these links, both \( x_{r,i} \) and \( x_{r,i} \) follow the same Gaussian distribution with mean zero and variance \( \sigma_P^{2, u} \), i.e., \( x_{r,i} \sim N(0, \sigma_P^{2, u}) \). Moreover, \( x_{\theta,i} = Z_i \tan \theta_{\theta,i} \sim N(0, \sigma_{\theta,P}^{2, u}) \). This indicates that \( x_{\theta,i} \sim N(0, \sigma_{\theta,P}^{2, u}) \). Similarity, the distribution of \( y_{d,i} \) can also be analyzed. As a result, \( x_{d,i}, y_{d,i} \sim N(0, 2\sigma_P^{2, u} + Z_i^2 \sigma_{\theta,P}^{2, u}) \).

b) GU link: For the first link, \( \theta_{\theta,1} \) is zero. The variances of position deviation \( x_{r,1} \) is assumed to be zero-mean Gaussian distribution with variance \( \sigma_P^{2, g} \), i.e., \( x_{r,1} \sim N(0, \sigma_P^{2, g}) \). Moreover, we can obtain \( x_{r,1} \sim N(0, \sigma_P^{2, g}) \). Therefore, \( x_{d,1}, y_{d,1} \sim N(0, \sigma_P^{2, g} + \sigma_{\theta,P}^{2, g}) \).

c) UG link: Referring to the analysis for GU and UU links, we can obtain \( x_{r,N+1} \sim N(0, \sigma_P^{2, g}) \), \( x_{r,N+1} \sim N(0, \sigma_P^{2, g}) \), \( x_{r,N+1} \sim N(0, \sigma_P^{2, g}) \), and \( x_{r,N+1} \sim N(0, \sigma_P^{2, g}) \).
where \( \theta_{tx,i} \) and \( \theta_{ty,i} \) are the horizontal and vertical misalignment orientations of the transmitter in the \( i \)th link. Similarly, \( \theta_{tx,i} \) and \( \theta_{ty,i} \) represent the horizontal and vertical orientation deviations of the receiver. Therefore, \( \theta_{n,i}, \ i = 1, \ldots, N + 1 \) is Rayleigh-distributed, i.e.,

\[
f_{\theta_{n,i}}(\theta_{n,i}) = \frac{\theta_{n,i}}{m_i \sigma_{\text{angle},u}^2} \exp\left(-\frac{\theta_{n,i}^2}{2m_i \sigma_{\text{angle},u}^2}\right), \theta_{n,i} \geq 0, \tag{12}
\]

where \( m_i \) varies with the type of links and is given by

\[
m_i \triangleq \begin{cases} 1, & i = 1 \text{ or } N + 1 \\ 2, & i = 2, \ldots, N \end{cases}.
\tag{13}
\]

We focus on the main lobe of the airy pattern, which has the most power. The width of the main lobe is approximately equal to 2.4\( \lambda \), which is much smaller than the typical detector size [31]. Consequently, a reasonable consideration is the zero-one distribution that describes whether the incident laser is located on the receiving FoV or not [32]. Mathematically, given a fixed FoV, the link interruption (i.e., \( h_i^{(\text{aoa})} = 0 \)) occurs if \( \theta_{n,i} > \theta_{\text{FoV},i} \), and the maximum signal power (i.e., \( h_i^{(\text{aoa})} = 1 \)) is collected otherwise. Therefore, the corresponding PDF of \( h_i^{(\text{aoa})} \) is given by

\[
f_{h_i}^{(\text{aoa})}(h_i) = \exp\left(-\frac{\theta_{\text{FoV},i}^2}{2m_i \sigma_{\text{angle},u}^2}\right) \delta(h_i) + \left[1 - \exp\left(-\frac{\theta_{\text{FoV},i}^2}{2m_i \sigma_{\text{angle},u}^2}\right)\right] \delta(h_i - 1),
\]

\[
i = 1, \ldots, N + 1.
\tag{14}
\]

### III. OUTAGE PERFORMANCE ANALYSIS

In this section, the overall statistical characteristic of the FSO channel is analyzed. Then, the link outage probability and the end-to-end outage probability are derived. Finally, the asymptotic behaviors of the outage probabilities are studied. Some insights are provided as well.

#### A. Overall Channel Statistical Characteristic

For the four impairments in \( \mathbf{3} \), \( h_i^{(l)} \) and \( h_i^{(a)} \) are obviously independent and also independent of \( h_i^{(\text{pe})} \) and \( h_i^{(\text{aoa})} \). Although the orientation deviations of the transmitters (i.e., \( \theta_{tx,i} \) and \( \theta_{ty,i} \)) contribute to the pointing error and the AoA fluctuation simultaneously, the correlation between \( h_i^{(\text{pe})} \) and \( h_i^{(\text{aoa})} \) is weak when \( \theta_{\text{FoV},i} \gg \sigma_{\text{angle},u} \). The reason is provided as follows. Note that \( \sigma_{\text{angle},u} \) is the standard deviation of \( \theta_{tx,i} \) and \( \theta_{ty,i} \). When \( \theta_{\text{FoV},i} \gg \sigma_{\text{angle},u} \), compared with \( r_{tx,i} \) and \( r_{ty,i} \), the impact of \( r_{\theta_{tx,i}} \simeq [Z_{\theta_{tx,i}}, Z_{\theta_{ty,i}}] \) in Fig. 2 on pointing error is weak. This indicates that the transmitter’s orientation misalignment is weakly correlated with pointing error when \( \theta_{\text{FoV},i} \gg \sigma_{\text{angle},u} \). Moreover, when \( \theta_{\text{FoV},i} \gg \sigma_{\text{angle},u} \), \( \theta_{tx,i} \) and \( \theta_{ty,i} \) have little effect on \( \theta_{n,i} \), and thus the transmitter’s orientation misalignment and the AoA fluctuation are also weakly correlated. Consequently, the four impairments in \( \mathbf{3} \) can be approximated as independent variables. Specially, for the GU link, the pointing error and the AoA fluctuation are no longer relevant since orientation deviations of the source node are approximately zero, and these four impairments are practically independent.

According to the above analysis, the PDF of \( h_i \) is approximated as

\[
f_{h_i}(h_i) \simeq \int_0^{+\infty} \frac{1}{h_i^{(l)} h_i^{(a)}} f_{h_i}^{(\text{aoa})}(h_i) f_{h_i}^{(\text{pe})}(h_i) dh_i^{(l)},
\tag{15}
\]

where \( h_i^{(l)} \triangleq h_i^{(l)} h_i^{(a)} h_i^{(\text{pe})} \). By solving (15), we derive the PDF of \( h_i \) and state the result in the following theorem.

**Theorem 1:** For the UAV-based FSO communication system, the PDF of the overall channel gain \( h_i \) is approximated as

\[
f_{h_i}(h_i) \simeq \exp\left(-\frac{\theta_{\text{FoV},i}^2}{2m_i \sigma_{\text{angle},u}^2}\right) \delta(h_i) + \left[1 - \exp\left(-\frac{\theta_{\text{FoV},i}^2}{2m_i \sigma_{\text{angle},u}^2}\right)\right] \frac{\alpha_i \beta_i \zeta_i^2}{A_i h_i^{(l)} (\Gamma(\alpha_i) \Gamma(\beta_i))} \times \prod_{N=1}^{3.3} \left[1 - \frac{\alpha_i \beta_i \zeta_i^2}{A_i h_i^{(l)}} \right] \zeta_i^2 - 1, \alpha_i - 1, \beta_i - 1.
\tag{16}
\]

**Proof:** See Appendix A.

To verify the accuracy of the approximated PDF expression in **Theorem 2**, we provide Fig. 4 in Section V. As can be seen, the approximate PDF in (16) is tight as long as \( \theta_{\text{FoV},i} \gg 5\sigma_{\text{angle},u} \), which justifies the proposed approximation.

#### B. Link Outage Probability

1) **Exact expression:** The outage probability is an important metric to evaluate the performance of the FSO communication system. The outage probability of the \( i \)th link \( p_i \) is expressed as the probability that the instantaneous SNR \( \Upsilon_i \) falls below the specified threshold \( \Upsilon_{\text{th},i} \), i.e.,

\[
p_i = \Pr(\Upsilon_i < \Upsilon_{\text{th},i}) = \Pr(h_i < h_{\text{th},i}),
\tag{17}
\]
where the corresponding threshold of the channel gain is

\[ h_{th,i} = \sqrt{\frac{\gamma_{th} \sigma_{angle,i}^2}{2R_i^2 P_t^2}} = \frac{\theta_{FoV,i}}{R_i P_t} \sqrt{\frac{\gamma_{th} N}{2}}. \]  

(18)

The exact expression of (17) is provided in the following theorem.

**Theorem 2:** For the UAV-based FSO communication system, the exact expression of the link outage probability \( p_i \), \( i = 1, ..., N+1 \) is given by

\[ p_i = \text{exp} \left(-\frac{\theta_{FoV,i}^2}{2m_i \sigma_i^2} \right) + \left[1 - \text{exp} \left(-\frac{\theta_{FoV,i}^2}{2m_i \sigma_i^2} \right) \right] \]

\[ \times \frac{\zeta_i^2}{\Gamma(\alpha_i) \Gamma(\beta_i)} \left[\frac{\alpha_i \beta_i}{\theta_{FoV,i}^2 A_i h_i^{(l)} R_{th,i} \sqrt{\gamma_{th} N}} \right] \left(1, \frac{\zeta_i^2+1}{\zeta_i^2, \alpha_i, \beta_i, 0} \right) \]  

(19)

where \( m_i \) is given by (13).

**Proof:** See Appendix [13].

2) **Asymptotic bound:** For large transmit power \( P_t \), the asymptotic bound of the link outage probability is given in the following theorem.

**Theorem 3:** For the UAV-based FSO communication system, the asymptotic bound of the link outage probability \( p_{\text{bound},i} \), \( i = 1, ..., N+1 \) for large transmit power \( P_t \) is given by

\[ p_{\text{bound},i} = \text{exp} \left(-\frac{\theta_{FoV,i}^2}{2m_i \sigma_i^2} \right). \]  

(20)

**Proof:** See Appendix [13].

**Remark 1:** In Theorem 3, the asymptotic bound (20) varies with \( \theta_{FoV,i} \) and \( m_i \). From (13), it is known that \( m_i = 1 \) for the UG/GU link, while \( m_i = 2 \) for the UU links. Given a fixed \( \theta_{FoV,i} \) for all the links, the asymptotic bound (20) for the UU links is larger than that for the GU/GU link, the asymptotic bound (20) for the UU link is the same as that for the GU link, which indicates that the UU links achieve the worst asymptotic outage performance, and the GU link and the UG link achieve the same asymptotic outage performance.

**C. End-to-end Outage Probability**

1) **Exact expression:** For DF relaying, outage of each intermediate link may lead to the outage of the relaying system. Therefore, the end-to-end outage probability is given by

\[ P_{\text{out}} = 1 - \prod_{i=1}^{N+1} (1 - p_i). \]  

(21)

Then, the end-to-end outage probability is obtained in the following theorem.

**Theorem 4:** For the UAV-based FSO communication system, the exact expression of the end-to-end outage probability \( P_{\text{out}} \) is expressed as

\[ P_{\text{out}} = 1 - \prod_{i=2}^{N} \left[1 - \text{exp} \left(-\frac{\theta_{FoV,i}^2}{2m_i \sigma_i^2} \right) \right] \times \frac{1}{\Gamma(\alpha_i) \Gamma(\beta_i)} \left[\frac{\alpha_i \beta_i}{\theta_{FoV,i}^2 A_i h_i^{(l)} R_{th,i} \sqrt{\gamma_{th} N}} \right] \left(1, \frac{\zeta_i^2+1}{\zeta_i^2, \alpha_i, \beta_i, 0} \right) \]  

(22)

**Proof:** The proof is straightforward by submitting (19) into (21).

2) **Asymptotic bound:** Due to the impact of the intermediate links performance bound in (20), the corresponding system performance is also limited by AoA fluctuation when the transmitted power is large. The asymptotic bound for the end-to-end outage probability is given in the following theorem.

**Theorem 5:** For the UAV-based FSO communication system, the asymptotic bound of the end-to-end outage probability \( P_{\text{bound}} \) for large transmit power \( P_t \) is given by

\[ P_{\text{bound}} = 1 - \prod_{i=2}^{N} \left[1 - \text{exp} \left(-\frac{\theta_{FoV,i}^2}{2m_i \sigma_i^2} \right) \right] \times \frac{1}{\Gamma(\alpha_i) \Gamma(\beta_i)} \left[\frac{\alpha_i \beta_i}{\theta_{FoV,i}^2 A_i h_i^{(l)} R_{th,i} \sqrt{\gamma_{th} N}} \right] \left(1, \frac{\zeta_i^2+1}{\zeta_i^2, \alpha_i, \beta_i, 0} \right) \]  

(23)

**Proof:** The proof is straightforward by substituting (20) into (21).

**Remark 2:** It is worth mentioning that the asymptotic bound \( P_{\text{bound}} \) in (23) deteriorates with the increase of the number of relays \( N \). Interestingly, increasing relay number worsens the outage performance when the system outage performance has attained the bound in (23).

**IV. PARAMETER OPTIMIZATIONS**

In this section, the key parameter optimizations for the UAV-based FSO communications are investigated. Specifically, the beam width, the FoV, and the UAV locations are optimized.

**A. Beam Width Adjustment**

Since hovering UAVs have larger deviations of the position and orientation than fixed ground platforms, pointing error in UAV-based links is more severe, hence the adjustment for beam width is especially important to improve the diversity order gain and outage performance for different communication conditions.

In (10), the ratio between the squared equivalent beam width and displacement variance is \( \zeta_i^2 = \frac{w^2 \sigma_i^2}{\sqrt{2} \sigma_i^2} \approx \frac{\sigma^2_{\text{eq}}}{3/2}, \) \( \sigma_{\text{eq}} \) in (5). \( \beta_i \) denotes the parameters related to small-scale eddy in atmospheric turbulence. According to (30) and (33), it can be known that the condition \( \zeta_i^2 < \beta_i \) represents that pointing error becomes dominant in relation to atmospheric turbulence in the \( \alpha \)th link. Since the turbulence parameter \( \beta_i \), which is related to the atmospheric condition,
cannot be chosen arbitrarily, adjusting beam width \( w_{z,i} \) to satisfy \( \zeta_i^2 \geq \beta_i \) is an appropriate measure. By letting \( \zeta_i^2 = \beta_i \), the minimum value of received beam width in the \( i \)th link is given by

\[
\omega_{z,i}^{\min} = \sqrt{\frac{4\beta_i\sigma_{z,i}^2}{3}} = \frac{3}{2\sqrt{2}}. \tag{24}
\]

Here, to avoid the severe impairment of pointing error, the beam width of each link in the FSO relaying system should satisfy

\[
\omega_{z,i} \geq \omega_{z,i}^{\min}, \quad i = 1, \ldots, N + 1. \tag{25}
\]

It is noteworthy to mention that the power received at fixed-size detector reduces with an increase of the beam width. Consequently, excessive increase of the beam width is also inadvisable.

B. FoV Optimization With the Beam Width Constraint

Due to the asymptotic bound \( \mathcal{B} \), the achievable end-to-end outage probability is limited. Therefore, after determining the minimum beam width, the FoV optimization problem should be considered to minimize the end-to-end outage probability, i.e.,

\[
\min_{\theta_{\text{FoV},1}, \ldots, \theta_{\text{FoV},N+1}} P_{\text{out}} \quad \text{s.t.} \quad \omega_{z,i} \geq \omega_{z,i}^{\min}, \quad i = 1, \ldots, N + 1. \tag{26}
\]

Since FoV adjustment of one link does not affect the other links, problem \( \mathcal{B} \) is reduced to optimizing FoV of each link individually, i.e.,

\[
\min_{\theta_{\text{FoV},i}} p_i \quad \text{s.t.} \quad \omega_{z,i} \geq \omega_{z,i}^{\min}. \tag{27}
\]

Considering the complexity of the exact link outage probability and the demand of practical FSO communications, we optimize the system performance for large \( P_t \). By substituting \( \mathcal{A} \) and \( \mathcal{B} \) into \( \mathcal{C} \), we obtain the link outage probability for large \( P_t \) with respect to \( \theta_{\text{FoV},i} \) as

\[
p_i \approx L(\theta_{\text{FoV},i}^2 + \Theta) \left[ 1 - L(\theta_{\text{FoV},i}^2) \right] (\theta_{\text{FoV},i})^{\beta_i}, \tag{28}
\]

where \( L(\theta_{\text{FoV},i}^2) \) and \( \Theta \) are defined as

\[
L(\theta_{\text{FoV},i}^2) = \exp \left( -\frac{\theta_{\text{FoV},i}^2}{2m_i\sigma_{\text{angle,i}}^2} \right), \quad \Theta = \frac{\zeta_i^2(\alpha_i - \beta_i)}{1(\alpha_i\beta_i)(\zeta_i^2 - \beta_i)\beta_i} \left( \frac{\alpha_i\beta_i}{A_ih_i^0} \right)^{-\beta_i} R \cdot \frac{1}{\sqrt{2\pi}} \beta_i. \tag{29}
\]

By taking derivative of \( \mathcal{A} \) with respect to \( \theta_{\text{FoV},i} \) and setting it to be zero, we obtain the following nonlinear equation

\[
m_i\Theta\sigma_{\text{angle,i}}^2\beta_i(\theta_{\text{FoV},i})^{\beta_i-2} \left[ 1 - L(\theta_{\text{FoV},i}^2) \right] + \Theta(\theta_{\text{FoV},i})^{\beta_i} L(\theta_{\text{FoV},i}^2) - L(\theta_{\text{FoV},i}^2) = 0. \tag{30}
\]

In this paper, the asymptotically optimal \( \theta_{\text{FoV},i} \) is updated to match different communication conditions by numerically solving \( \mathcal{C} \).

C. UAV Location Optimization

To improve the reliability of the end-to-end link, the UAVs’ positions can be optimized. To avoid the undesirable bound of AoA fluctuation (i.e., eq. \( \mathcal{B} \)), the FoV of each receiver is typically set to be a large fixed value. In this subsection, we assume that the FoV is sufficiently large so that the AoA fluctuation is neglectable.

Here, we consider an FSO relaying system with \( N \) UAVs and \( N_0 \) obstacles. To facilitate the optimization, all UAVs are assumed to be located at the same height. For all UAVs, the two-dimensional coordinates in the XY plane are optimized. Without loss of generality, the positions of UAVs are set to be \( (x_i, y_i), i = 1, \ldots, N \). Moreover, \( (x_0, y_0) \) and \( (x_{N+1}, y_{N+1}) \) are the coordinates of source node and destination node, respectively. Due to the existence of obstacles, the UAVs cannot be deployed on the positions of obstacles. An indicator function \( f_n(x_i, y_i, x_{i+1}, y_{i+1}) \) is used to indicate whether the \( i \)th link is block by the \( n \)th obstacle. Specifically, if the \( n \)th obstacle blocks the \( i \)th link, \( f_n(x_i, y_i, x_{i+1}, y_{i+1}) \geq 0 \), otherwise \( f_n(x_i, y_i, x_{i+1}, y_{i+1}) < 0 \). Here, the UAV location optimization problem can be formulated as

\[
\min_{x_1, y_1, \ldots, x_N, y_N} P_{\text{out}} \quad \text{s.t.} \quad f_n(x_i, y_i, x_{i+1}, y_{i+1}) < 0, \quad i = 0, 1, \ldots, N; n = 1, 2, \ldots, N_0. \tag{31}
\]

To solve the optimization problem, we assume that the atmospheric turbulence is dominant in relation to the pointing error (i.e., \( \zeta_i^2 > \beta_i, i = 1, \ldots, N + 1 \)), and the FoV \( \theta_{\text{FoV},i} \) is large. With these assumptions, the expression \( \mathcal{C} \) can be further written as

\[
p_i \approx \frac{\zeta_i^2\Gamma(\alpha_i - \beta_i)}{\Gamma(\alpha_i)\Gamma(\beta_i)(\zeta_i^2 - \beta_i)\beta_i} \left( \frac{\alpha_i\beta_i}{A_ih_i^0} \right)^{\beta_i} R \left( \frac{1}{2} \right)^{\beta_i} P_t^{-\beta_i}. \tag{32}
\]

We assume that the \( i_{\text{max}} \)th link is the longest with parameters \( a_{i_{\text{max}}} \) and \( \beta_{i_{\text{max}}} \). Since the parameter \( \beta_i \) decreases monotonically with an increase of the \( i \)th link distance, we have

\[
\lim_{P_t \to \infty} \frac{1 - \prod_{i=1}^{N+1} (1 - p_i)}{p_{i_{\text{max}}}} = \lim_{P_t \to \infty} \sum_{i=1}^{N+1} p_i = \lim_{P_t \to \infty} \sum_{i=1}^{N+1} a_iP_t^{-\beta_i} = 1, \tag{33}
\]

which indicates that the system outage probability is determined by the performance of the link having the maximum distance. Therefore, for a large value of \( P_t \), problem \( \mathcal{C} \) can
be transformed into
\[
\min_{x_1, y_1, \ldots, x_N, y_N} \max\{Z_1, Z_2, \ldots, Z_N\}
\]
\[
\text{s.t. } f_n(x_i, y_i, x_{i+1}, y_{i+1}) < 0 \\
i = 0, 1, \ldots, N; n = 1, 2, \ldots, N_0,
\]
(34)
where \(Z_i = \sqrt{(x_i - x_{i+1})^2 + (y_i - y_{i+1})^2}\) is the distance of the \(i\)th link. To solve problem (34) effectively, the grouping optimization or multi-variate optimization can be used, which can be implemented by using the embedded function “fmincon” in MATLAB.

\[\sigma_{p,u} = \sigma_{p,g} = 10 \text{ cm}, \text{ the standard deviation of UAV and ground displacement} \]

### V. Numerical Results

In this section, some numerical results will be presented to support the theoretical claims made in previous sections. Unless stated otherwise, the default values of the parameters used for simulations are given by \(\lambda = 1550 \text{ nm}, C_n^2 = 5 \times 10^{-14} \text{ m}^{-2/3}, R = 0.9, \Phi = 1 \text{ km}^{-1}, \sigma_n^2 = 6.4 \times 10^{-14}\) corresponding to \(\theta_{\text{FoV},i} = 8 \text{ mrad}, \text{ receiver lens radius } r_a = 5 \text{ cm}, \text{ the standard deviation of UAV and ground displacement}\)

\[\gamma_{\text{th}} = 10 \text{ dB}\]
Moreover, the GU link achieves the same asymptotic outage link achieves the comparable performance to the UG link. As shown in Fig. 6, the UU link achieves the maximum link outage probability, and the GU also be found in Fig. 6. As shown in Fig. 6, the UU link conclusions in Fig. 5, some other interesting insights can also be found in Fig. 6. As shown in Fig. 6, the UU link achieves the maximum link outage probability, and the GU link achieves the comparable performance to the UG link. Moreover, the GU link achieves the same asymptotic outage probability under different turbulence conditions when \( \theta_{\text{FoV},i} = 8 \) mrad, \( w_z = 2 \) m and \( Z = 250 \) m. For comparison, the asymptotic bound (23) in \textit{Theorem 5} is also presented. In this simulation, the obstacles are not considered, and \( N \) UAV nodes are uniformly deployed between the source node and the destination node. For small \( P_t \), the end-to-end outage probability performance does not improve with the increase of \( P_t \) or with the decrease of \( \sigma^2_{R_j} \). For large \( P_t \), the values of link outage probabilities tend to stable values, which are independent of the average transmitted optical power and the turbulence condition. Moreover, the stable values approach the asymptotic bound (20). This verifies the accuracy of (20) in \textit{Theorem 7}. Moreover, it should be emphasized that all analytical results in Fig. 5 present close agreement with Monte-Carlo simulation results, and the accuracy of the derived expression (19) in \textit{Theorem 2} is verified.

Fig. 6 compares the link outage performance for different kinds of links when \( \theta_{\text{FoV},i} = 5 \) mrad, \( \sigma^2_{R_j} = 1 \), \( w_z,i = 2 \) m and \( Z_i = 250 \) m. In addition to obtaining the similar conclusions in Fig. 5 some other interesting insights can also be found in Fig. 6. As shown in Fig. 6, the UU link achieves the maximum link outage probability, and the GU link achieves the comparable performance to the UG link. Moreover, the GU link achieves the same asymptotic outage performance as the UG link, and the asymptotic bound of the UU link is always larger than that of the UG/GU link. These insights verify the analysis in \textit{Remark 1}

Fig. 7 shows the end-to-end outage probability versus the average transmitted optical power for different numbers of relays when \( \theta_{\text{FoV},i} = 6 \) mrad, \( w_z,i = 2 \) m and the distance between source and destination nodes \( Z_{SD} = 2 \) km. For comparison, the asymptotic bound (23) in \textit{Theorem 5} is also presented. In this simulation, the obstacles are not considered, and \( N \) UAV nodes are uniformly deployed between the source node and the destination node. For small \( P_t \), the end-to-end outage probability performance improves with the increase of \( P_t \) or \( N \). However, at large \( P_t \), the outage performance does not improve with \( P_t \), but approaches the asymptotic bound (24), which verifies the accuracy of (24) in \textit{Theorem 5}. Moreover, the asymptotic bound (24) varies with...
N. Specifically, the asymptotic bound with $N = 4$ achieves the largest value, which coincides with the conclusion in Remark 2. Similar to Fig. 5, the accuracy of the derived expression in (22) is also verified by using simulations.

Fig. 8 shows the end-to-end outage probability versus the standard deviation $\sigma_{\text{angle},u}$ with different numbers of relays when $P_t = 20 \text{ dBm}$, $\theta_{\text{FoV},i} = 6 \text{ mrad}$, $w_u,i = 2 \text{ m}$, and $Z_{\text{SD}} = 2 \text{ km}$. As can be observed, with the increase of $\sigma_{\text{angle},u}$, the end-to-end outage probability increases sharply and then tends to one. This indicates that the system performance dramatically degrades with the increase of $\sigma_{\text{angle},u}$. Moreover, a large $\sigma_{\text{angle},u}$ (for example, $\geq 3.4 \text{ mrad}$) will directly result in a complete interruption of the system. Furthermore, when $\sigma_{\text{angle},u}$ is small, the outage probability performance improves with the number of UAV relays. Therefore, the UAVs’ orientation fluctuation and the number of relays are two major concerns for practical system design. In Fig. 8 all analytical results match well with simulation results, which also verifies the accuracy of the derived expression in (22).

C. Parameter Optimization Results

In this subsection, to verify the efficiency of the proposed optimization schemes, the parameter optimization results will be shown.

Fig. 9 shows the link outage probability of a UU link versus normalized FoV for different $P_t$ when $Z = 250 \text{ m}$ and $w_u = 2 \text{ m}$. As can be seen, with the increase of $P_t$, the link outage probability performance improves. Moreover, all analytical results accurately match simulation results in the entire normalized FoV range, which verifies the accuracy of (19) in Theorem 2. All curves tend to the asymptotic bound in (20) with the decrease of $\phi_{\text{FoV}}$, which indicates the correctness of Theorem 3. Furthermore, with the increase of $\phi_{\text{FoV}}$, the link outage probability decreases first and then increases. It can be observed from Fig. 9 that, when $P_t = 0, 5, 10, 15$ and $20 \text{ dBm}$, the optimal values of $\phi_{\text{FoV}}$ (in mrad) are 3.25, 4.25, 5.25, 6.08, and 6.92, respectively. By solving (30), we obtain the corresponding asymptotically optimal $\phi_{\text{FoV}}$ values as 1.94, 3.67, 4.98, 6.02, and 6.91. The differences between the optimal $\phi_{\text{FoV}}$ in Fig. 9 and the asymptotically optimal $\phi_{\text{FoV}}$ using (30) are small when $P_t$ is large. This indicates that, when $P_t$ is large, eq. (30) can be directly used to determine the optimal FoV without time-consuming simulations.

Fig. 10 shows the end-to-end outage probability versus FoV with different numbers of relays when $P_t = 20 \text{ dBm}$, $\sigma_{\text{angle},u} = 1.2 \text{ mrad}$, $\theta_{\text{FoV},i} = 6 \text{ mrad}$, $w_u,i = 4 \text{ m}$, and $Z_{\text{SD}} = 2 \text{ km}$. The obstacles are not considered, and the UAV relays are placed equidistant. The exhaustive search scheme and the asymptotically optimal scheme are provided. In the exhaustive search scheme, the FoVs for the GU, UG and UU links are set to be identical. In asymptotically
optimal scheme, the optimal FoVs for all links are respectively obtained by (30). It can be seen that when FoV is increased, all curves of the exhaustive search scheme decrease first and then increase, this indicates that an optimal FoV exists for each curve. Specifically, for $N = 1, 2, 3$ and 4, the optimal FoVs in the exhaustive search scheme are 4.7 mrad, 7.4 mrad, 9.2 mrad, and 10.8 mrad, as marked on the figure. The corresponding minimum outage probabilities are $8.95 \times 10^{-3}$, $4.26 \times 10^{-4}$, $5.40 \times 10^{-5}$, and $3.13 \times 10^{-8}$, respectively. Moreover, the FoVs of different links for the asymptotically optimal scheme by using (30) are also provided on the figure. As seen, the asymptotically optimal scheme can achieve comparable outage performance to the exhaustive search scheme, which verifies the accuracy of (30).

To verify whether the link with maximum distance (i.e., max-distance link) dominates the end-to-end outage performance, Fig. 11 shows the outage probability versus average transmit power $P_t$ for different scenarios when $Z_{SD} = 2$ km and $w_{z,i} = 4$ m. In this simulation, the beam width satisfies $\zeta_i^2 > \beta_i, i = 1, \ldots, N + 1$. Four cases are considered, as shown in Table I. Note that the asymptotic bounds for Cases 1 and 3 are $1.39 \times 10^{-11}$, the asymptotic bound for Case 4 is $2.78 \times 10^{-11}$, which are too small and not plotted in the figure. For cases with large FoV (i.e., Cases 1, 3 and 4) in Fig. 11, the outage probabilities of the max-distance link converge to that of the overall system when $P_t$ is large (for example, when $P_t \geq 12.5$ dBm for Case 1, when $P_t \geq 27.5$ dBm for Case 3, or when $P_t \geq 20$ dBm for Case 4), which verifies that the link with the maximum distance dominates the overall system performance, just as analyzed in (33). However, for the case with small FoV (i.e., Case 2), the outage probability of the max-distance link does not match with that of the overall system at large $P_t$. In this case, the AoA fluctuation has a strong effect on outage performance. Moreover, the performance of Case 2 is better than that of Case 1 before reaching the asymptotic bound (23) since larger FoV introduces more background noise.

After optimizing the UAVs’ locations, Fig. 12 and Fig. 13 show the deployment of UAVs under different scenarios. Specifically, Fig. 12 plots optimal relay deployment for the UAV-based FSO relaying system with one cylindrical obstacle. In the simulation, the coordinates of the source and the destination are (0.1 km, 0.1 km) and (2 km, 2 km). The obstacle is centered at (0.6 km, 1 km) with radius 0.5 km. From Fig. 12(a) to Fig. 12(d), the optimal locations of UAVs and link distances are listed in Table II. By adding another cylindrical obstacle at (1.6 km, 1.2 km) with radius 0.2 km, Fig. 13 shows the optimal relay deployment for the FSO relaying system. In this case, the optimal relay locations and link distances are provided in Table III. As can be seen from the above results, through optimizing the relays’ deployment, the feasible positions of relays can always be found, and all link distances tend to be approximately equal.

| Cases | Number of relays | Link distance (km) | FoV (mrad) |
|-------|------------------|--------------------|------------|
| Case 1 | 2                | $(Z_1, Z_2, Z_3) = (0.5, 0.5, 1)$ | 12         |
| Case 2 | 2                | $(Z_1, Z_2, Z_3) = (0.5, 0.5, 1)$ | 7          |
| Case 3 | 2                | $(Z_1, Z_2, Z_3) = (0.5, 0.7, 0.8)$ | 12         |
| Case 4 | 3                | $(Z_1, Z_2, Z_3, Z_4) = (0.4, 0.5, 0.5, 0.6)$ | 12         |

VI. CONCLUSIONS
This paper investigated the channel modelling, outage probability analysis, and parameter optimization for UAV-based FSO relaying systems. A tractable and accurate channel model was established by taking into account atmospheric loss, atmospheric turbulence, pointing error, and link interruption due to AoA fluctuation. Based on the channel model, closed-form expressions were obtained for link outage probability and end-to-end outage probability. Subsequently, the asymptotic outage performance bounds were also investigated. Moreover, the beam width, FoV and UAVs’ locations were optimized. Numerical results verify the accuracy of the derived theoretical expressions and the efficiency of the proposed optimization schemes. The obtained theoretical expressions enable designers to evaluate outage performance rapidly without time-intensive simulations. The derived parameter optimization results can help determine the optimal available parameter choices when designing the UAV-based FSO systems.

APPENDIX A
PROOF OF THEOREM 7
By using [4], [5], [10] and expressing $K_n(\cdot)$ in terms of the Meijer’s G-function [34], we can obtain the PDF of $h_i$ as [35]

\[
f_{h_i}(h_i) = \frac{\alpha_i \beta_i \zeta_i^2}{A_i h_i^{11/2} \Gamma(\alpha_i) \Gamma(\beta_i)} \times G_{1,3}^{3,0} \left[ \left\{ \frac{\alpha_i \beta_i}{A_i h_i^{11/2}} h_i^{\beta_i - 1} \right\} \zeta_i^2 \right]. \quad (A.1)
\]

By substituting (14) and (A.1) into (15), we derive the PDF of $h_i$ as

\[
f_{h_i}(h_i) = \exp \left( -\frac{\theta^2_{\text{FoV},i}}{2 m_i \sigma^2_{\text{angle},u}} \right) \int_0^\infty \frac{1}{h_i} \delta (\frac{h_i}{h_i'}) f_{h_i'}(h_i') \, dh_i' \nonumber \\
+ \left[ 1 - \exp \left( -\frac{\theta^2_{\text{FoV},i}}{2 m_i \sigma^2_{\text{angle},u}} \right) \right] \int_0^\infty \frac{1}{h_i} \delta (\frac{h_i}{h_i'}) f_{h_i'}(h_i') \, dh_i'. \quad (A.2)
\]

With $\delta(ax) = \delta(x)/|a|$ and $\int_0^\infty f(a) \delta(x-a) \, da = f(x)$ [36], eq. (16) can be derived.

APPENDIX B
PROOF OF THEOREM 2
By (16) and (17), $p_i$ is given by

\[
p_i = \exp \left( -\frac{\theta^2_{\text{FoV},i}}{2 m_i \sigma^2_{\text{angle},u}} \right) \int_0^{h_{th,i}} \delta(h_i) \, dh_i 
+ \left[ 1 - \exp \left( -\frac{\theta^2_{\text{FoV},i}}{2 m_i \sigma^2_{\text{angle},u}} \right) \right] \frac{\alpha_i \beta_i \zeta_i^2}{A_i h_i^{11/2} \Gamma(\alpha_i) \Gamma(\beta_i)} \times G_{1,3}^{3,0} \left[ \left\{ \frac{\alpha_i \beta_i}{A_i h_i^{11/2}} h_i^{\beta_i - 1} \right\} \zeta_i^2 \right]. \quad (B.1)
\]

Fig. 13. Optimal relay deployment for the UAV-based FSO relaying system with two cylindrical obstacles. (a) one relay, (b) two relays, (c) three relays, (d) four relays.
By (26) in [34], $I$ in (B.1) can be further written as

$$I = h_{t,h,i} G_{2,4}^{3,3} \left[ \frac{\alpha_i \beta_i}{A_i h_i(0)} \right] \left[ \begin{array}{c} 0, \zeta^2 \\ \zeta^2 - 1, \alpha_i - 1, \beta_i - 1, -1 \end{array} \right].$$

(B.2)

Then, by (9.31.5) in [27], eq. (B.2) can be written as

$$I = \frac{A_i h_i(0)}{\alpha_i \beta_i} G_{2,4}^{3,3} \left[ \frac{\alpha_i \beta_i}{A_i h_i(0)} \right] \left[ \begin{array}{c} 0, \zeta^2 \\ \zeta^2 - 1, \alpha_i - 1, \beta_i - 1, 0 \end{array} \right].$$

(B.3)

Submitting (B.3) and (18) into (B.1), we obtain (19).

PROOF OF Theorem 3

According to (18), when the transmit power $P_t$ tends to infinity, we have

$$\lim_{P_t \to \infty} h_{t,h,i} = \lim_{P_t \to \infty} \frac{\sqrt{\theta_{\text{FoS},i}^2 - \theta_{\text{angle},i}^2}}{2 R^2 P_t^2} = 0.$$  \hspace{1cm} (C.1)

In (19), the Meijer’s G-function cannot provide intuitive insights on the behavior of $h_{t,h,i}$. For a large transmit power $P_t$, the outage probability is dominated by the behavior of the PDF near the origin. Therefore, by employing (07.34.06.0006.01) in [37] or [36], we can approximate (19) as

$$p_i \approx \exp \left[ - \frac{\theta_{\text{FoV},i}}{2 \sigma_{\text{angle},i}} \right] + 1 - \exp \left[ - \frac{\theta_{\text{FoV},i}}{2 \sigma_{\text{angle},i}} \right] \times \frac{\zeta^2 \Gamma(\alpha_i - \kappa_i) \beta_i^\kappa_i (h_{t,h,i})^\kappa_i, \kappa_i = \min(\zeta^2, \beta_i),}$$

(C.2)

where $\kappa_i = 1/(\zeta^2 - \beta_i)$ if $\zeta^2 > \beta_i$, and $\kappa_i = \Gamma(\beta_i - \zeta^2)$ if $\zeta^2 < \beta_i$. Because the small-scale turbulence eddies parameter $\beta_i > 1$ [38], the inequality $\kappa_i > 1$ always holds.

By (C.1), the second term in (C.2) tends to zero when $P_t$ tends to infinity. Therefore, Theorem 3 holds.
