UNIVERSAL CENTRAL EXTENSIONS
OF INTERNAL CROSSED MODULES
VIA THE NON-ABELIAN TENSOR PRODUCT

DAVIDE DI MICCO AND TIM VAN DER LINDEN

Abstract. In the context of internal crossed modules over a fixed base object
in a given semi-abelian category, we use the non-abelian tensor product in
order to prove that an object is perfect (in an appropriate sense) if and only
if it admits a universal central extension. This extends results of Brown-
Loday (8, in the case of groups) and Edalatzadeh (14, in the case of Lie
algebras). Our aim is to explain how those results can be understood in terms
of categorical Galois theory: Edalatzadeh’s interpretation in terms of quasi-
pointed categories applies, but a more straightforward approach based on the
theory developed in a pointed setting by Casas and the second author 11
works as well.

1. Introduction

The aim of this article is to study a result on universal central extensions of
crossed modules due to Brown-Loday (8, in the case of groups) and Edalatzadeh
(14, in the case of Lie algebras). We prove, namely, that a crossed module over
a fixed base object is perfect (in an appropriate sense) if and only if it admits
a universal central extension. We first follow an ad-hoc approach, extending the
result to the context of Janelidze-Márki-Tholen semi-abelian categories 29 by using
a general version, developed in 13 of the non-abelian tensor product of Brown-
Loday 8. We then provide two interpretations from the perspective of categorical
Galois theory. The first one follows the line of Edalatzadeh 14 in the context of
quasi-pointed 3 categories (which have an initial object 0 and a terminal object 1
such that 0 → 1 is a monomorphism). This allows us to capture centrality, but
we could not find a natural way to treat perfectness in this setting. We then
switch to the pointed context (0 → 1) where the theory developed by Casas and the
second author 11 can be used. In this simpler environment we find a convenient
interpretation both of centrality and perfectness.

The text is structured as follows. In Section 2 we give an overview of basic
definitions and results of categorical Galois theory, with particular emphasis on
the example of so-called algebraically central extensions. In Section 3 we develop
a more advanced example: the coinvariants reflection from actions to trivial actions.
A key result here is Proposition 3.15 which says that for any object L a semi-
abelian category, the trivial L-actions form a Birkhoff subcategory of the category
of all L-actions.

In Section 4 we switch to the context of L-crossed modules. Here we recall
basic aspects, results from commutator theory, the non-abelian tensor product,
etc. In Section 5 we make an ad-hoc study of perfect objects and universal central

The second author is a Research Associate of the Fonds de la Recherche Scientifique–FNRS.
extensions in this context, especially in relation to the tensor product. We prove our first main result, Theorem 5.12, which says that in any semi-abelian category satisfying the so-called Smith is Huq condition (SH), an L-crossed module is perfect if and only if it admits a universal central extension.

The last two sections of the article are devoted to two Galois-theoretic points of view on this result. In Section 6 we consider a Galois theory in the quasi-pointed category $\text{XMod}_L(\mathcal{A})$ of L-crossed modules in $\mathcal{A}$, where we manage to give an interpretation of the central extensions (Theorem 6.8). In Section 7 we view an L-crossed module as an object of the semi-abelian category $\text{XMod}(\mathcal{A})$ and find a different Galois structure which characterises both the central extensions (Proposition 7.4) and the perfect objects (Proposition 7.6).

2. Revision of Galois Theory and Central Extensions

We recall some basic definitions and results of categorical Galois theory [2, 25, 27, 28], especially in relation with algebraic central extensions.

A regular epimorphism is a coequaliser of some pair of parallel arrows.

**Definition 2.1.** Let $\mathcal{C}$ be an exact category and $\mathcal{X}$ a subcategory of $\mathcal{C}$. We say that $\mathcal{X}$ is a Birkhoff subcategory of $\mathcal{C}$ if the following hold:

1. $\mathcal{X}$ is a full and reflective subcategory of $\mathcal{C}$,
2. $\mathcal{X}$ is closed under subobjects in $\mathcal{C}$ and
3. $\mathcal{X}$ is closed under (regular epimorphic) quotients in $\mathcal{C}$.

We usually denote the left adjoint as $I: \mathcal{C} \to \mathcal{X}$ and, when we do not omit it, the right adjoint as $H: \mathcal{X} \to \mathcal{C}$. The largest Birkhoff subcategory of $\mathcal{C}$ is obviously $\mathcal{C}$ itself, whereas the smallest one is given by $\text{Sub}(1)$ where 1 denotes the terminal object. When $\mathcal{C}$ is a variety, a Birkhoff subcategory is the same as a subvariety.

**Lemma 2.2** [27]. A reflective subcategory $\mathcal{X}$ of an exact category $\mathcal{C}$ is a Birkhoff subcategory iff for each regular epimorphism $f: A \to B$, the naturality square

\[
\begin{array}{ccc}
A & \xrightarrow{\eta_A} & HI(A) \\
\downarrow f & & \downarrow HI(f) \\
B & \xrightarrow{\eta_B} & HI(B)
\end{array}
\]

is a pushout of regular epimorphisms.

Recall that a commutative square is a regular pushout when all of its arrows, as well as the induced comparison to the pullback, are regular epimorphisms—see Figure 2.1. In general, pushouts and regular pushouts do not coincide; by Theorem 5.7 in [10] however, a regular category is an exact Mal’tsev category.
precisely when every pushout of two regular epimorphisms is a regular pushout. In particular, this is true in every semi-abelian category.

**Lemma 2.3.** [4] In a semi-abelian category, consider a square \( \beta \circ f = f' \circ \alpha \) of regular epimorphisms

\[
\begin{array}{ccc}
K_f & \xrightarrow{k_f} & A \\
\downarrow{k'} & & \downarrow{f} \\
K_{f'} & \xrightarrow{k_{f'}} & A' \\
\end{array}
\]

and take the kernels of \( f \) and \( f' \). The induced morphism \( k \) is a regular epimorphism if and only if the given square is a regular pushout. \( \square \)

2.4. **Central extensions.** In the exact Mal’tsev context, for each Birkhoff subcategory there is a Galois theory; we recall the main definitions having to do with central extensions.

**Definition 2.5.** We denote with \( \operatorname{Ext}_B(C) \) the category of extensions of \( B \) in \( C \), which is the full subcategory of \( C/B \) whose objects are the regular epimorphisms having \( B \) as codomain; notice that a morphism in \( \operatorname{Ext}_B(C) \) is any triangle in \( C \) from a regular epimorphism to another regular epimorphism with the same codomain \( B \).

**Definition 2.6.** Given a Birkhoff subcategory \( X \hookrightarrow C \) we say that an extension \( f : A \rightarrow B \) is an \( X \)-trivial extension (of \( B \)) when the naturality square \( \alpha \) is a pullback in \( C \). We will denote with \( \operatorname{Triv}_B(C,X) \) the full subcategory of \( \operatorname{Ext}_B(C) \) whose objects are the \( X \)-trivial extensions of \( B \).

**Definition 2.7.** Given a Birkhoff subcategory \( X \hookrightarrow C \) we say that an extension \( f : A \rightarrow B \) is an \( X \)-central extension (of \( B \)) when there exists an extension \( g : C \rightarrow B \) such that the pullback \( g^*(f) \)

\[
\begin{array}{ccc}
A \times_B C & \xrightarrow{g^*(f)} & C \\
\downarrow{g} & & \downarrow{g} \\
A & \xrightarrow{f} & B \\
\end{array}
\]

of \( f \) along \( g \) is an \( X \)-trivial extension. We will denote by \( \operatorname{Centr}_B(C,X) \) the full subcategory of \( \operatorname{Ext}_B(C) \) whose objects are the \( X \)-central extensions of \( B \). We have the chain of inclusions

\[ \operatorname{Triv}_B(C,X) \subseteq \operatorname{Centr}_B(C,X) \subseteq \operatorname{Ext}_B(C). \]

**Lemma 2.8.** In the context of an exact protomodular category \( C \), an extension \( f : A \rightarrow B \) is \( X \)-central if and only if one of the projections \( r_0, r_1 \) in the kernel pair

\[
\begin{array}{ccc}
Eq(f) & \xrightarrow{r_0} & A \\
\downarrow{r_1} & & \downarrow{f} \\
A & \xrightarrow{f} & B \\
\end{array}
\]

is a \( X \)-trivial extension. Furthermore, a split epimorphism is an \( X \)-central extension if and only if it is \( X \)-trivial.

**Proof.** Proposition 4.7 in [27] tells us that the two claims are equivalent while Theorem 4.8 proves that they hold in every Goursat category. Protomodularity implies the Mal’tsev property, which is stronger than the Goursat property. \( \square \)
2.9. Example: algebraically and categorically central extensions. A key example of a Birkhoff subcategory is the subcategory \( \text{Ab}(\mathcal{A}) \) of abelian objects in any semi-abelian category \( \mathcal{A} \), which are those objects that admit an internal abelian group structure. For instance, abelian groups in the category of all groups, or vector spaces equipped with a trivial (zero) multiplication in any category of Lie algebras over a field. It is clear that \( \text{Ab}(\mathcal{A}) \) is an abelian category, but it is also a Birkhoff subcategory of \( \mathcal{A} \): indeed it is a full reflective subcategory of \( \mathcal{A} \), closed under subobjects and regular quotients.

This means that we have a definition of \( \text{Ab}(\mathcal{A}) \)-central extensions, also called categorically central extensions in contrast with algebraically central extensions; the former are given through Definition 2.7, whereas the latter ones arise naturally in the Higgins commutator theory. As it turns out, the two types of central extensions coincide if we consider the kernel pair of a representing monomorphism \( \text{cl}_X(K, L) \) of abelian objects \( \mathcal{A} \) in any semi-abelian category \( \mathcal{A} \), a priori, the kernel of the cokernel of a representing monomorphism \( K \rightarrow X \)—may be obtained as the join \( K \vee [K, X] \), and \( [K, X] \) is normal if and only if it admits a universal abelian object \( X \) in \( \mathcal{A} \).

Algebraic centrality of an extension \( f: A \rightarrow B \) is now the condition that \( [K, A] \) is trivial, for \( K \) the kernel of \( f \). Equivalently, by \cite{22} combined with \cite{20, 28}, this may be expressed in terms of the kernel pair of \( f \). The main result of \cite{5} says that algebraically and categorically central extensions coincide. This implies right away that in the cases of groups and Lie algebras, we regain the classical definitions.

2.10. Universal central extensions. The following definitions are borrowed from the article \cite{11}, where the theory of universal central extensions is explored in detail. We consider a Birkhoff subcategory \( \mathcal{X} \rightarrow \mathcal{C} \) of a pointed exact Mal’tsev category.

Definition 2.11. We say that an extension \( u: U \rightarrow B \) is a universal \( \mathcal{X} \)-central extension of \( B \) if it is an initial object in \( \text{Centr}_B(\mathcal{C}, \mathcal{X}) \).

Definition 2.12. We say that an object \( A \in \mathcal{C} \) is \( \mathcal{X} \)-perfect whenever its reflection \( I(A) \) is the zero object \( 0 \in \mathcal{X} \).

Via the analysis in \cite{29} these definitions capture the usual ones for groups and Lie algebras. A key result in this general context is \cite{11} Theorem 3.5, which says that an object in a semi-abelian category \( \mathcal{A} \) is perfect with respect to a Birkhoff subcategory \( \mathcal{X} \rightarrow \mathcal{A} \) if and only if it admits a universal \( \mathcal{X} \)-central extension.

2.13. More on trivial extensions. Given a Birkhoff subcategory \( \mathcal{X} \rightarrow \mathcal{C} \) of an exact Mal’tsev category \( \mathcal{C} \), it is well known and easy to see that the category \( \text{Triv}_B(\mathcal{C}, \mathcal{X}) \) is again reflective in \( \text{Ext}_B(\mathcal{C}) \): reflect the given extension into \( \mathcal{X} \), then...
pull back along the unit. In the setting of a semi-abelian category \( \mathcal{A} \) with its Birkhoff subcategory of abelian objects \( \text{Ab}(\mathcal{A}) \), we may restrict the left adjoint to the split epimorphisms in \( \mathcal{A} \), and find the following. Let \( f: A \to B \) be a split epimorphism, with splitting \( s \) and kernel \( k: K \to A \); then the unit of the adjunction at \( f \) gives rise to the morphism of split short exact sequences

\[
0 \to K \xrightarrow{k} A \xrightarrow{s} B \to 0
\]

Note, in particular, that the object \( K/\{K,A\} \) is abelian.

3. Actions, trivial actions, coinvariants

In this section we work out a less trivial example of a Galois structure, which later on will be useful for us: we study the so-called coinvariants reflector from internal actions to trivial actions. This is a categorical conceptualisation of a classical construction, well known in group cohomology: see [7], for instance. It generalises the result of 2.13 to split extensions with a non-abelian kernel.

We start by recalling some well-known basic results on limits and colimits, easily checked by hand, in the category of points over a fixed base object. Throughout, we let \( L \) be a fixed object in a semi-abelian category \( \mathcal{A} \).

3.1. Points, actions, split extensions. A point \((p, s)\) in a category \( \mathcal{A} \) is a split epimorphism \( p: X \to L \) together with a chosen splitting \( s: L \to X \), so that \( p \circ s = 1_L \). The category \( \text{Pt}(\mathcal{A}) \) of points in \( \mathcal{A} \) has, as objects, points in \( \mathcal{A} \), and as morphisms, natural transformations between such. If \( \mathcal{A} \) is a semi-abelian category, then a point \((p, s)\) with a chosen kernel \( k \) of \( p \) is the same thing as a split extension in \( \mathcal{A} \): a split short exact sequence

\[
0 \to K \xrightarrow{k} X \xrightarrow{p} L \to 0,
\]

which means that \( k \) is the kernel of \( p \), that \( p \) is the cokernel of \( k \), and that \( p \circ s = 1_L \). In such a split extension, \( k \) and \( s \) are jointly extremal-epimorphic. Via a semi-direct product construction [6], we have an equivalence \( \text{Pt}(\mathcal{A}) \cong \text{Act}(\mathcal{A}) \), where the latter category of internal actions in \( \mathcal{A} \) consists of the algebras of the monad \((Lb(-), \eta^L, \mu^L)\) defined through

\[
0 \to LbM \xrightarrow{k_{L,M}} L + M \xrightarrow{\begin{pmatrix} 1_L \\ \eta^L \\ \mu^L \end{pmatrix}} L \xrightarrow{1_L} 0.
\]

One functor in the equivalence sends a point \((p, s)\) to the action \((L,K,\xi)\) in

\[
0 \to LbK \xrightarrow{k_{L,K}} L + K \xrightarrow{\begin{pmatrix} 1_L \\ \eta^L \end{pmatrix}} L \xrightarrow{1_L} 0
\]

\[
0 \to K \xrightarrow{k} X \xrightarrow{p} L \to 0.
\]
Figure 3.1. Kernels in $\mathbf{Pt}_L(\mathbb{A})$.

The other functor sends an action $(L, M, \xi)$ to the induced semidirect product, which is the point $(\pi_\xi: M \rtimes \xi L \to L, i_\xi: L \to M \rtimes \xi L)$, where $M \rtimes \xi L$ is the co-equaliser

$$L \rtimes M \xrightarrow{k_{L,M}} L + M \xrightarrow{\sigma_\xi} M \rtimes \xi L,$$

the morphism $\pi_\xi: M \rtimes \xi L \to L$ is the unique morphism such that $(1_L) = \pi_\xi \circ \sigma_\xi$, and finally $i_\xi = \sigma_\xi \circ i_M$. We will denote $M \rtimes \xi L$ as $M \rtimes \xi$ if there is no risk of confusion regarding the action involved. The morphism $k_\xi := \sigma_\xi \circ i_M: M \to M \rtimes \xi L$ is always the kernel of $\pi_\xi$: it is easy to see that $\pi_\xi \circ k_\xi = 0$, whereas for the universal property some work needs to be done. In particular, if we fix the object $L$, we obtain the subcategories $\mathbf{Pt}_L(\mathbb{A})$ and $\mathbf{Act}_L(\mathbb{A})$, as well as the restricted equivalence $\mathbf{Pt}_L(\mathbb{A}) \simeq \mathbf{Act}_L(\mathbb{A})$.

Lemma 3.2. A morphism in the category $\mathbf{Pt}_L(\mathbb{A})$ is a regular epimorphism if and only if the morphism between the domains is a regular epimorphism in $\mathbb{A}$. □

Lemma 3.3. A square in the category $\mathbf{Pt}_L(\mathbb{A})$ is a pushout (a pullback) if and only if the square between the domains is a pushout (a pullback) in $\mathbb{A}$. This means that pushouts and pullbacks can be computed in the base category using just the domains: the additional structure is canonically induced. □

As a consequence we have a simple way to compute kernels in $\mathbf{Pt}_L(\mathbb{A})$.

Corollary 3.4. Consider a morphism of $L$-points as in Figure 3.1 on the left. Then its kernel is the $L$-point induced by the outer pullback on the right. □

3.5. The join decomposition formula. In what follows, we need to be able to decompose a commutator of a join of subobjects into a join of commutators. This goes by means of a join decomposition formula which involves a ternary version of the Higgins commutator:

Definition 3.6 ([9][23][22]). Given objects $A, B$ and $C$ in $\mathbb{A}$, consider the morphism

$$\Sigma_{A,B,C} = \begin{pmatrix} i_A & i_A & 0 \\ i_B & 0 & i_B \\ 0 & i_C & i_C \end{pmatrix}: A + B + C \longrightarrow (A + B) \times (A + C) \times (B + C)$$

and its kernel $h_{A,B,C}: A \circ B \circ C \to A + B + C$. The object $A \circ B \circ C$ is called the cosmash product of $A, B$ and $C$. 

Given three subobjects \((K, k), (M, m)\) and \((N, n)\) of an object \(X\), we define their \textit{Higgins commutator} as the subobject of \(X\) given by the factorisation
\[
K \circ M \circ N \xrightarrow{h_{K, M, N}} K + M + N
\]
\[
\xrightarrow{(k/m)} [K, M, N] \xrightarrow{e} X.
\]
We call \([K, M, N]\) the \textit{ternary Higgins commutator} of \(K, M\) and \(N\) in \(X\).

**Proposition 3.7** \([23][22]\). Suppose \(K_1, K_2, K_3 \subseteq X\). Then we have the following (in)equalities of subobjects of \(X\):

1. if \(K_1 = 0\) then \([K_1, K_2] = 0 = [K_1, K_2, K_3];
2. \([K_1, K_2] = [K_2, K_1]\) and for \(\sigma \in S_3\), \([K_1, K_2, K_3] = [K_{\sigma(1)}, K_{\sigma(2)}, K_{\sigma(3)}];
3. for any regular epimorphism \(f: X \rightarrow Y\), \([f[K_1, K_2]] \subseteq [f(K_1), f(K_2)] \subseteq Y;
4. \([L_1, K_2, K_3] \subseteq [K_1, K_2, K_3];
5. \([K_1, K_2, K_3] \subseteq [K_1, K_2, K_3];
6. \([K_1, K_2, K_3] = [K_1, K_2] \cup [K_1, K_3] \cup [K_1, K_2, K_3].

As we shall see, item (6) allows us to reduce commutators to simpler ones.

### 3.8. Trivial actions

We now define a suitable Birkhoff subcategory of \(\text{Act}_L(\hat{\mathcal{A}})\): the subcategory \(\text{TrivAct}_L(\hat{\mathcal{A}})\) of trivial \(L\)-actions.

**Definition 3.9.** Consider an \(L\)-action expressed as a point with a chosen kernel
\[
0 \rightarrow M \xrightarrow{k_p} X \xrightarrow{p} L \rightarrow 0.
\]
We say that it is a \textit{trivial action} when there exists an isomorphism of split short exact sequences
\[
0 \rightarrow M \xrightarrow{k_p} X \xrightarrow{p} L \rightarrow 0 \\
0 \xrightarrow{(1_M, 0)} M \times L \xrightarrow{(\pi_2, 0)} L \rightarrow 0.
\]
The category \(\text{TrivAct}_L(\hat{\mathcal{A}})\) of trivial \(L\)-actions is the full subcategory of \(\text{Act}_L(\hat{\mathcal{A}})\) whose objects are trivial \(L\)-actions.

**Construction 3.10.** We wish to construct a functor \(I: \text{Act}_L(\hat{\mathcal{A}}) \rightarrow \text{TrivAct}_L(\hat{\mathcal{A}})\), left adjoint to the inclusion functor \(H: \text{TrivAct}_L(\hat{\mathcal{A}}) \rightarrow \text{Act}_L(\hat{\mathcal{A}})\). Given a split extension as in the top row of the diagram
\[
0 \rightarrow M \xrightarrow{k_p} X \xrightarrow{p} L \rightarrow 0 \\
0 \xrightarrow{(1_M, 0)} C_s \times L \xrightarrow{(\pi_2, 0)} L \rightarrow 0,
\]
we take the cokernel \(C_s\) of the splitting \(s\), which leads to the bottom split extension and the morphism between them. The trivial \(L\)-action corresponding to the bottom sequence is called the \textit{object of coinvariants} of the given action, and it is the image through \(I\) of the action we began with. The morphism of split extensions corresponds to the unit \(\eta: 1_{\text{Act}_L(\hat{\mathcal{A}})} \Rightarrow HI\) of the adjunction at \((p, s)\).
We still need to prove that the thus constructed functor \( I \) is a Birkhoff reflector, of course. The following definition follows the pattern of \([16, 18]\): the kernel of the unit of a Birkhoff reflector is viewed as a commutator, relative to this reflector.

**Definition 3.11.** With the notation of the previous construction, in Figure 3.2 we take the kernel of the unit \( \eta \) as in Corollary 3.4. It is easily seen that this square is indeed a pullback. Recall that \( \text{cl}_X(L) \) is the normal closure of \( L \leq X \) in \( X \), which may be obtained as the kernel of \( c_s \). Taking kernels of the split epimorphisms, we get horizontal short exact sequences as in

\[
0 \rightarrow [L, M] \overset{k_{(c_s \circ \pi)}}{\longrightarrow} cl_X(L) \overset{k_s}{\longrightarrow} L \overset{0}{\longrightarrow} \\
0 \rightarrow M \overset{k_p}{\longrightarrow} X \overset{p}{\longrightarrow} L \overset{0}{\longrightarrow} \\
0 \rightarrow C_s \overset{\langle c_s, 0 \rangle}{\longrightarrow} C_s \times L \overset{\pi_2}{\longrightarrow} L \overset{0}{\longrightarrow}
\]

and we define the *coinvariants commutator* \([L, M]\) as the top left kernel.

**Remark 3.12.** By construction we have the diagram

\[
0 \rightarrow M \overset{k_p}{\longrightarrow} X \overset{p}{\longrightarrow} L \overset{0}{\longrightarrow} \\
0 \rightarrow C_s \overset{\langle c_s, 0 \rangle}{\longrightarrow} C_s \times L \overset{\pi_2}{\longrightarrow} L \overset{0}{\longrightarrow} \\
0 \rightarrow C_s \overset{\langle 1_{C_s}, 0 \rangle}{\longrightarrow} C_s \times L \overset{\pi_1}{\longrightarrow} L \overset{0}{\longrightarrow}
\]

where the vertical composite rectangle

\[
\begin{array}{ccc}
X & \overset{p}{\longrightarrow} & L \\
\downarrow_{c_i} & & \downarrow_0 \\
C_s & \overset{0}{\longrightarrow} & 0
\end{array}
\]

is a pushout of regular epimorphisms, hence a regular pushout. Indeed the universal property can be shown directly by using the fact that \( p \circ s = 1_L \) and that \( c_s \) is the cokernel of \( s \). Since \( \langle c_s, p \rangle \) is the comparison morphism to the induced pullback, it is automatically a regular epimorphism. By Lemma 3.2 this is equivalent to \( \eta_{(p, s)} \).
being a regular epimorphism of points over \( L \). Furthermore, since the top left square is a pullback, also \( c_s \circ k_p \) is a regular epimorphism.

**Remark 3.13.** Since kernels commute with kernels, we can obtain \([L, M]\) as the kernel of \( c_s \circ k_p \), computed in \( \mathcal{A} \). Since the lower left square in the diagram of Definition 3.11 is a pullback, the composite \( k_p \circ k(c_s \circ k_p) \) is the kernel of \( \langle c_s, p \rangle \), so that \([L, M] \leq X\). On the other hand, since the upper left square is a pullback as well, we have that \([L, M] = M \wedge cl_X(L)\).

An alternative argument goes as follows. \( M \) is the kernel of \( p \), while the kernel of \( c_s \) is precisely the normal closure of \( L \) in \( X \); the kernel of \( \langle c_s, p \rangle \) is the intersection of those two kernels.

By the discussion in 2.9, we know that \( cl_X(L) = L \vee [L, X] \) in \( X \). On the other hand, the top split extension in the diagram of Definition 3.11 tells us that \( cl_X(L) = L \vee [L, M] \). The following simplifies this, by relating the two types of commutator.

**Proposition 3.14.** Given a split extension over \( L \)

\[
0 \longrightarrow M \xrightarrow{k} X \xrightarrow{p} L \longrightarrow 0,
\]

its coinvariance commutator \([L, M]\), seen as a subobject of \( X \), coincides with the Higgins commutator \([L, M]\) of \( L \) and \( M \) in \( X \). In particular, \( C_s \cong M/[L, M] \).

**Proof.** Consider the morphism of split extensions

\[
0 \longrightarrow L \circ M \xrightarrow{i_{L, M}} LbM \xleftarrow{\iota} L \longrightarrow 0 \quad \text{(B)}
\]

Its image is the point \( L \vee [L, M] \rightrightarrows L \), whose kernel is \([L, M]\).

Both \( cl_X(L) \rightrightarrows L \) and \( L \vee [L, M] \rightrightarrows L \) are normal subobjects of \( X \rightrightarrows L \). (For the latter, this follows because \( k \) is a regular epimorphism and \( k_{L, M} \circ i_{L, M} \) is a normal monomorphism in \( \mathcal{A} \), so that the image \([L, M]\) of their composite is normal in \( X \).) Hence if we show that one vanishes if and only if the other does—so that they express the same universal property, namely the condition that \( \text{(B)} \) represents a trivial action—then they coincide. For the point \( cl_X(L) \rightrightarrows L \) we already know that its kernel is \([L, M]\), which is zero if and only if \( \text{(B)} \) is trivial.

First suppose that \( \text{(B)} \) represents a trivial action, so that \([L, M] = 0\). Then \( M \) and \( cl_X(L) \) are two normal subobjects of \( X \) with a zero intersection, which implies that \([cl_X(L), M] \subseteq cl_X(L) \wedge M \) is trivial. Hence \([L, M] \subseteq [cl_X(L), M] = 0\).

Conversely, if \([L, M] = 0\), then by Proposition 3.7

\[
[L, X] = [L, M] \vee [L, L] \vee [L, L, M] \subseteq [L, M] \vee [L, L] = [L, L] \subseteq L
\]

so that \( cl_X(L) = L \) and \([L, M] \) vanishes. \( \square \)

**Proposition 3.15.** \( \text{TrivAct}_L(\mathcal{A}) \) is a Birkhoff subcategory of \( \text{Act}_L(\mathcal{A}) \).

**Proof.** By its construction and by Remark 3.12 the regular epimorphic natural transformation \( \eta: 1_{\text{Act}_L(\mathcal{A})} \Rightarrow HI \) is the cokernel of a normal subfunctor \( V \) of \( 1_{\text{Act}_L(\mathcal{A})} \) which sends a split extension as in \( \text{(B)} \) to the split extension determined by the point \( cl_X(L) \rightrightarrows L \). By Corollary 5.7 in [16], this shows that \( I \) is a Birkhoff reflector if and only if the functor \( V \) preserves regular epimorphisms. Hence it
suffices to prove that each regular epimorphism of points over $L$
\[
\begin{array}{ccc}
M & \xrightarrow{p} & L \\
\downarrow f & & \downarrow \\
M' & \xrightarrow{p'} & L
\end{array}
\]
is sent to a regular epimorphism of points by the functor $V$. By Proposition 3.14, this holds because the induced morphism $[1_L, f] : [L, M] \to [L, M']$ is again a regular epimorphism; this follows from Lemma 5.11 in [30]. □

Remark 3.16. According to Definition 2.12 we have that an $L$-action corresponding to 3.12 is $\text{TrivAct}_L(\mathcal{A})$-perfect if and only if its image through $I$ is the zero $L$-action $(0 : 0 \to L, \tau_L)$ which corresponds to the split extension

\[
\begin{array}{cccc}
0 & \xrightarrow{p} & L & \xrightarrow{\iota_L} L & \xrightarrow{\iota_L} 0.
\end{array}
\]

This, in turn, is equivalent to the equality of subobjects $[L, M] = [L, M] = M$. Hence an $L$-action on an object $M$ is perfect iff $M \triangleleft \text{cl}_X(L)$, which is equivalent to saying that the normal closure $\text{cl}_X(L)$ of $L$ in $X$ is all of $X$.

4. Internal crossed modules

We now focus on internal crossed modules in semi-abelian categories. Internal crossed modules are equivalent to internal categories; the conditions that make this happen were obtained in [26]. In order to have a description which is as simple as possible, we require that $\mathcal{A}$ satisfies an additional condition, called the Smith is Huq condition (SH). A semi-abelian category satisfies it when the Smith/Pedicchio commutator [33] of two internal equivalence relations vanishes if and only if so does the Huq commutator of their associated normal subobjects [1, 31]. As explained in [23], in terms of Higgins commutators, this amounts to the condition that whenever $M, N \triangleleft L$ are normal subobjects, $[M, N] = 0$ implies $[M, N, L] = 0$.

Examples of semi-abelian categories that satisfy (SH) include the categories of groups, (commutative) rings (not necessarily unitary), Lie algebras over a commutative ring with unit, Poisson algebras and associative algebras, as are all varieties of such algebras, and crossed modules over these. In fact, all Orzech categories of interest [32, 12] are examples. On the other hand, the category of loops is semi-abelian but does not satisfy (SH). Further details can be found in [26, 23, 31].

The work of Janelidze [26] provides an explicit description of internal crossed modules in terms of internal actions, together with an equivalence of categories $\text{XMod}(\mathcal{A}) \simeq \text{Grpd}(\mathcal{A})$ which extends the equivalence $\text{Act}(\mathcal{A}) \simeq \text{Pt}(\mathcal{A})$. Since the category of internal groupoids in a semi-abelian category is again semi-abelian [31], the category of internal crossed modules is semi-abelian as well. It is explained in [23] that under (SH), Higgins commutators suffice for the description of internal groupoids. Furthermore, the characterisation of internal crossed modules given in [26] simplifies—see below. This is our main reason for working in this context.

Definition 4.1. In a semi-abelian category $\mathcal{A}$ with (SH), an internal crossed module is a pair $(\cdot : M \to L, \xi)$ where $\cdot : M \to L$ is a morphism in $\mathcal{A}$ and $\xi : L \triangleright M \to M$ is
an internal action such that the diagram

\[
\begin{array}{c}
M \cong M \xrightarrow{\varepsilon M} LbM \\
\downarrow & & \downarrow \\
M & \xrightarrow{\chi M} & LbL
\end{array}
\]

commutes. \((\ast_1)\) is the Peiffer condition, and \((\ast_2)\) the precrossed module condition.

In this general context we have been able to define, for each pair of coterminal internal crossed modules \((\mu: M \to L, \xi_M)\) and \((\nu: N \to L, \xi_N)\), a generalisation of the Brown-Loday non-abelian tensor product: see Figure 4.1. In particular, our construction uses the universal property of the non-abelian tensor product described in [8], through the equivalence \(\text{Grpd}(\mathcal{A}) \cong \text{XMod}(\mathcal{A})\) between the categories of internal groupoids and internal crossed modules. For further details see [13] and the proof of Proposition 5.8.

Lemma 4.2. Consider a morphism of internal crossed modules

\[
(\varepsilon: M \to L, \xi) \xrightarrow{(f, l)} (\varepsilon': M' \to L', \xi').
\]

Then \((f, l)\) is a regular epimorphism in \(\text{XMod}(\mathcal{A})\) if and only if \(f\) and \(l\) are regular epimorphisms in \(\mathcal{A}\).

Proof. In the category \(\text{RG}(\mathcal{A})\) of reflexive graphs in \(\mathcal{A}\), coequalisers are computed pointwise, and due to Theorem 3.1 and Lemma 3.1 in [19] this implies that also in \(\text{Grpd}(\mathcal{A})\) the coequalisers are computed pointwise. This means that a morphism

\[
(X, L, d, c, e, m) \xrightarrow{(x, l)} (X', L', d', c', e', m')
\]

is the coequaliser of \((g_0, g_1)\) and \((h_0, h_1)\) in \(\text{Grpd}(\mathcal{A})\) if and only if \(l\) is the coequaliser \(c_{g_1, h_1}\) and if \(x\) is the coequaliser \(c_{g_0, h_0}\). Using the equivalence of categories \(\text{XMod}(\mathcal{A}) \cong \text{Grpd}(\mathcal{A})\) and the diagram

\[
\begin{array}{c}
M \xrightarrow{k_d} X \xrightarrow{d} L \\
\downarrow f & & \downarrow l \\
M' \xrightarrow{k_{d'}} X' \xrightarrow{d'} L'
\end{array}
\]
where $X = M \rtimes_L X'$, $X' = M' \rtimes_{L'} L$ and $x = f \rtimes l$, we conclude that $(f, l)$ is a regular epimorphism in $\mathbf{XMod}(\mathcal{A})$ iff both $l$ and $x$ are regular epimorphisms in $\mathcal{A}$. Now it suffices to apply the “Short Five Lemma for regular epimorphisms”—item 5 in [1, Lemma 4.2.5]—to finish the proof. □

**Lemma 4.3.** For any internal crossed module $(\partial: M \twoheadrightarrow L, \xi)$, the object $M/[L, M]$ is abelian.

*Proof.* The Peiffer condition yields a commutative diagram

\[
\begin{array}{c}
M \circ M \xrightarrow{\partial \circ 1_M} M \circ M \xrightarrow{\chi} M \\
L \circ M \xrightarrow{\partial \circ 1_M} L \circ M \xrightarrow{\xi} M.
\end{array}
\]

It is clear that the image of the top composition is $[M, M]$, while the image of $\xi \circ \partial_{L, M}$ is $[L, M]$ because this commutator is the image of $k_L \xi \circ \partial_{L, M} = \left(\xi \circ \partial_{L, M}\right)_{k_L}$ : $L \circ M \rightarrow M \rtimes_L L$ in $M \leq M \rtimes_L L$. Taking cokernels horizontally, we obtain a regular epimorphism $M/[M, M] \twoheadrightarrow M/[L, M]$. Hence $M/[L, M]$ is abelian, as a quotient of an abelian object. □

**Remark 4.4.** This means that for the action $\xi$ of a crossed module $(\partial: M \twoheadrightarrow L, \xi)$, there is no difference between the procedure of 2.13 and the construction described in 3.10.

**4.5. Crossed modules over a fixed object.** Let $L$ be an object of $\mathcal{A}$. A *crossed module over $L$* or $L$-*crossed module* is a crossed module $(\partial: M \twoheadrightarrow L, \xi)$ in $\mathcal{A}$ where the codomain of $\partial$ is the given object $L$. Together with morphisms of crossed modules that keep the object $L$ fixed, this defines the category $\mathbf{XMod}_L(\mathcal{A})$.

A key issue here is, that $\mathbf{XMod}_L(\mathcal{A})$ is not a semi-abelian category: indeed, it is not pointed, since the initial $L$-crossed module is $(0: 0 \rightarrow L, \tau^L_0)$, while the terminal $L$-crossed module is $(1_L: L \rightarrow L, \tau^L_1)$. On the other hand, it is still *quasi-pointed* (in the sense of [3]), which means that $0 \rightarrow 1$ is a monomorphism), regular and protomodular, which makes it a so-called *sequentiable* category. Furthermore, it is Barr-exact, so it is actually not far from being semi-abelian.

**Remark 4.6.** Consider a morphism of $L$-crossed modules

\[
(M \xrightarrow{\partial} L, \xi) \xrightarrow{(f, 1_L)} (M' \xrightarrow{\partial'} L, \xi').
\]

The kernel of this morphism is given by

\[
(K_f: 0 \rightarrow L, \xi) \xrightarrow{(k_f, 1_L)} (M \xrightarrow{\partial} L, \xi),
\]

where the action $\xi$ is induced by the universal property of $K_f$ as shown in

\[
\begin{array}{c}
L \circ K_f \xrightarrow{1_{L} \circ k_f} L \circ M \xrightarrow{1_{L} \circ f} L \circ M' \\
\xi \downarrow \quad \downarrow \xi' \\
K_f \circ M \xrightarrow{k_f} M \rightarrow M'.
\end{array}
\]

It is easy to see that this is an $L$-crossed module.
Lemma 4.7. Consider a morphism of $L$-crossed modules

$$(M \xrightarrow{\xi} L, \xi) \xrightarrow{(f,1_L)} (M' \xrightarrow{\xi'} L, \xi').$$

Then $(f,1_L)$ is a monomorphism in $\text{XMod}_L(\mathbb{A})$ iff $f$ is mono in $\mathbb{A}$. □

5. Central extensions of crossed modules, ad-hoc approach

We let $\mathbb{A}$ be a semi-abelian category that satisfies (SH). Copying what happens for groups and Lie algebras, we make the following definitions. By 2.9 we know about first one, of course; later on we shall also justify the latter two from a Galois theory perspective.

Definition 5.1. A central extension in $\mathbb{A}$ (with respect to $\text{Ab}(\mathbb{A})$) is a regular epimorphism $f: X \twoheadrightarrow Y$ with kernel $K$ such that $[K,X] = 0$.

Example 5.2. If $(\hat{\xi}: M \rightarrow L, \xi)$ is a crossed module, then the regular epimorphism in the image factorisation of $\hat{\xi}$ is a central extension; in other words, $[L,K] = 0$.

Definition 5.3. Let $L$ be an object of $\mathbb{A}$. A central extension in $\text{XMod}_L(\mathbb{A})$ is a regular epimorphism of $L$-crossed modules

$$(M \xrightarrow{\xi} L, \xi) \xrightarrow{(f,1_L)} (M' \xrightarrow{\xi'} L, \xi')$$

where for the kernel $K$ of $f$ we have that $[L,K] = 0$.

Remark 5.4. Notice that this means that the kernel $0: K \rightarrow L$ of $(f,1_L)$ has a trivial $L$-action.

Definition 5.5. Let $L$ be an object of $\mathbb{A}$. A perfect object in $\text{XMod}_L(\mathbb{A})$ is an $L$-crossed module $(\hat{\xi}: M \rightarrow L, \xi)$ such that $[L,M] = M$.

Lemma 5.6. An $L$-crossed module $(\hat{\xi}: M \rightarrow L, \xi)$ is perfect if and only if in the corresponding internal groupoid

$$M \times L \xrightarrow{d} L$$

the normal closure $\text{cl}_{M \times L}(L)$ of $c$ is all of $M \rtimes L$.

Proof. This follows immediately from the explanation in Remark 3.16. □

Lemma 5.7 (Proposition 3.9 in [17]). For a reflexive graph with its normalisation

$$K_d \xrightarrow{k_d} C_1 \xrightarrow{c} C_0,$$

the coequaliser $C_{(d,c)}$ of $d$ and $c$ is isomorphic to the cokernel $C_{c \circ k_d}$ of $c \circ k_d$. □

Proposition 5.8. Given a crossed module $(\hat{\xi}: M \rightarrow L, \xi)$ we can construct the crossed square

$$\begin{array}{ccc}
L \otimes M & \xrightarrow{\delta_M} & M \\
\downarrow & & \downarrow \beta \\
L & \xrightarrow{\beta} & L
\end{array}$$

by taking the non-abelian tensor product $[13]$. Then $\delta_M$ is a regular epimorphism iff $(\hat{\xi}: M \rightarrow L, \xi)$ is perfect.
Proof. Let us recall the construction of the non-abelian tensor product in this special situation. First of all we denormalise both $(\hat{c} : M \to L, \xi)$ and $(1_L : L \to L, \chi_L)$ and we take the pushout of the two split monomorphisms $e$ and $\Delta_L$ to obtain the square of reflexive graphs

Then we take a certain quotient of $P$ that universally turns the diagram into a double groupoid as in Figure 5.1. Finally we normalise the entire double groupoid to obtain Figure 5.2. Now we are ready to prove the result. First of all, by applying the “Short Five Lemma for regular epimorphisms” [1, Lemma 4.2.5.5] to the diagram
we deduce that $\delta_M$ is a regular epimorphism iff $\delta_M \times 1_L$ is so. Then using

we see that $\delta_M \times 1_L$ is a regular epimorphism iff $\delta_P$ is so.

Since $\delta_P$ is a proper morphism (as a composite of a regular epimorphism with a normal monomorphism in a semi-abelian category), it is a regular epimorphism iff it has a trivial cokernel.

On the other hand, Lemma 5.7 says that for every reflexive graph, the cokernel of the normalisation is the same as the coequaliser of the two split epimorphisms: this implies that the first one is trivial iff the second one is so. Let us draw a picture involving the desired coequaliser $Q$.

Here the second row involves the coequaliser of $\pi_1$ and $\pi_2$.

Let us prove by hand that $q$ is the cokernel of $e$. Consider $\gamma: M \times L \to Z$ such that $\gamma \circ e = 0$: since $q$ is the coequaliser of $p_1$ and $p_2$, in order to have a unique morphism $\phi: Q \to Z$ such that $\phi \circ q = \gamma$ it suffices that $\gamma \circ p_1 = \gamma \circ p_2$. We use the fact that $P$ is a pushout of $e$ and $\Delta_L$, and hence that $(s, e')$ is a jointly epimorphic pair: we have the equalities

\[
\begin{align*}
\gamma \circ p_1 \circ s &= f = \gamma \circ p_2 \circ s \\
\gamma \circ p_1 \circ e' &= \gamma \circ e \circ \pi_1 = 0 = \gamma \circ e \circ \pi_2 = \gamma \circ p_2 \circ e'
\end{align*}
\]

and so $\gamma \circ p_1 = \gamma \circ p_2$. This means that $Q \cong C_e$.

Finally by Lemma 5.6 we know that $C_e = 0$ iff $(\tilde{e}: M \to L, \xi)$ is perfect, and this proves our claim. $\square$

**Proposition 5.9.** Consider a regular epimorphism of crossed modules

$$(M \xrightarrow{\tilde{e}} L, \xi) \xrightarrow{(1, \xi)} (M' \xrightarrow{\tilde{e}'} L, \xi').$$

Then $f$ considered as a morphism in $\mathcal{A}$ is a central extension (with respect to $\text{Ab}(\mathcal{A})$, see Definition 2.1).

**Proof.** Since $(\tilde{e}: M \to L, \xi)$ is a crossed module we have that $[K_{\tilde{e}}, M] = 0$. From the commutativity of the triangle

we can construct a monomorphism $K_f \hookrightarrow K_{\tilde{e}}$. Since Higgins commutators are monotone, this in turn induces a monomorphism $[K_f, M] \hookrightarrow [K_{\tilde{e}}, M]$. Recall
(Example 5.2) that \([K_\mathcal{L}, M] = 0\). Hence also \([K_f, M]\) is trivial, and therefore \(f\) is a central extension (as a morphism in \(\mathcal{A}\), with respect to \(\text{Ab}(\mathcal{A})\)—see 2.9).

**Proposition 5.10.** If \((\hat{\varphi} : M \to L, \xi)\) is a perfect crossed module, then the morphism \((\delta_M, 1_L)\) in \((\mathcal{C})\) is a central extension of \(L\)-crossed modules.

**Proof.** We know from the proof of Proposition 5.8 that \(\delta_M \times 1_L\) in \((\mathcal{C})\) is a regular epimorphism. Since, coming from a crossed square, it is also the differential of a crossed module, it is a central extension in \(\mathcal{A}\) with respect to the Birkhoff subcategory \(\text{Ab}(\mathcal{A})\). Via Corollary 3.4, we may picture its kernel in \(\text{Pt}_L(\mathcal{A})\) as the following pullback in \(\mathcal{A}\):

\[
\begin{array}{ccc}
K_{\delta_M} \times_1 L & \xrightarrow{\bar{\varphi}} & (L \oplus M) \times_1 L \\
\downarrow \varpi & & \downarrow (\oplus) \\
L & & L \\
\delta_M \times_1 L & \xrightarrow{\bar{\varphi}} & M \times_1 L \\
\end{array}
\]

The morphism \(\bar{\varphi}\) is a central extension, as a pullback of \(\delta_M \times 1_L\); on the other hand, it is split by \(\varpi\). Hence by Lemma 2.8 it is a trivial extension, which by 2.13 implies that the action of \(L\) on \(K_{\delta_M}\) is trivial. This proves our claim. \(\square\)

**Proposition 5.11.** Any central extension of \(L\)-crossed modules

\[
(M \xrightarrow{\hat{\varphi}} L, \xi) \xrightarrow{(f, 1_L)} (M' \xrightarrow{\hat{\varphi}'} L, \xi')
\]

induces a crossed square

\[
\begin{array}{ccc}
M & \xrightarrow{f} & M' \\
\downarrow \hat{\varphi} & & \downarrow \hat{\varphi}' \\
L & & L
\end{array}
\]

**Proof.** The first step is to prove that \([M \times L, K_f \times 1_L] = 0\). We use the join decomposition formula of Proposition 3.7 to see that

\[
[M \times L, K_f \times 1_L] = [M, K_f \times 1_L] \cap [L, K_f \times 1_L] \cap [M, L, K_f \times 1_L]
\]

and we show that each component is trivial:

- notice that \(K_f = K_f \times 1_L\) since \(f\) is the pullback of \(f \times 1_L\);
- since \((f, 1_L)\) is a central extension, we know that \([L, K_f] = 0\);
- from Proposition 5.9 it follows that \(f\) is a central extension with respect to \(\text{Ab}(\mathcal{A})\), and therefore \([M, K_f] = 0\);
- since both \(K_f\) and \(M\) are normal subobjects of \(M \times L\), via [23 Section 4] the Smith is Huq condition implies that \([K_f, M, M \times L] \leq [K_f, M] = 0\), which in turn implies \([M, L, K_f] = 0\) since this is a subobject of the previous one.

Now consider the extension \(f \times 1_L\) (it is a regular epimorphism because \(f\) is so):

\[
[M \times L, K_f \times 1_L] = 0
\]

we deduce that \(f \times 1_L\) is a central extension with respect to \(\text{Ab}(\mathcal{A})\) and therefore it is the differential of a crossed module.

We now use the fact that in \(\text{Grpd}(\mathcal{A})\) the central extensions (with respect to \(\text{Ab}(\text{Grpd}(\mathcal{A}))\)) are computed pointwise, that is they are couples of central extensions in \(\mathcal{A}\) (with respect to \(\text{Ab}(\mathcal{A}))\); this is shown in Proposition 4.1 of [5]. Since
both $f \times 1_L$ and $1_L$ are central with respect to $\text{Ab}(\mathcal{A})$, the lower square in the diagram

\[
\begin{array}{ccc}
M & \xrightarrow{f} & M' \\
\downarrow{k_d} & & \downarrow{k_{d'}} \\
M \times L & \xrightarrow{f \times 1_L} & M' \times L \\
\downarrow{c} & & \downarrow{c'} \\
L & \xrightarrow{1_L} & L
\end{array}
\]

is a central extension in $\text{Grpd}(\mathcal{A})$ (with respect to $\text{Ab}(\text{Grpd}(\mathcal{A}))$) and therefore it is the differential of an internal crossed module in $\text{Grpd}(\mathcal{A})$. This means that its denormalisation is a double groupoid and therefore the square we are interested in is an internal crossed square.

We can now use this interpretation of central extensions of $L$-crossed modules in terms of crossed squares in order to prove the following result, of which we show the two implications in separate propositions.

**Theorem 5.12.** In a semi-abelian category that satisfies the Smith is Huq condition, an $L$-crossed module is perfect iff it admits a universal central extension.

**Proposition 5.13.** Every perfect $L$-crossed module has a universal central extension.

**Proof.** Let $(\hat{c}: M \to L, \xi)$ be a perfect $L$-crossed module and consider the crossed square

\[
\begin{array}{ccc}
L \otimes M & \xrightarrow{\delta_M} & M \\
\downarrow{\phi} & & \downarrow{\delta} \\
L & \xrightarrow{1_L} & L
\end{array}
\]

By Proposition 5.10, $(\delta_M, 1_L)$ is a central extension of $L$-crossed modules. Now we want to show that this central extension is universal—that is, it is initial among all central extensions of $(\hat{c}: M \to L, \xi)$. So consider another central extension

$(\overline{M} \xrightarrow{\overline{f}} L, \overline{\xi}) \xrightarrow{(\overline{f}, 1_L)} (M \xrightarrow{\hat{c}} L, \xi)$.

Due to Proposition 5.11 we know that also

\[
\begin{array}{ccc}
\overline{M} & \xrightarrow{\overline{f}} & M \\
\downarrow{\overline{c}} & & \downarrow{c} \\
L & \xrightarrow{1_L} & L
\end{array}
\]

is a crossed square. Now it suffices to use the universal property of the non-abelian tensor product (see [13]) to conclude that there exists a unique morphism $\phi: L \otimes M \to \overline{M}$ such that the diagram

\[
\begin{array}{ccc}
L \otimes M & \xrightarrow{\delta_M} & M \\
\downarrow{\phi} & & \downarrow{\delta} \\
\overline{M} & \xrightarrow{\overline{c}} & \overline{M} \\
\downarrow{\overline{c}} & & \downarrow{\delta} \\
L & \xrightarrow{1_L} & L
\end{array}
\]
commutes and the actions are respected. This implies that \((\delta_M, 1_L)\) is initial as a central extension of \(L\)-crossed modules over \((\bar{\varphi}: M \to L, \xi)\).

\[ \text{Proposition 5.14. } \text{In a universal central extension of } L\text{-crossed modules} \]

\[ (M \xrightarrow{\delta} L, \xi) \xrightarrow{(f, 1_L)} (M' \xrightarrow{\delta'} L, \xi') \]

both the domain and the codomain are perfect objects. In particular, any object that admits a universal central extension is perfect.

\[ \text{Proof. Consider an } L\text{-crossed module } (\bar{\varphi}: M \to L, \xi) \text{ and an abelian object } A. \]

Since \(A\) is abelian, \((0: A \to L, \tau^L_A)\) is an \(L\)-crossed module. We can construct the crossed module \((\pi^L_M \circ \tau^L_A): A \times M' \to L, \xi_{A \times M'}\) where the action \(\xi_{A \times M'}\) is induced by the universal property of the product as shown in the diagram

\[ \begin{array}{ccc}
Lb(A \times M') & \xrightarrow{Lb(M')} & LbM' \\
\downarrow \xi_{A \times M'} & & \downarrow \xi' \\
\pi_A \times M' & \xrightarrow{\pi_M'} & M'.
\end{array} \]

(D)

In order to see that this is an \(L\)-action it suffices to use the naturality diagrams for \(\eta\) and \(\mu\) and the fact that both \(\tau^L_A\) and \(\xi'\) are \(L\)-actions. Similarly, to see that this gives rise to an \(L\)-crossed module it suffices to use that both \((\bar{\varphi}: M' \to L, \xi')\) and \((0: A \to L, \tau^L_A)\) are so.

Now consider the triangle

\[ \begin{array}{ccc}
A \times M' & \xrightarrow{\pi_M'} & M' \\
\downarrow \bar{\varphi} \circ \pi_M' & & \downarrow \bar{\varphi}' \\
L & \xrightarrow{\delta'} & M'.
\end{array} \]

This is a morphism of \(L\)-crossed modules (due to (D)) which is a regular epimorphism: we want to follow Remark 5.4 and show that it is a central extension by proving that its kernel has a trivial \(L\)-action. But its kernel is simply \((0: A \to L, \tau^L_A)\): to see this is suffices to use the description of kernels in \(\text{XMod}_L(\mathcal{A})\), to notice that \(A = K_{\pi_M'}\) in the base category \(\mathcal{A}\) and to show the commutativity of the square on the left in the diagram

\[ \begin{array}{ccc}
LbA & \xrightarrow{1_L \times \beta_{(1_A, 0)}} & Lb(A \times M') \\
\downarrow \tau^L_A & & \downarrow \xi_{A \times M'} \\
A \times M' & \xrightarrow{\pi_M'} & M'.
\end{array} \]

We conclude that, since its action is trivial, \((\pi_M', 1_L)\) is a central extension.

Now suppose that

\[ \begin{array}{ccc}
M & \xrightarrow{\delta} & L, \xi \\
\downarrow (f, 1_L) & & \downarrow (f, 1_L) \\
M' & \xrightarrow{\delta'} & L, \xi'.
\end{array} \]
is a universal central extension of $L$-crossed modules. By definition, we have a unique morphism

\[
(M \xrightarrow{\bar{\varepsilon}} L, \xi) \xrightarrow{(g, f), 1_L} (A \times M' \xrightarrow{\bar{\varepsilon}' \circ \pi_{M'}} L, \xi_{A \times M'}) \xrightarrow{(f, 1_L)} (M' \xrightarrow{\bar{\varepsilon}'} L, \xi')
\]

from this extension to the one just defined. Let us focus on this induced morphism: what can we say about $g: M \to A$? It is the unique morphism that makes $\bar{\varepsilon}' \circ \pi_{M'}$ a morphism of $L$-crossed modules, that is such that the following squares commute.

The first one does so for each choice of $g$, whereas the second one will iff

\[
\begin{array}{ccc}
\varepsilon & \xrightarrow{\overline{\eta}} & L \\
\downarrow & & \downarrow \\
A \times M' & \xrightarrow{\bar{\varepsilon}' \circ \pi_{M'}} & L
\end{array}
\]

\[
\begin{array}{ccc}
L \varepsilon M & \xrightarrow{1_{L \varepsilon} g} & L \varepsilon A \\
\downarrow & & \downarrow \\
M & \xrightarrow{\varepsilon} & A
\end{array}
\]

commutes. Now, since

\[
0 \longrightarrow L \circ M \xrightarrow{i_{L, M}} L \varepsilon M \xrightarrow{\pi_{L \varepsilon M} \overline{\eta}_{L \varepsilon M}} M \longrightarrow 0
\]

is a split short exact sequence, we have that $\left(\overline{\eta}_{L \varepsilon M}^L\right): (L \circ M) + M \to L \varepsilon M$ is an epimorphism. Hence the commutativity of (E) is equivalent to the commutativity of the same diagram composed with this epimorphism. This amounts to having that $g \circ \xi_{i_{L, M}} = 0$, which is another way to say that $g([L, M]) = 0$. The morphism $g$ is unique in $\text{Hom}(M, A)$ with this property.

Now fix $A = M/[L, M]$, which is an abelian object by Lemma 4.3. We are going to deduce that $[L, M] = M$. Notice that both the quotient $g = q: M \to M/[L, M]$ and the zero morphism $g = 0$ satisfy the condition $g([L, M]) = 0$. We may thus conclude that $g = 0$, so that $[L, M] = M$. This means that $(\check{\varepsilon}: M \to L, \xi)$ is perfect and consequently $(\check{\varepsilon}': M' \to L, \xi')$ is perfect too, as a quotient of a perfect object.

**Proof of Theorem 5.12.** Combine the two previous propositions.

**6. Galois theory interpretation, quasi-pointed setting**

The aim here is to use the coinvariants reflector to construct a Birkhoff subcategory of $\textbf{XMod}_L(\mathfrak{A})$ with respect to which we find the “right” class of central extensions of $L$-crossed modules. In [13], the author solved this problem in the case of $\mathfrak{A}$ being the category of Lie algebras.

In the current section, we work in $\textbf{XMod}_L(\mathfrak{A})$, which forces us to take into account the lack of a zero object—see [13]. Here and there we may simplify the situation by making constructions in the more benign context of $\textbf{XMod}(\mathfrak{A})$. In the
Proposition 3.14. The intersection is the subobject of $M$.

Definition 6.1. Given an internal crossed module $(\tilde{\partial} : M \to L, \xi)$, we write $K_{\tilde{\partial}}$ for the kernel of $\tilde{\partial}$, and let $[L, M] \hookrightarrow M \rtimes \xi L$ be the commutator induced by $\xi$ as in Proposition 3.13.

We say that $(\tilde{\partial} : M \to L, \xi)$ is action-acyclic when $K_{\tilde{\partial}} \cap [L, M] = 0$. Here the intersection is the subobject of $M$ defined via the pullback

\[
\begin{array}{ccc}
K_{\tilde{\partial}} \cap [L, M] & \overset{\kappa_{\tilde{\partial}, [L, M]}}{\to} & [L, M] \\
\downarrow & & \downarrow \\
K_{\tilde{\partial}} & \overset{\kappa_{\tilde{\partial}}}{\to} & M.
\end{array}
\]

The idea behind this definition is that the action has no cycles (elements of $K_{\tilde{\partial}}$) in its image.

We will denote $\text{AAXMod}_L(\Lambda)$ the full subcategory of $\text{XMod}_L(\Lambda)$ whose objects are the action-acyclic crossed modules.

Notice that since $i$ is the diagonal of the pullback of a kernel along another kernel, it is itself a kernel. Furthermore, the intersection $K_{\tilde{\partial}} \cap [L, M]$ is abelian, because $K_{\tilde{\partial}}$ is the kernel of a central extension as in Example 5.2. This allows us to use the following lemma:

Lemma 6.2. $A \in \text{Ab}(\Lambda)$ iff $(0 : A \to 0, \tau_A)$ is an internal crossed module.

Proof. An internal groupoid structure on the reflexive graph $\xymatrix{A \ar[r] & 0}$ is the same thing as internal monoid structure on $A$, which in the current context amounts to an internal abelian group structure. $\square$

Construction 6.3. We define the functor $F : \text{XMod}_L(\Lambda) \to \text{AAXMod}_L(\Lambda)$, left adjoint to the inclusion functor $J$.

Given an internal $L$-crossed module $(\tilde{\partial} : M \to L, \xi)$, the sub-crossed module $(0 : (K_{\tilde{\partial}} \cap [L, M])) \to 0, \tau^0_{K_{\tilde{\partial}} \cap [L, M]}$ is obtained via Lemma 6.2. The inclusion between the two crossed modules is given by the morphism $(i, 0) \in \text{XMod}(\Lambda)$:

\[
\begin{array}{ccc}
0\kappa_{K_{\tilde{\partial}} \cap [L, M]} & \overset{0\kappa_{K_{\tilde{\partial}} \cap [L, M]}}{\to} & L \cap M \\
\tau^0_{K_{\tilde{\partial}} \cap [L, M]} & \downarrow & \downarrow \xi \\
(K_{\tilde{\partial}} \cap [L, M]) & \overset{i}{\to} & M \\
\downarrow & & \downarrow \\
0 & \overset{0}{\to} & 0 \\
\end{array}
\]

The image of $(\tilde{\partial} : M \to L, \xi)$ through $F$ is given by the cokernel in $\text{XMod}(\Lambda)$ of the previous inclusion, that is

\[
\xymatrix{\xymatrix{M} \ar[r]_{\tau^0_{K_{\tilde{\partial}} \cap [L, M]}} & L, \xi}
\]

where the action $\xi$ is obtained as follows: first we pass to the category of points and take the cokernel there

\[
\begin{array}{ccc}
0 & \to & K_{\tilde{\partial}} \cap [L, M] & \overset{\kappa_{\tilde{\partial}, [L, M]}}{\to} & K_{\tilde{\partial}} \cap [L, M] & \overset{0}{\to} & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \to & M & \overset{k_p}{\to} & X & \overset{p}{\to} & L & \overset{0}{\to} 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \to & K_{\tilde{\partial}} & \overset{k_{\tilde{\partial}}}{\to} & C(k_{\tilde{\partial}}) & \overset{\tau}{\to} & L & \overset{0}{\to} 0,
\end{array}
\]

$$\text{(F)}$$
then we go back to the associated action \( \bar{\xi} \) given by the diagram

\[
\begin{array}{c}
\xymatrix{
L \ar[r] & L + M \\
K \ar[r] \ar[u]^{1_L \cdot c_i} & L \\
M \ar[r] \ar[u] & X \\
M \ar[u]_{k_p} & C(k_p, t) \ar[u]_{p} & L \ar[u]_{\tau} \\
M \ar[u]_{k_p} & C(k_p, t) \ar[u]_{p} & L \ar[u]_{\tau} \\
\end{array}
\]

Figure 6.1. \( \bar{\xi} \) is an action.

The first thing we need, is to prove that \( K \cong C_i \); this follows easily from the fact that the dotted arrow in (F) is a regular epimorphism whose kernel is \( i \), all because the lower left square in (F) is a pullback.

At this point one would expect that the action \( \bar{\xi} \) just defined makes the diagram

\[
\begin{array}{c}
\xymatrix{
0b(K \cdot [L, M]) \ar[r]^{0b_i} & L \ar[r]^{1_L \cdot c_i} & LbM \\
K \ar[r]^{(\bar{\xi})} \ar[u]^{0b_i} & LbM \ar[u]^{1_L \cdot c_i} & LbM \ar[u]^{(\bar{\xi})} \\
(K \cdot [L, M]) \ar[r]^{1_L \cdot c_i} & M \ar[r]^{(\bar{\xi})} & M \ar[u]^{(\bar{\xi})} \\
M \ar[r]_{(\bar{\xi})} & M \ar[r]_{(\bar{\xi})} & M \\
\end{array}
\]

commute and indeed this can be shown by using the diagram in Figure 6.1. The morphism \( \bar{\xi} \) is induced via the universal property of the cokernel of \( i \):

\[
\begin{array}{c}
\xymatrix{
(K \cdot [L, M]) \ar[r]^{i} & M \ar[r]^{c_i} & M \\
M \ar[r]_{(\bar{\xi})} & M \ar[r]_{(\bar{\xi})} & M \\
0 \ar[r] & L \ar[r]_{(\bar{\xi})} & L \\
0 \ar[r] & L \ar[r]_{(\bar{\xi})} & L \\
\end{array}
\]

The fact that it is an internal crossed module is easy to show: it suffices to use that \( \bar{\xi} \cdot [L, \xi] \) is an internal crossed module and that both \( q \cdot q \) and \( 1_L \cdot q \) are (regular) epimorphisms (by Lemma 5.11 in [30]). From the commutativity of \( (*) \) and \( (**) \) we conclude that

\[
\begin{array}{c}
\xymatrix{
(M \ar[r]^{(c_i, 1_L)} & M \ar[r]^{(\bar{\xi})} & M \\
\ar[u]^{(\bar{\xi})} & (\bar{\xi}) & L, \xi \ar[u]^{(\bar{\xi})} \\
\end{array}
\]

is a morphism of \( L \)-crossed modules. Furthermore it can easily be checked that this morphism has the universal property of the cokernel of \( (i, 0) \) in \( XMod(\Lambda) \).
Lemma 6.4. The category $\text{AAXMod}_L(\mathfrak{A})$ is Birkhoff in $\text{XMod}_L(\mathfrak{A})$.

Proof. This proof follows the pattern of Proposition 3.15 by Corollary 5.7 in [10], it suffices that the subfunctor of $\text{1XMod}(\mathfrak{A})$ determined by the construction in Definition 4.2 preserves regular epimorphisms. So, consider a morphism as in

$$(M \xrightarrow{\tilde{\varphi}} L, \xi) \xrightarrow{(f, 1_L)} (M' \xrightarrow{\tilde{\varphi}'} L, \xi')$$

which is also a regular epimorphism in $\text{XMod}_L(\mathfrak{A})$. Due to Lemma 4.2, this means that $f$ is a regular epimorphism in $\mathfrak{A}$. Consider the cube

Its front and back faces are pullbacks by definition of the intersection, while the bottom face is a pullback since $(f, 1_L)$ is a morphism of crossed modules over $L$. Hence the top square is a pullback as well. It follows that $\phi$ is a regular epimorphism, because so is $[1_L, f]$. □

A functor is protoadditive when it preserves split short exact sequences. This concept was introduced and studied in [15], in the context of homological categories. Here we just need to explain that in a quasi-pointed category, kernels and cokernels are defined by pulling back and pushing out along the zero object: see [3].

Theorem 6.5. The reflector $F$ is protoadditive.

Proof. The proof is made of the following steps:

1. Show that the functor that sends an $L$-crossed module $(\tilde{\varphi}: M \to L, \xi)$ to the commutator $[L, M]$ is protoadditive;
2. show that the functor $(\tilde{\varphi}: M \to L, \xi) \mapsto (K_L \times [L, M])$ is protoadditive;
3. use the $3 \times 3$-Lemma to conclude that $F$ is protoadditive.

For what regards (1) the aim is to prove that any split short exact sequence of $L$-crossed modules

$$(K \xrightarrow{0} L, \xi) \xrightarrow{(k, 1_L)} (M \xrightarrow{\tilde{\varphi}} L, \xi) \xrightarrow{(f, 1_L)} (M' \xrightarrow{\tilde{\varphi}'} L, \xi') \quad \text{(G)}$$

induces a split short exact sequence of Higgins commutators

$$0 \xrightarrow{[1_L, k]} [L, K] \xrightarrow{[1_L, f]} [L, M] \xrightarrow{[1_L, g]} [L, M'] \xrightarrow{0} 0$$

From the fact that

$$0 \xrightarrow{f} K \xrightarrow{g} M \xrightarrow{g} M' \xrightarrow{0}$$

is a split exact sequence in the base category, by using Proposition 2.24 in [23] we obtain that

$$0 \xrightarrow{(L \circ K \circ M) \times (L \circ K) \circ (L \circ M)} L \circ M \xrightarrow{1_L \circ f} L \circ M' \xrightarrow{0}$$
is a split exact sequence as well. We have the comparison arrows

\[
\begin{array}{ccc}
0 & \to & (L \circ K \circ M) \times (L \circ K) \\
\downarrow & & \downarrow f \\
0 & \to & K \circ M \\
\downarrow & & \downarrow k \\
0 & \to & M \\
\end{array}
\]

whose images, from right to left, are \([L, M'], [L, M]\) and \([L, K, M] \vee [L, K]\). These images form a split short exact sequence: taking kernels to the left,

\[
\begin{array}{ccc}
0 & \to & (L \circ K \circ M) \times (L \circ K) \\
\downarrow & & \downarrow f \\
0 & \to & K(1_{L,f}) \\
\downarrow & & \downarrow k \\
0 & \to & M \\
\end{array}
\]

we see that the bottom left square is a pullback, since the bottom right vertical arrow is a monomorphism; likewise, the top right square is a regular pushout, so the top left vertical arrow is a regular epimorphism. It follows that \(K(1_{L,f})\) is the image \([L, K, M] \vee [L, K]\) of the left vertical composite. Since \(K\) is central in \(M\)—here we use the underlying crossed module structure—we have \([L, K, M] \leq [M, K, M] \leq [K, M] = 0\), so that \(K(1_{L,f}) = [L, K]\).

For (2), consider the diagram in Figure 6.2. It is trivial that \([1_{L}, f] [1_{L}, g] = 1_{[L,M]}\). Then it remains to show that \(k' = k_f\). Suppose that \(\alpha: A \to K\) satisfies \(f \circ \alpha = 0\). Then \(0 = k_{\circ f} \circ f \circ \alpha = [1_{L}, f] \circ k_{\circ \alpha}\). Since \([1_{L}, k] = k(1_{L,f})\), we have a unique \(\gamma: A \to [L, K]\) such that \([1_{L}, k] \circ \gamma = k_{\circ \alpha}\). Using that \(k_{\circ \alpha}\) is a monomorphism, from the equality \([1_{L}, k] = k_{\circ \alpha}\) we deduce that \(k' \circ \gamma = \alpha\).

Finally, in order to prove (3), consider the diagram in Figure 6.3. Each column is exact by definition of the functor \(F\) and the middle row is exact by hypothesis. From the description of kernels in Remark 4.6 and from the previous step, we deduce that the top row is exact as well. Now it suffices to use the 3 × 3-Lemma to obtain that also the bottom row is exact. 

\[\square\]
Lemma 6.7. An extension that the induced sequence of commutators is split short exact as well.

$F$ preserves products, so it sends the split short exact sequence $(K,K^3)\rightarrow (M,L,\xi)$ into a sequence which is again split exact. Finally by the $AAXMod$-functor $F$ we deduce that the induced sequence of commutators is split short exact as well.

Figure 6.3. $3 \times 3$-diagram in the proof of Theorem 6.5

Remark 6.6. When $\mathcal{A}$ is a strongly protomodular category (see [1]) we can give a simpler proof of the protoadditivity of the functor $F$ by changing the way in which (1) is shown in Theorem 5.9. This proof uses Proposition 5.9 as follows.

Consider a split short exact sequence of $L$-crossed modules as in (1): by Proposition 5.9 we know that $f$ is a central extension in $\mathcal{A}$ (with respect to $Ab(\mathcal{A})$), but since it is also split, it is a trivial extension and hence a product projection. In particular $g$ is a normal monomorphism, and since $\mathcal{A}$ is a strongly protomodular category, it follows that $(g,1_L)$ is a normal monomorphism of $L$-actions: since it is a split monomorphism as well, we see that $(g,1_L)$ is a product inclusion and $(f,1_L)$ is a product projection in $\mathcal{A}^L(\mathcal{A})$.

Notice that in the semi-abelian context, regular epi–reflectors preserve products. In particular, $F$ preserves products, so it sends the split short exact sequence into a sequence which is again split exact. Finally by the $3 \times 3$-Lemma we deduce that the induced sequence of commutators is split short exact as well.

Now, using Lemma 2.8 we can reformulate centrality as follows.

Lemma 6.7. An extension $(f,1_L): (\hat{c}: M \rightarrow L, \xi) \rightarrow (\hat{c}': M' \rightarrow L, \xi')$ is central with respect to $AAXMod_L(\mathcal{A})$ if and only if its kernel

$$K_{(f,1_L)} = (K_{(f,1_L)} \xrightarrow{(f,1_L)} (M \hat{\rightarrow} L, \xi) \xrightarrow{(f,1_L)} (M \hat{\rightarrow} L, \xi')$$

is an action-acyclic crossed module.

Proof. The characterisation of central extensions as those extensions whose kernel lies in the given Birkhoff subcategory is actually valid for protoadditive Birkhoff reflectors in general [15], at least in the homological context; we repeat the argument for the sake of convenience.

The given extension is central iff the projection

$$(r_1,1_L): Eq((f,1_L)) \rightarrow (M \hat{\rightarrow} L, \xi)$$

is a trivial extension. Since $r_1$ is a split epimorphism, we have the diagram

$0 \rightarrow K_{(f,1_L)} \xrightarrow{(r_1,1_L)} Eq((f,1_L)) \xrightarrow{(r_1,1_L)} (M \hat{\rightarrow} L, \xi) \rightarrow 0$

$0 \rightarrow F(K_{(f,1_L)}) \xrightarrow{F((r_1,1_L))} F(Eq((f,1_L))) \xrightarrow{F((r_1,1_L))} F((M \hat{\rightarrow} L, \xi)) \rightarrow 0$
where the vertical morphisms are the components of the unit. Notice that the first row is exact since \( K_{(r_1,1)} = K_{(f,1)} \). Hence the second row is exact, because \( F \) is protoadditive. By definition we have that \((r_1,1)\) is a trivial extension iff the square on the right is a pullback, but this is true iff the vertical morphism on the left is an isomorphism [3, Proposition 7]. □

**Theorem 6.8.** An extension of \( L \)-crossed modules in \( \mathcal{A} \) is central with respect to \( \mathbf{AAXMod}_L(\mathcal{A}) \) if and only if it is a central extension in the sense of Definition 5.3.

**Proof.** This is a consequence of Lemma 6.7 and Proposition 3.14. □

We have to generalise Definition 2.12 to the quasi-pointed [3] exact environment of \( \mathbf{XMod}_{L}(\mathcal{A}) \). There seems to be no single categorically sound approach to this; so we stick with the following ad-hoc interpretation:

**Definition 6.9.** Given an \( L \)-crossed module \((\tilde{\partial} : M \to L, \xi)\), we say that it is perfect (with respect to \( \mathbf{AAXMod}_L(\mathcal{A}) \)) whenever its underlying action is perfect (with respect to \( \mathbf{TrivAct}_L(\mathcal{A}) \)), which means that \([L, M] = M\).

The aim of the next section is to make this more natural: we set up a Galois theory with respect to which both the central extensions and the perfect objects agree with those needed in Section 5.

### 7. Galois theory interpretation, pointed setting

Given an internal crossed module \((\tilde{\partial} : M \to L, \xi)\), Lemma 6.3 tells us that the quotient \( M/[L, M] \) is always an abelian object. Clearly, this induces a functor determined by

\[
F : \mathbf{XMod}(\mathcal{A}) \to \mathbf{Ab}(\mathcal{A}) : (M \xrightarrow{\xi} L, \xi) \mapsto \frac{M}{[L, M]},
\]

which has a right adjoint given by the inclusion of abelian objects as particular crossed modules. Indeed, via Lemma 6.2 we obtain a functor

\[
G : \mathbf{Ab}(\mathcal{A}) \to \mathbf{XMod}(\mathcal{A}) : A \mapsto (A \xrightarrow{0} 0, 0^A)\]

which allows us to view \( \mathbf{Ab}(\mathcal{A}) \) as a subcategory of \( \mathbf{XMod}(\mathcal{A}) \). As before, we may follow the pattern of Proposition 5.13 to show that \( F \) is a Birkhoff reflector with right adjoint \( G \); this follows immediately from Corollary 5.7 in [13] and the fact that the commutator functor \([L, -]\) preserves regular epimorphisms. Thus we see:

**Proposition 7.1.** The category \( \mathbf{Ab}(\mathcal{A}) \) is a Birkhoff subcategory of \( \mathbf{XMod}(\mathcal{A}) \), with reflector \( F \) whose right adjoint is \( G \). □

**Remark 7.2.** If \( \mathbf{XMod}(\mathcal{A}) \) has enough projectives then so does \( \mathcal{A} \), since \( \mathcal{A} \) is included as a Birkhoff subcategory and Birkhoff reflectors preserve the property of existence of enough projectives. (Indeed, any left adjoint whose right adjoint preserves regular epimorphisms does so.)

Proving the converse (that \( \mathbf{XMod}(\mathcal{A}) \) has enough projectives if so does \( \mathcal{A} \) is more difficult. By general results on functor categories we know that if \( \mathcal{A} \) has enough projectives then the category of reflexive graphs in \( \mathcal{A} \) has enough projectives as well. The claim now follows from the same argument as above:

**Corollary 7.3.** Suppose \( \mathcal{A} \) is semi-abelian with (SH) and enough projectives. An internal crossed module \((\tilde{\partial} : M \to L, \xi)\) of \( \mathcal{A} \) is perfect (with respect to the Birkhoff subcategory \( \mathbf{Ab}(\mathcal{A}) \) of \( \mathbf{XMod}(\mathcal{A}) \)) iff it admits a universal central extension (with respect to the Birkhoff subcategory \( \mathbf{Ab}(\mathcal{A}) \) of \( \mathbf{XMod}(\mathcal{A}) \)). □
Figure 7.1. Induced morphism of commutators.

We still have to explain why the central extensions and the perfect objects in this sense agree with the definitions above. Once this is clear, we find Theorem 5.12 as a consequence of Corollary 7.3—under the condition that enough projectives exist in $\mathcal{A}$. If $\mathcal{A}$ happens to lack projectives, then Theorem 5.12 stays valid, of course.

**Proposition 7.4.** Given an extension of a crossed module $(\tilde{c} : M \to L, \xi)$, it is a (universal) central extension with respect to the Birkhoff subcategory $\text{Ab}(\mathcal{A}) \to \text{XMod}(\mathcal{A})$, \hspace{1cm} (H)

iff it is a (universal) central extension with respect to the Birkhoff subcategory $\text{AAXMod}_L(\mathcal{A}) \to \text{XMod}_L(\mathcal{A})$. \hspace{1cm} (I)

Before we prove this, we need a lemma:

**Lemma 7.5.** Consider an extension of crossed modules 

\[ (M' \xrightarrow{\tilde{c}'} L', \xi') \xrightarrow{(f,l)} (M \xrightarrow{\tilde{c}} L, \xi) \]  

which is central with respect to (H). Then $l$ is an isomorphism and $(f,l)$ can be considered as an extension of $L$-crossed modules.

**Proof.** Let us start by proving that a morphism as in (J) is a trivial extension with respect to (H) iff

1. the morphism $l$ is an isomorphism,
2. $[f,l] : [M', L'] \to [M, L]$ is an isomorphism.

By definition $(f,l)$ is trivial with respect to (H), if and only if the cube on the right in Figure 7.1 is a pullback in $\text{XMod}(\mathcal{A})$. Since pullbacks are computed levelwise in $\text{XMod}(\mathcal{A})$, this is the same as asking that both the top and the bottom faces are pullbacks in $\mathcal{A}$. Now the top face is a pullback iff $[f,l]$ is an isomorphism; the bottom face is a pullback iff $l$ is an isomorphism as well.

The next step is showing that for any extension (H) which is central with respect to (H), $l$ is an isomorphism. In order to do so, recall that $(f,l)$ is central when there exists an extension

\[ (\widetilde{M} \xrightarrow{\tilde{c}} \widetilde{L}, \tilde{\xi}) \xrightarrow{(g,k)} (M \xrightarrow{\tilde{c}} L, \xi) \]
such that the pullback $(\bar{f}, \bar{l})$ of $(f, l)$ along $(g, k)$ is trivial. By looking at the pullback

\[
\begin{array}{ccc}
\ast & \xrightarrow{r} & M' \\
\downarrow & & \downarrow \\
\ast' & \xrightarrow{l} & M
\end{array}
\]

and by using the condition for trivial extensions obtained above, we know that $\bar{l}$ is an isomorphism. Hence $l$ is an isomorphism as well: on the one hand, $l$ is a regular epimorphism by hypothesis, being part of an extension; on the other hand, it is a monomorphism, since $l$ is so and because pullbacks reflect monomorphisms. 

\[\square\]

**Proof of Proposition 7.4.** We already know that in order for an extension to be central with respect to $(H)$, it has to have an isomorphism in the second component. Let us therefore fix an extension $(f, 1_L)$. Consider its kernel pair in Figure 7.2 and in particular one of the two projections $(r_0, 1_L)$. We will use the following chain of equivalent conditions to obtain the claim:

1. $(f, 1_L)$ is central with respect to $(H)$.
2. $(r_0, 1_L)$ is trivial with respect to $(H)$.
3. $K_{[r_0, 1_L]} = 0$.
4. $[K_{r_0}, L] = 0$.
5. $[K_f, L] = 0$.
6. $(f, 1_L)$ is central with respect to $(I)$.

The equivalence between (i) and (ii) is given by the fact that the extension $(f, 1_L)$ is central with respect to $(H)$ iff it is normal with respect to $(H)$.

To show (ii) iff (iii) we use Lemma 7.5 and the fact that $[r_0, 1_L]$ is already a split epimorphism by hypothesis (it is defined through a kernel pair): this means that it is an isomorphism iff its kernel $K_{[r_0, 1_L]}$ is trivial. Now consider the diagram

\[
\begin{array}{ccc}
[K_{r_0}, L] & \xrightarrow{k_{[r_0, 1_L]}} & [M, L] & \xrightarrow{[r_0, 1_L]} & [M', L] \\
\downarrow & & \downarrow & & \downarrow \\
K_{r_0} & \xrightarrow{k_{r_0}} & M & \xrightarrow{r_0} & M'
\end{array}
\]

(K)

The functor that sends an $L$-crossed module $(\partial : M \to L, \xi)$ to $[M, L]$ is protoadditive (see Theorem 6.5) and hence the first row in (K) is again a split short exact
sequence: this means that $K_{[r_0,1]} \cong [K_{r_0}, L]$, that is (iii) iff (iv). The equivalence between (iv) and (v) is simply given by the vertical isomorphism on the left of the diagram

$$
\begin{array}{ccc}
K_{r_0} & \xrightarrow{k_{r_0}} & M' \\
\downarrow & & \downarrow \\
K_f & \xrightarrow{k_f} & M' \\
\downarrow & & \downarrow \\
K_f & \xrightarrow{k_f} & M
\end{array}
$$

due to the fact that the square on the right is a pullback by construction. The last step is given by Corollary 6.8.

Finally, it is easy to see that a central extension is universal with respect to (H) if and only if it is universal with respect to (I).

Proposition 7.6. An $L$-crossed module $(\tilde{c} : M \to L, \xi)$ is perfect in the sense of Definition 6.9 if and only if it is perfect with respect to the Birkhoff subcategory $\text{Ab}(\mathcal{K})$ when seen as an object in $\text{XMod}(\mathcal{K})$.

Proof. The crossed module $(\tilde{c} : M \to L, \xi)$ is perfect with respect to Definition 6.9 if and only if $[L, M] = M$. This amounts to $M/[L, M] = 0$, which in turn is the same as $F(\tilde{c} : M \to L, \xi) = 0$, that is perfectness with respect to Definition 2.12.
